
Corrugated-Iron House.

for railroad stations, exhibition and temporary buildings, warehouses, railroad freight cars, fire-proof floors, partitions and roofs, gutters, window-shutters.

Fig. 2704 is an elevation of a house made of corrugated sheet-metal upon an iron frame.

I'ron-fur'nace. (*Metallurgy.*) A furnace in which iron ore or the metal is exposed to heat. The purposes and construction are various. The subject is treated under the different heads: BLAST, REDUCING, DESULPHURIZING, DECARBONIZING, PUDDLING, FURNACES. See list under METALLURGY.

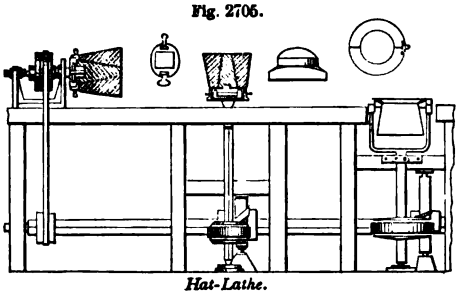
I'ron-ing-board. (*Domestic.*) A laundry implement on which clothes are ironed; sometimes having a special shape, as for bosoms, pantaloons, etc.

I'ron-ing-lathe. (*Hat-making.*) A machine having mandrels carrying blocks on which hats are mounted for ironing. The different blocks and positions shown are for holding the hat while the side, crown, and outside and inside of the brim respectively are ironed.

I'ron-ing-ma-chine'. One for ironing clothes, etc. Specific forms are make for hat-ironing, for hosiery, and for tailors. The example shows one

Digitized by Google

Fig. 2705.



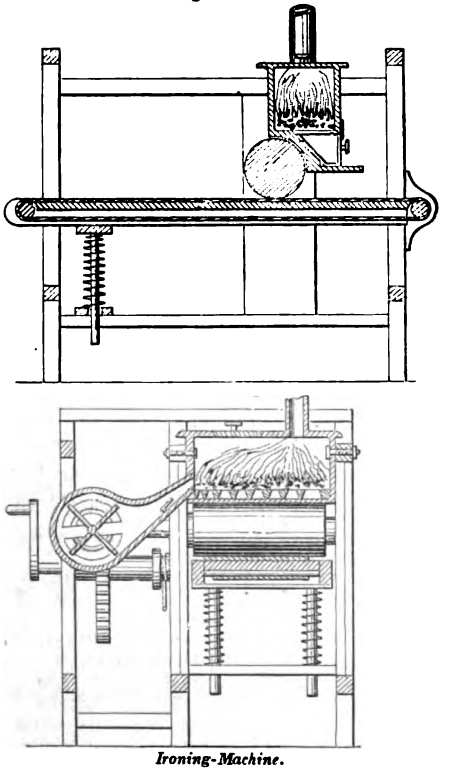
Hat-Lathe.

in which the clothes are carried on the endless belt under the heated roller. The table is depressible to allow the passage of heavy articles. The roller cover is the bottom of the fire-chamber, and the fire is urged by air from a blower driven by the crank which carries the endless apron.

I'ron-liq'uor. (*Dyeing.*) A solution of acetate of iron, used as a mordant by calico-printers.

I'ron-man. (*Cotton-manufacture.*) A name applied to the self-acting mule invented in 1825 by Roberts, of Manchester, England. The working of

Fig. 2706.



Ironing-Machine.

the ordinary mule was confided to the most skillful operatives. The machine by which their services were dispensed with was regarded as a triumph of ingenuity, and was thus named. See MULE.

I'ron-pa'per. A name given to extremely thin sheet-iron, which has been rolled thinner than the finest tissue-paper. In the American Department of the British Exhibition of 1851 very thin specimens were shown, and from this period a lively competition ensued as to who would show the finest and thinnest specimens. The results are mentioned under SHEET-IRON (which see).

I'ron-pipe. Welded iron tubes are made of skelps bent to a circular form, heated to a welding heat in an appropriate furnace, and then drawn on a draw-bench through a pair of jaws with bell mouths. The mouths are opened to receive the end of the skelp, and then closed. The tube is drawn without a mandrel. The sizes are from —

6 inches internal diameter, $\frac{1}{8}$ to $\frac{3}{8}$ inch thick.

$\frac{1}{4}$ inch internal diameter, $\frac{1}{16}$ inch bore.

For *cast-iron water-pipes* the working tension may be $\frac{1}{6}$ of the bursting tension, say, —

Bursting tension . . .	16,500 pounds.
Proof tension . . .	5,500 "
Working tension . . .	2,750 "

The working tension of *cast-iron steam-pipes* should be $\frac{1}{4}$ only of the ultimate tension.

I'ron-rust Ce-ment'. A cement for stopping joints or cracks in iron-work. It consists of iron borings or filings, 112; sal-ammoniac, 1; sulphur, 1; whitening, 4. Mix with water and use. It forms a dense rust. See CEMENT, page 508.

I'ron-sand. 1. (*Pyrotechnics.*) Steel filings, used in pyrotechny for brilliant fire, etc.

2. A variety of octohedral iron ore in grains.

I'ron, Sheet. See SHEET-IRON.

I'ron-stone Chi'na. One of the contributions of Wedgwood to the ceramic art.

The materials of the Staffordshire ware are calcined flints and clay. The flints are burned in kilns, and then, while hot, quenched in water, by which they are cracked through their whole substance. After being quenched they are ground, with water, in mills resembling the arrastra. The mill is a hollow cylinder of wooden staves bound with hoops, and having a bottom of blocks of chert; the mill-shaft is perpendicular and has two horizontal arms, between which are laid loose blocks of chert, which are moved round on the bed-stone as the arms revolve, and thus grind the flint with water to the consistence of cream.

The clay, from Dorsetshire and Devonshire, is mixed with water, and in this state, as well as the flint, is passed through fine sieves to separate the grosser particles. The flint and clay are now mixed by measure, and the mud or cream is passed again through a sieve, in order to render the mixture more complete.

In this state it is called *slip*, is then evaporated to a proper consistence in long brick troughs, and tempered in the pug-mill. Cups, pots, basins, and other round articles are turned rough on the horizontal potter's-wheel, and when half dried are again turned in a lathe. They are then fully dried in a stove, and the remaining roughnesses are afterwards removed by friction with coarse paper. Articles that are not round, and the round ones that have embossed designs on their surface, are made of thin sheets of clay rolled out like dough, and then pressed into molds of plaster of paris; the molds, being previously dried, absorb the superficial moisture of the clay, and thus allow it to part from them without injury. The two or three separate pieces composing the article are then united by means of slip. Spouts and handles of jugs and teapots are united with the body of the vessel in the same way. Small handles, beadings, moldings, etc., are formed by means of an iron cylinder having its bottom perforated, so as to mold the clay, as it passes through, into the required figure. A piston descends slowly

Digitized by Google

in the cylinder, and drives the clay out through the perforation; it is then cut off in lengths. To form a plate, a lump of clay is beaten or rolled into a flat cake, which is then laid on a mold turned to the shape of the upper surface of the plate. A rotary motion is given to the mold, and an earthenware tool representing a section of the bottom of the plate is pressed on it. Cups, saucers, and basins, when rough turned, are dried on the block to keep them from warping. The ware, being thoroughly dried, is packed into saggars and burned in the kiln to biscuit. Patterns for flat or nearly flat surfaces are put on by printing the pattern from a copperplate with an ink composed of oxide of cobalt, oxide of iron, or other coloring matter, mixed with oil. The impression is taken on tissue-paper, and is applied without drying to the surface of the biscuit, and slightly rubbed to make the print adhere; the biscuit is then soaked in water till the paper may be stripped off, leaving the print or pattern behind. The ware is then dipped in the glaze, which is a mixture of flint slip and white-lead, and the bibulous quality of the biscuit causes a sufficient quantity to adhere; the piece is then dried and again passed into the furnace, which brings out the colors of the pattern, and at the same time vitrifies the glaze.

The finest patterns for curved surfaces are applied after the glazing has been completed, by taking the impressions from the copperplate on a flexible strap covered with a strong gelatinous mixture of glue and treacle. This strap is then pressed on the ware, and gives the impression in glue; the coloring powder is then dusted over it, and a sufficient portion adheres to the damp parts to give the pattern, after having been again in the kiln. The more elaborate patterns on earthenware, and all those on porcelain, are finished by penciling in.

Iron Vessel. The first iron boat was built in 1787, by J. Wilkinson, of Bradley Forge, England. It was 70 feet long, 6 feet 8½ inches beam. The plates were $\frac{1}{8}$ inch, secured by rivets. The stem and stern-post were of wood, the beams of elm planks. Her weight was 8 tons, capacity 32 tons; she drew 8 to 9 inches of water when light, and plied on the Birmingham Canal.

An iron pleasure-boat was launched on the Mersey in 1815 by T. Jevons of Liverpool. It was scuttled by jealous shipbuilders, and an iron *life-boat* launched by the same person in 1817 experienced the same fate.

The first iron steam-vessel launched and put to sea was projected and built for A. Manby of Staffordshire, for the river Seine, in 1821. She took in a cargo of linseed-oil and iron castings, and was navigated direct from London to Havre, and from that port proceeded to Paris, where she discharged her cargo. She navigated the Seine for many years, and may yet.

The iron steamboat "Alburkah," for the Lander Expedition up the Niger, was built in 1831. She was 70 feet long, 13 feet beam, and 6½ feet deep. When launched she drew 9 inches of water; when equipped she drew 40 inches. She was navigated to the scene of her exploits, twice ascended the river, and her ribs upon the strand of Clarence Cove were visible but a few years since, and may yet remain. Her engines were 16 horse-power. Her weight, without engine, 33,600 pounds.

The "Garry Owen" was the first iron vessel with water-tight bulkheads; suggested by C. W. Williams. See BULKHEAD.

Iron vessels for America, Ireland, France, India, and China were built in Scotland and on the Mersey, 1833–39.

The iron steam-vessels "Nemesis" and "Phlegethon" were used in the villainous Opium War of 1842. They were not the last vessels built on the Clyde for piratical expeditions.

The "Ironsides" was the first iron sailing vessel of any magnitude employed for sea voyages.

The "Great Britain," built at Liverpool, was the boldest effort in iron shipbuilding in her time, but was eclipsed by the "Leviathan," afterwards renamed the "Great Eastern," which was built from the designs of Brunel, by Russell & Co., at Millwall, on the Thames.

She was commenced in 1853, and was four years in building.

The proportions and capacity are as follows:—

Length between perpendicular	680	feet.
Length on upper deck	692	"
Breadth of the hull	83	"
Breadth, including paddle-boxes	118	"
Depth of the hull	60	"
Weight of iron in the hull	16,800,000	pounds.
Weight with engines, stores, and complement	56,000,000	"
Draft, loaded	30	feet.
Number of iron plates	10,000	
Number of rivets	3,000,000	
Passenger capacity, first class	800	
Second class	2,000	
Third class	1,200	
	4,000	
Crew and engineers	400	
Paddle-wheels, in diameter	56	feet.
Float-boards, in length	13	"
Screw-propeller, diameter	24	"
Screw-propeller, length of shaft	160	"

The design was to make the "Great Eastern" on the principle of a wrought-iron girder. For this purpose, the bottom, sides, and deck are cellular, and each shell water-tight. The distance between the shells is 34 inches, and is traversed by 35 ribs or webs running longitudinally from stem to stern. Similar webs traverse the cellular deck.

An elaborate system of transverse and longitudinal bulkheads divides the vessel into numerous compartments, so arranged as to form the required spaces for engines, boilers, coals, cargo, and passengers. Of these are 10 or 12 transverse, water-tight bulkheads, which have no openings below the lower deck.

The means of propulsion are paddles, screw, and sails; six masts carrying 6,500 yards of canvas.

The details of the donkey and pumping engines, gas and telegraph apparatus, the fleet of boats, and the two steam-tenders, 90 feet long, hanging from davits abaft the paddle-boxes, are highly interesting, and may be found in the journals of the day and in works specially devoted to marine and steam engineering.

Iron-wheel. See CARRIAGE-WHEEL; CAR-WHEEL.

Iron-work Paint. Graphite and hot coal-tar.

Solution of silicate of soda (20° Baume), 2 parts; zinc oxide, 1 part.

Asphaltum and resin, equal parts, dissolved in spirits of turpentine.

For machinery: caoutchouc, 2 pounds; resin, 4 pounds; shellac, 2 pounds; 5 gallons of benzine.

For wrought-iron structures: scrub with wire brushes, fill crevices with a putty of litharge, linseed-oil, varnish, and white lead; repeat the brushing; apply a paint of white-lead, 300 pounds; crude linseed-oil, 10 gallons; boiled linseed-oil, 2 gallons; turpentine, 1¼ gallons. Blow white sand on to a second coat of the same.

Digitized by Google

Rub the work with heavy petroleum.

Galvanizing-paint: zinc powder and oil varnish.

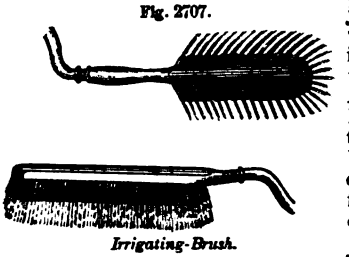
Rub the red-hot iron with wax, tallow, pitch, or coal-tar. See also VARNISH.

For bright-work; during transportation and at sea: tallow, with a little white-lead to give it consistence. It is rubbed off when the machine is set up, or the vessel is nearing port.

Ir-reg'u-lar Wheel. Several varieties of gears may be termed irregular; but the variability of each is in regular terms, if the motion of the wheel be continuous; the parts passing through recurrent series of consecutive changes. See ANGULAR WHEEL; CAM GEAR-WHEEL; ECCENTRIC WHEEL; ELLIPTICAL WHEEL; INTERMITTENT WHEEL; MUTILATED WHEEL; SCROLL-WHEEL; SECTOR-WHEEL; SPIRAL WHEEL; VARIABLE WHEEL.

Ir'ri-gat-ing-brush. One having concealed holes through which jets or spray of water passes, in the line of the bristles. An elastic tube leads the water to the brush. It is especially used for cleaning carriages.

Fig. 2707.



Irrigating-Brush.

Ir'ri-ta'tion-in'strument. An acicular instrument used to penetrate the skin as a local irritant. Sometimes used to introduce a vesicatory liquid beneath the epidermis. See ACUPUNCTURATOR; HYPODERMIC SYRINGE.

I'sin-glass. A fine kind of glue or hardened gelatinous composition, composed of dissolved membraneous animal tissues.

The genuine is made in Russia from the sounds and air-bladders of sturgeon, but other kinds are made either of clean scraps of hide, etc., or the purified jelly derived from the digestion of skins, hoofs, horns, etc. In the latter case, it is glue purified by the discharge of fetid smells and putrid flavors.

I-sod'o-mon. A style of masonry in which the face is formed of squared blocks, the courses of equal hights, and the filling of smaller blocks in courses.

The *pseudisodomon* had courses of varying hight. See MASONRY.

I-so-met'ri-cal Pro-jec'tion. A mode of drawing machines or buildings, in which the plan and elevations are shown in one view. Three planes are projected at an equal angle upon a single plane.

I-tal'ian I'ron. A laundress's smoothing-iron for fluting and smoothing frills.

I-tal'ian Roof. A hip-roof.

I-tal'ic. Inclined type of a peculiar form, as, —

Italic type is said to have been copied from the handwriting of Petrarch, by the famous printer Aldus Manutius. He obtained a patent for the use of this character in type from Pope Leo X., surnamed The Great.

I'vo-ride. An artificial ivory. A vulcanite whitened by abundant quantity of some white material. See IVORY, ARTIFICIAL.

I'vo-ry. Specifically, the material constituting the tusk of the elephant.

In a more general sense the term includes the tusks of the walrus, narwhal, and even the teeth of some other cetacea.

The African ivory is preferred to the Asiatic; it has a greater proportion of animal matter, and is less liable to discoloration.

	Animal matter.	Earthy matter.
African ivory . . .	51	50
Asiatic ivory . . .	38	50

The consumption of elephants' tusks in Sheffield, England, is about 45,000 *per annum;* and, allowing for the occasional finding of shed tusks, and those of elephants found dead, it is estimated that 20,000 are slaughtered yearly to supply this *city of cutlery.*

Ivory is rendered flexible by steeping in a solution of hydrochloric acid. This extracts the phosphate of lime and gives flexibility to the ivory, without impairing its form. Tubes and probes of this material have been made, and the partial hardness which occurs on drying may be removed by surrounding the piece with wet linen, or placing pellets of wet sponge in the cavities of the instrument.

Or immerse ivory in a solution of pure phosphoric acid, s. g. 1.130, until the opacity is removed; wash and partially dry. Will become hard when perfectly dry, but again becomes flexible when placed in hot water.

Another mode of softening ivory is to soak it for three or four days in a mixture of 3 ounces of spirit of niter and 15 ounces of spring-water, when it will be soft enough to obey the fingers. To color it in this state, dissolve the proper pigment in spirit of wine, then immerse the ivory and leave until sufficiently tinged, then give it the proper form. To harden it, wrap in a sheet of white paper and cover with dry, decrepitated common salt, and leave for twenty-four hours. To whiten ivory that has turned brown, slack some lime in water, decant, and boil your ivory in this till white. It is also bleached by sulphurous acid, by chloride of lime, or by soaking in water and exposure to the sun.

Ivory brought from Nineveh in a fragile and crumbling state was restored by Professor Owen to a rigid condition by boiling it in a solution of gelatine. The animal matter had decayed out of it, leaving the phosphate of lime ready to fall to pieces.

A veneer of ivory was exhibited at the World's Fair in London, 1851, 41 feet long and 14 inches wide. It was sawn from a block in a continuous ribbon, the block rotating and its axis gradually approaching the plane of motion of the saw.

Russia affords a large supply of tusks from the remains of an extinct variety of elephant which once roamed the now inhospitable shores of the Siberian rivers. These bones, though not essentially changed in condition, are called fossil ivory, from the circumstances of their deposit and discovery.

The fruit of *Phytelephas macrocarpa*, a species of Peruvian palm, is the vegetable ivory of commerce.

Ivory has always been considered a luxurious article in countries where it is not indigenous. The Assyrians carried on a great traffic in ivory. In an Assyrian obelisk in the British Museum, the captives or tribute-bearers are represented as carrying elephants' tusks. The Egyptian monuments show the tusks, apes, and peacocks carried to Sesostris; the same articles were also brought to Solomon by the navy of Tarshish some hundreds of years later. Diodorus Siculus states that the Ethiopians brought to Sesostris "ebony and gold, and the teeth of elephants." Pliny states that ivory was so plentiful on the borders of Ethiopia that it was used for fences, door-posts, and cattle-stalls.

In regard to its ancient uses, it seems to have been essentially a regal luxury. "All manner of vessels of ivory" are enumerated as among the furnishing of opulent Babylon. Hiram fashioned the great ivory throne of Solomon, and overlaid it with pure gold. Ivory was freely used in the chairs and couches of

Digitized by Google

Egypt, as the paintings in the tombs yet testify. Ahab's ivory house, 900 B. C., and the palace of Menelaus, described by Homer, were probably paneled with ivory, or the walls and pillars inlaid therewith. Ezekiel records that ivory was used to ornament the Phœnician galleys.

Beds inlaid or veneered with ivory were used by those who, as Amos says, "are at ease in Zion," "that lie upon beds of ivory and stretch themselves upon their couches."

Two hunting inscriptions, one of which principally records the elephant hunts of Ptolemy Philadelphus, were discovered and copied by Lepsius from the colossi of Aboo Simbel. Since ancient times elephants have withdrawn more to the south in Eastern Africa also. According to the testimony of Polybius, when African and Indian elephants encountered each other on fields of battle, the sight, the smell, and the cries of the larger and stronger Indian elephants drove the African ones to flight. The latter were never employed as war elephants in such large numbers as were used in Asiatic expeditions, where Khandragupta had assembled 9,000, the powerful king of the Prasii 6,000, and Akbar as many.

The Numidian Metellus had 142 elephants killed in the circus. In the games given by Pompey, 600 lions and 406 panthers were shown. Augustus sacrificed 3,500 wild beasts in the festivities which he gave to the people; and a tender husband laments that he could not celebrate the day of his wife's death by a sanguinary gladiatorial fight at Verona, because contrary winds detained in port the panthers which had been bought in Africa.

To come down to a later date, ivory chairs and furniture were among the spoils of Seringapatam when Tippoo yielded up the ghost, and the government of Mysore.

The "Elephant's Tower" at Futtehpoor Sikra, a favorite residence of Akbar, the most illustrious Asiatic ruler of modern times (1556–1605), is ninety feet high, and is studded with elephants' tusks from top to bottom. It is conjectured to have been erected over the remains of a favorite elephant. This Akbar (very great), properly JELAL-ED-DIN MOHAMMED, was truly royal, and "kept house" on a very extended scale. Bayard Taylor gives a good account of Futtehpoor, a red sandstone city, deserted but not destroyed. Akbar had a fancy for chess-playing within a checkered court-yard of his palace, with beardless epicenes and troops of girls, who strutted and trotted from point to point as the dice were thrown and the moves called. See CHESS.

I'vo-ry, Ar-ti-fi'ci-al. A compound of caoutchouc, sulphur, and some white ingredients, such as gypsum, sulphate of baryta, oxide of zinc, or pipeclay.

Pinson's: immerse a sheet of gelatine in alumina, dissolved in acetic acid. When fairly combined, take out, hang up to dry, and polish.

Welling's artificial ivory is composed of 10 ounces of white shellac, 4½ ounces acetate of lead, 8 ounces of ivory dust, and 5 ounces of camphor. The ingredients are reduced to powder, heated, and mixed, then pressed in heated molds into sheets or other desired forms. See PYROXYLINE.

Another: two pounds of pure india-rubber are dissolved in thirty-two pounds of chloroform, and the solution saturated with purified ammoniacal gas. The chloroform is then evaporated or distilled off at a temperature of 185° Fah. The residue is mixed with pulverized phosphate of lime or carbonate of zinc, pressed into molds and cooled. When the phosphate of lime is used, the resulting compound partakes in a great degree of the nature and composition of genuine ivory, for the phosphate replaces the lime, and the india-rubber takes the place of the gelatine.

Ivory dust mixed with albumen, rolled into sheets, dried, and polished.

Sulphate of baryta and albumen rolled into sheets.

Billiard-balls made of a mixture of paper pulp, sulphate of baryta, and gelatine, are said to be equal to those made of ivory.

Plaster of paris saturated with melted spermaceti.

The following United States patents bear upon this subject; the figures are day, month, year: —

Welling	4, 8, 1857.	Sceley	23, 6, 1868.
Held	4, 8, 1857.	Welling	5, 5, 1868.
Hackert	31, 5, 1864.	Gradenwitz	25, 5, 1869.
Dupper	1865.	Hyatt and Blake	4, 5, 1869.
Wheeler	14, 11, 1865.	Welling	20, 4, 1869.
Wurtz	1, 1, 1867.	Welling	27, 4, 1869.
Hackert	19, 2, 1867.	Welling	27, 4, 1869.
Starr	3, 3, 1868.	Hyatt	6, 4, 1869.
Starr and Welling	9, 6, 1868.	Hyatt	6, 4, 1869.
Hyatt	14, 4, 1868.	Hyatt	15, 6, 1869.
Gardner	7, 1, 1868.	Welling	17, 1, 1870.

I'vo-ry-black. A species of bone-black made by the calcination of ivory scraps, turnings, and sawdust. It is used as a pigment in the manufacture of paints and printers' ink.

I'vo-ry-pa'per. A superior article of pasteboard, with a finely prepared polished surface, used by artists.

Ainslie's process for making ivory-paper is as follows: —

Digest four ounces of clean parchment cuttings in water for four hours, and strain off the jelly. Digest again for a farther quantity. Keep these apart as Nos. 1 and 2. Saturate with No. 2 two sheets of drawing-paper, 15 × 17 inches, lay them together, and strain them over a smooth slate, pasting them on the back. Allow them to dry gradually. Wet three more sheets and add them to the former, one at a time. When dry, smooth with sand-paper; wet and add a perfectly clean sheet. Dry it and smooth with fine glass-paper. Heat one half-pint of size of No. 1, and stir into it three tablespoonfuls of plaster of paris; distribute it over the surface; dry; polish with glass-paper. Spread several coats of size No. 1 upon the surface, polishing each time with fine glass-paper. Plaster of paris, oxide of zinc, and carbonate of baryta give different tints.

I'vo-ry-saw. A thin saw stretched in a steel frame for sawing ivory from the solid. It has a blade $\frac{1}{10}$ inch thick, 1½ inch wide, and 15 to 30 inches long. The teeth, 5 or 6 to the inch. A frame-saw with a blade made of a fine watch-spring is suitable for the purpose.

I'vo-ry-tab'let. Small leaves of ivory, arranged in pocket-book form, for receiving memoranda.

Artificial ivory tablets for photography are made by mingling finely pulverized sulphate of baryta or heavy spar with gelatine or albumen, compressing the product into sheets, and drying it.

The laws of the twelve tables of Rome were originally written on oak, then transcribed on ivory tablets, and hung up *pro rostris;* after approval by the people, they were engraved on bronze. The opulent Romans used their slips of ivory, called *libri eborici* or *libri elephantini;* and Ulpian states it was common to write on such with black ink.

I'vo-ry-type. (*Photography.*) A kind of picture in which two finished photographs are taken, one light in color, made translucent by varnish, tinted on the back, and placed over a stronger picture, so as to give the effect of a photograph in natural colors. Also known as *Hellenotype.*

I'vo-ry, Veg'e-ta-ble. The nut of the *Phytelephas macrocarpa.*

Digitized by Google

J.

Jab. (*Nautical.*) To catch fish by prodding; said of fishing with a *gaff*.

Jabb. A peculiar fishing-net for catching the fry of fish.

Jack. A handy tool. A name applied to a convenient implement which answers in the place of another hand or of an assistant. It is frequently compounded with other words, the associated word expressing either its purpose, structure, or relation.

As a simple word it has meanings: —

1. A lifting instrument. See JACK-SCREW; WAGON-JACK; WHEEL-JACK; CAR-JACK; FENCE-JACK; RAIL-JACK; HYDROSTATIC JACK, and others in the list below.

2. An instrument for turning a roasting joint of meat. A *bottle-jack*, or a *smoke-jack*.

3. (*Knitting.*) The pivoted bar or lever in a knitting-machine, from whose end is suspended the sinker which forms the loop. A *beater*.

4. (*Spinning.*) A coarse bobbin and fly-frame, operating on the sliver from the carding-machine and passing the product to the fine roving-machine, or fitting it therefor.

5. (*Weaving.*) The *heck-box*; a grated frame for conducting the threads from the *bank* to the *warping-mill*.

6. (*Mining.*) A wooden wedge used in mining for assisting in the cleavage of strata. A *gad*.

7. A saw-horse or saw-buck. Two X-shaped frames united by a round or rundle.

8. A small flag. The *union* without the *fly*. See FLAG.

9. (*Metal-working.*) A form of *metal planing-machine* which has short, quick motions, and is used in shaping objects, planing seats for valves, faces for the same, etc.

10. (*Nautical.*) The cross-trees.

11. (*Music.*) Formerly the hammer or quill-carrier of a clavichord, virginal, harpsichord, or spinet, but now an intermediate piece which conveys to the hammer the motion imparted to the key.

The piano-movement jack, which imparts the motion of the key to the hammer, is the invention of Christofori of Florence, 1711. Rimbault's "Pianoforte," London, 1860. See PIANO-FORTE.

As a compound word, see under the following heads: —

Boot-jack.
Bottle-jack.
Builder's jack.
Carriage-jack.
Chimney-jack.
Claw-jack.
Crick.
Fence-jack.
Hand-screw.
Hoisting-jack.
Hydraulic jack.
Hydraulic lifting-jack (see HYDRAULIC PRESSES AND LIFTERS).
Hydrostatic jack.

Windlass-jack.
Window-jack.

Jack-arch. An arch of the thickness of one brick.

Jack-back. 1. A vessel below the brewery-copper which receives the infusion of malt and hops therefrom, and which has a perforated bottom to strain off the hops.

2. A tank or cistern which receives the cooled wort in a vinegar-factory.

Jack-block. (*Nautical.*) A block used in sending the top-gallant mast up and down.

Jack-boots. 1. Large, overall boots, reaching up the thigh; worn by fishermen.

2. Large boots with a front-piece coming above the knee; worn by cavalry-men, and sometimes by huntsmen.

Jack Cross-tree. (*Nautical.*) An iron cross-tree at the head of a top-gallant mast.

Jack'et. An enveloping or outer case of clothing, steam, water, or other substance.

1. A *steam-jacket* is a body of steam between an inner and outer cylinder or casing; its usual purpose is to warm or maintain the warmth of the contents of the inner cylinder. It was invented by Watt.

The steam space around an evaporating-pan to heat the contents.

Other jackets are of wood or other non-conducting material. Cylinders of steam-engines are sometimes covered with felt and an ornamental wooden casing to prevent radiation of heat. Steam-boilers, for the same purpose, are jacketed with felt on the upper part. *Cleading, deading, lagging.*

2. (*Nautical.*) *a.* A double or outer coat.

b. A casing for a steam-chimney where it passes through a deck.

3. A swimming garment with cork lining. A *cork-jacket*.

Jack-frame. (*Cotton-manufacture.*) A device, formerly in greater favor, for giving a twist to the roving as it was delivered by the drawing rollers.

In order to give a certain degree of cohesion to the sliver, the can into which it was received from the drawing rollers received a rapid rotation, imparted by the table on which it stood. See DOUBLING; ROVING.

Following this process was that of winding it upon bobbins, so as to be fed from thence to the spinning-frame.

The *jack-frame*, or *jack in the box*, was devised to twist and wind the sliver and form it into a roving on a bobbin *in the can*.

Digitized by Google

The twist is given to the sliver by the revolution of the can on its vertical axis; but instead of being coiled up within the can as usual (see DOUBLING), the roving was wound upon a bobbin *b* lying upon a carrier cylinder *c* made to revolve by wheel-work (not shown) at such a rate that its surface velocity corresponded to that of the delivering drawing roller. A guide-wire *g* moved backward and forward in front of the bobbin distributes the roving equally thereon. The *jack-frame* was superseded by the BOBBIN and FLY-FRAME (which see). The mode of rotating the bobbin survives in Mason's speeder.

Fig. 2708.

Jack-Frame.

Jack-head Pump. A form of lift-pumps for mines and deep borings, in which the delivery-pipe is secured to the cylinder by a goose-neck. See PLUNGER-PUMP.

Jack-in-a-bas'ket. (*Nautical.*) A basket on a pole marking a shoal. A beacon.

Jack-in-a-box. 1. A name conferred upon the *jack-frame*, a device for giving a twist to the drawn *sliver* and winding the same on a bobbin as it was received in the *roving* can. See JACK-FRAME.

2. *a.* A large, wooden, solid screw turning in a nut in a bridge-piece and rotated by means of a lever. It is a clumsy form of screw-press, used for various purposes.

b. A screw-jack for lifting and for stowing cargo.

Jack'knife. A horn-handled clasp-knife with a laniard, worn by seamen.

Jack-lad'der. (*Nautical.*) One with wooden steps and side ropes.

Jack-pin. (*Nautical.*) A belaying-pin in the fife-rail or elsewhere.

Jack-plane. (*Carpentry.*) The first and coarsest of the joiner's bench-planes; the others being the *trying*, *panel*, and *smooth* planes. It is about 18 inches long.

Jack-raft'er. (*Carpentry.*) One of the short rafters used in a *hip-roof*.

Jack-screw. A lifting implement which acts by the rotation of a screw in a threaded socket. In *A* the screw is double, the portion *a* turning in *b*, and the latter in the collar of the base *c*. The spanner *d* rotates the nut *e* and with it the screw *b*, which climbs out of *c* and at the same time projects *a*.

B is a railway-jack, moved by a lever (which is shown broken off), and acting by pawl and ratchet, either throughout a circle or by reciprocation where the position is confined.

C is a traversing-jack which moves the load along by a secondary screw *f* so that the standard *g* slips on the ways *h*.

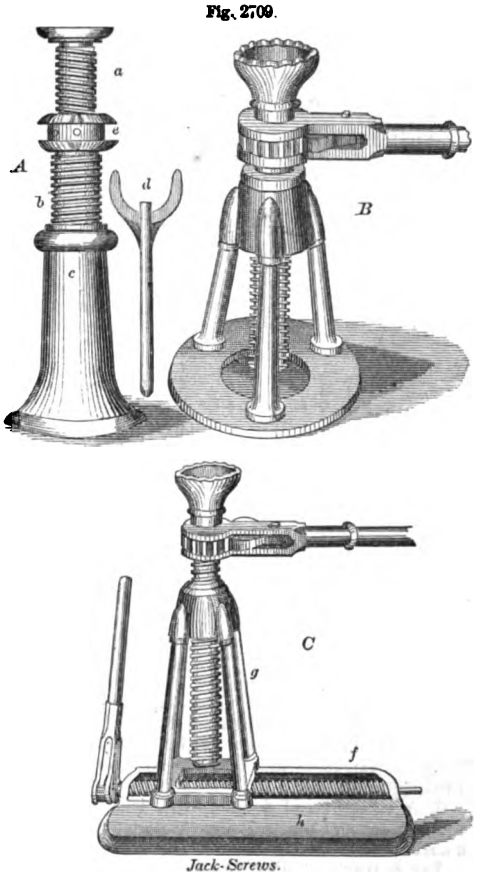
In another form the screw is rotated by bevel-wheel and pinion.

Jack-sink'er. (*Knitting-machine.*) A thin iron plate suspended from the end of the *jack*, and acting to depress the loop of thread between two needles. The jack-sinkers, alternate with *lead-sinkers*, the former being movable separately, but the latter are attached to a *sinker-bar*, and move together. See KNITTING-MACHINE.

Jack-staff. (*Nautical.*) A flag-staff on the bowsprit-cap for flying the jack.

Jack-stay. (*Nautical.*) A rib or plate with holes, or a rod running through eye-bolts, passing along the upper side of a yard, and to which the sail is bent.

Fig. 2709.



Jack-Screws.

Jack-tim'ber. (*Carpentry.*) A timber in a building which is shorter than the other timbers, being intercepted by another piece; as, —

A *studding* in a partition, which is intercepted by a brace or a window or door frame.

A *rafter* in a hip-roof, which meets the hip and is shorter than those which run to a full length and meet at the comb or ridge.

A *rib* in vaulting or groining, shorter than the main rib.

Ja'cob's Lad'der. (*Nautical.*) A rope ladder with wooden rounds.

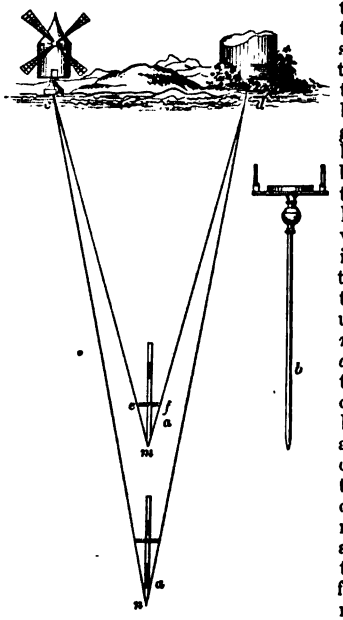
Ja'cob's Staff. 1. An instrument for taking altitudes, having a brass circle divided into four equal parts by two diametric lines. At each extremity is a perpendicular riglet over the lines, with a hole below each slit for discovering objects. The cross is mounted on a staff. A *cross-staff*.

2. (*Surveying.*) An instrument (*a*, Fig. 2710) used to measure distances and heights. It has a square rod, with a cross or cursor, which has a set screw to keep it in position on the rod when required. The rod is three or four feet in length, and divided into four or five equal parts. The cursor has a square socket and slips on the staff; its length is equal to one of the divisions of the staff. The instrument is mounted on a tripod when in use, the cursor being in the plane of the horizon when measuring distances, and vertical thereto when measuring hights.

The cursor is adjusted on the rod to the second

Digitized by Google

Fig. 2710



Jacob's Staff.

division, and the observation taken from such a position that the direction of the staff bisects the angle subtended by a line drawn between the two objects. Retire or advance with the instrument until from the station *m* the visual line from *m* passing to *c d* will touch the ends *e f* of the cursor. Place a picket at *m*. Slip the cursor on to the third division of the staff and retire till from a new station *n* the visual rays from thence will reach the same objects, *c d* touching *e f* as before. Drive a picket. The distance between the pickets is equal to the distance between the objects. This is but one illustration of its application. See Cresy's "Encyclopedia Civil Engineering," edition 1865, pp. 832–835.

3. A straight rod *b* shod with iron, and with a socket joint and pintle at the summit for supporting a surveyor's *circumferentor*.

Jac-o-net'. (*Fabric.*) A fine, close, white cotton goods, like cambric.

Jac'quard Loom. A loom for weaving figured goods. A chain of perforated cards is made to pass over a drum, and the strings by which the threads of the warp are raised pass over an edge with a wire or leaden weight of small diameter suspended from each. These weights, at each stroke of the loom, are presented to each successive card, and some of them are intercepted by the card while others pass though the holes therein, the latter thus determining which threads of the warp shall be raised. In this way the figure on the card determines the nature of the figure on the fabric.

Jacquard, the inventor, was a straw-hat manufacturer at Lyons. His attention was first directed toward mechanical inventions by a reward being offered for the production of a machine for making nets. He produced the machine, but did not claim the reward. The attention of Napoleon was called to his inventive genius, and he was sent for to ascertain if he could not improve on a loom belonging to the government. This was designed for weaving shawl patterns in imitation of cashmere, and its setting up and arrangement were very troublesome and expensive.

The great war minister Carnot is reported to have said to Jacquard, "Are you the man who can do what the Almighty cannot: tie a knot on a stretched string?" Jacquard, improving on the model of Vaucanson, produced the apparatus which bears his name, and was rewarded with a pension of 1,000 francs. This was afterwards increased to 6,000. He was also awarded a bronze medal at the French Exposition in 1801.

On returning to Lyons, he met with great opposition from the weavers there, who endeavored to forcibly suppress the invention. The "Conseil de Prudhommes," a board of master workmen in the various branches of trade, who are appointed to look after the manufacturing interests, adjust wages, and settle disputes between masters and workmen, ordered his machine to be broken up in the public place, and, according to Jacquard's own expression, "the iron sold for iron, the wood for wood, and he, the inventor, was delivered over to universal ignominy." The value of the invention was, however, soon appreciated elsewhere, and was finally recognized by the Lyonese themselves, to whom it has since proved of inestimable value.

Jag. A barb or dovetail which resists retraction.

Jag-bolt. One with a barbed shank.

Jag'ger. 1. (*Domestic.*) A small wheel mounted in a handle and used for crimping or ornamenting edges of pies, cakes, etc., or cutting them into ornamental shapes. A *jagging-iron*.

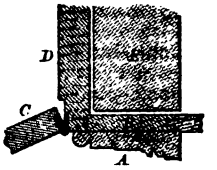
2. A toothed chisel.

Jag'ging-board. (*Metallurgy.*) An inclined board in a *buddle* or *frame* on which *slimes* of ore are deposited to be gradually washed by a current of water to the inclined bed where the slimes are sorted according to gravity. See BUDDLE; FRAMING.

Jal-ou-sie'. A *louvre* or *Venetian* shutter.

Jamb. 1. (*Architecture.*) The upright sides of an aperture, as a doorway, window, or fireplace, and supporting the lintel, entablature, or mantel.

Fig. 2711.



Jamb and Fittings.

The *jamb-linings* are the casing, and have a rabbet for the door to shut into.

Jamb-posts are framed into an aperture, and upon them the *linings* are attached.

Jamb-stones are employed in building sides of an aperture.

A, architrave.
B, plowed ground.
C, door.
D, rabbeted joint.
E, quarter.

2. (*Mining.*) A pillar of ore in a mine.

Jamb-lin'ing. (*Carpentry.*) The vertical boarding on the sides of a doorway.

Jamb-post. (*Carpentry.*) One of the uprights on the sides of a doorway or window.

Jamb-stone. (*Architecture.*) One of the stone pillars on the sides of a doorway or of a window.

Jam'da-ri. (*Fabric.*) A Dacca muslin woven with figures of flowers and other ornaments.

Jam-nut. An auxiliary nut screwed down upon another one to hold it. A *check-nut*, *lock-nut*, or *pinching-nut*. See NUT-LOCK.

Jam-weld. (*Forging.*) A weld in which the heated ends or edges of the parts are square butted against each other and welded.

Jank'er. (*Scotch.*) A long pole on two wheels, used in transporting logs.

Jan'tu. A water-raising device of great antiquity used in Bengal for land irrigation. It is a trough counterweighted by an extended arm and balanced across a bar. As the trough end descends it dips water, and, as it rises, the water runs towards the axis of vibration and escapes at a lateral orifice into a trough, which conducts it to the field. See GUTTER for a common device on this principle, excepting the counterweights. See also BAIL-SCOOP.

Ja'nus-cloth. A fabric having each side dressed,

Digitized by Google

and different colors on the respective sides. Such fabric is used for reversible garments.

Ja-pan'. 1. A hard, black varnish, obtained from the *Stagmaria verniciflua* of the East Indies.

2. An asphaltum varnish. See VARNISH.

Ja-pan'-earth. (*Tanning.*) Terra japonica, catechu, cutch. An astringent matter obtained from the *Areca catechu* and *Acacia catechu;* used in tanning.

Jap-a-nese' Silk. (*Fabric.*) A dress goods having a linen chain and silken weft.

Ja-pan'-ink. A writing-ink which has a dark, glossy color when dry. See INK.

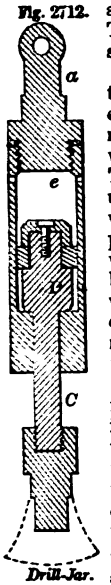
Ja-panned' Leath'er. Leather treated with several coats of Japan varnish and dried in a stove.

Ja-pan'ning. The art of coating wood, metal, or paper, with a thick coat of hard, brilliant, varnish. The art originated in Japan. *Japanning* involves the *baking* of the varnished article.

The Japanese employ a lacquer obtained from a tree by making incisions in the trunk and collecting the juice; this is at first like cream, but becomes black by exposure to the air. Their process is said to be as follows: After the juice has assumed a deep black color, finely pulverized charcoal is added to it. The lacquer is applied to an article in several successive coats, each being dried in the sun before the next is put on. It soon becomes extremely hard, and is polished with a smooth stone and water until it becomes as smooth as glass. On this surface ornaments and figures are traced with a brush dipped in a varnish of boiled oil and turpentine. Before this is quite dry, gold or silver leaf is laid on, and the whole afterward receives a finishing coat of varnish.

With us the work is first covered with a ground composed of anime (*Hymenæa courbaril*) varnish mixed with a pigment of the desired color; this is dried in a stove, after which three or four coats of varnish are applied. The varnishes employed are copal, anime, mastic, or seed lac. The latter gives the hardest surface, but is too dark for the more delicate grounds, and is therefore usually mixed with some other kind of varnish. Articles such as wood or *papier-maché*, which are too coarse, soft, or rough to receive the japanning immediately on their surfaces, are first covered with a priming composed of chalk or whiting. This is allowed to dry, and is then rubbed smooth.

Fig. 2712.



Drill-Jar.

Engravings or drawings are transferred to japan work in the following way: The engraving is printed or the drawing made on fine paper, previously prepared with a coating of isinglass or gum-water. This, when dry, is applied face downward upon the japan ground, which is covered with a thin coat of copal varnish; the paper is then moistened on the back with warm water, which loosens it so that it can be removed, leaving the print on the work. Or a print may be made on an elastic composition of glue, etc., which may be applied immediately on the japanned surface.

Jar. 1. (*Well-boring.*) A device used in boring by impact of the chisel, which is alternately lifted and dropped. As the rope attached to the piece *a* is lifted, the chisel-stock *C* slips until arrested by the enlarged portion *D*. When the piece *a* is dropped, by the sudden slacking of the rope, the chisel falls, and the portion *e* comes on top of the chisel-stock *D* to give it an effective blow.

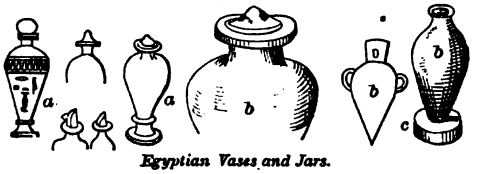
2. (*Domestic.*) A vessel of glass or earthenware for fruit, preserves, pickles, and various domestic uses.

The analogue of our modern fruit-jar is found in those of the ancient Egyptians, who seem to have been given to laying in great stores of provisions in this way. The paintings on the temples and tombs of Egypt show the storing of grain, wine, oil, poultry, and many other things, and the economy of their houses, pantries, and granaries shows that they made the most ample and profuse store of provisions. As an illustration, see Plate V. Vol. 2 of Wilkinson.

The jars of the accompanying cut have lids or stoppers, which are luted or rendered air-tight by liquid clay, pitch, gypsum, or mortar.

Some of the jars had flat bottoms *a*, and were set upon the cellar or store-room floor; and others, being

Fig. 2713.



Egyptian Vases and Jars.

pointed, were set in a stone ring, like the amphoræ *b b* and ring-base *c*. Late excavations on the site of Troy have exhumed ranks of enormous jars. See FRUIT-JAR.

Jas'per. 1. A silicious mineral of several varieties.

2. Marble of a greenish color, with small red spots. There is an antique jasper with small spots of black and white.

3. A kind of earthenware prepared from pounded spar.

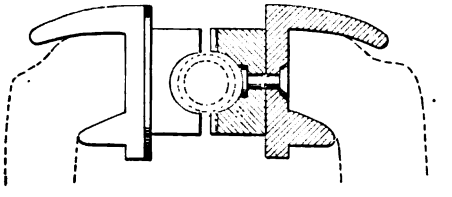
Jaunt'ing-car. An Irish vehicle having two seats, back to back, over the wheels, a well in the middle, and a seat for the driver in front.

Jave'lin. A hurling-spear, about 5½ feet long; it has a wooden shaft and an iron head. It is yet used in Europe in hunting the boar, and by many savage nations in ordinary hunting.

The *assegai* of the Caffre is a javelin of native iron.

Jaw. 1. (*Machinery.*) *a.* One of two opposing members capable of being moved towards and from

Fig. 2714.



Vise-Jaws for Round-Work.

one another; as the *jaws*, *cheek*, *chaps*, *chops*, or *mouth* of a vise or wrench.

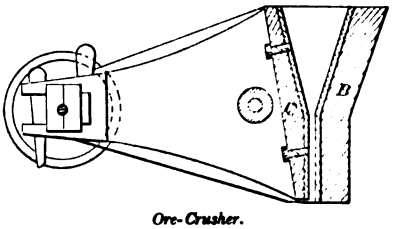
b. The cheeks of a stone or ore-crusher, one of which is moved relatively to the other, so as to break the material fed between them. In the example (Fig. 2715) *C* is the moving jaw, and *B* is a relatively stationary abutment. The movement of the jaw *E* is by an eccentric.

c. The opposed portions of a shearing-machine or punch, which, by moving past each other, cut the bar or sheet of metal placed between them.

2. (*Railway-cars.*) The guard-plates in which the axle-boxes of railway-cars play vertically as the springs yield and recoil. The *housings* or pedestals.

Digitized by Google

Fig. 2715.



Ore-Crusher.

3. (*Nautical.*) *a.* The forked end of a boom or gaff, which partially embraces the mast. The branches of the jaw are called *horns*, and are united by the *jaw-rope*.

b. The space in the shell of a tackle-block occupied by the sheave.

Jaw-lev'er. A veterinary instrument for opening the mouths of animals for the administration of medicine.

Jaw-tools. Tools having the capacity for grasping, as between jaws or fingers. See under the following heads : —

Animal-clutch.	Grapnalls.
Articulator.	Grapple.
Balance-vise.	Hand-vise.
Barrel-vise.	Humbug.
Bench-vise.	Ice-tongs.
Bloom-hook.	Inside-calipers.
Bolt-cutter.	Lasting-pinchers.
Bottling-pliers.	Lazy-tongs.
Bullet-mold.	Monkey-wrench.
Burling-irons.	Nail-clincher.
Burr-cutter.	Nippers.
Buttonhole-cutter.	Nut-cracker.
Calipers.	Pinchers.
Calking-vise.	Pinching-tongs.
Chimney-tongs.	Pipe-tongs.
Clamp.	Pipe-vise.
Clincher.	Pipe-wrench.
Clothes-pin.	Pliers.
Clothes-tongs.	Pruning-shears.
Clutch for hay-elevator.	Pucellas.
Coal-tongs.	Punch-pliers.
Compasses.	Rivet-cutter.
Costotome.	Rotary shears.
Crane's-bill.	Rounding-tool.
Crimping-tool.	Saddler's-pinchers.
Crow's-bill.	Saw-vise.
Crucible-tongs.	Scissors.
Cutting-nippers.	Shanks.
Dividers.	Shears.
Drawing-pliers.	Snipe.
Egg-tongs.	Spring-vise.
Elbow-tongs.	Suspending-clutch.
Entereotome.	Tongs.
Forceps.	Tube-cutter.
Gas-fitter's tongs.	Tweezers.
Glass-tongs.	Vise.
Glazier's-vise.	Wrench.

Jaw-wedge. A wedge to tighten the axle-box in the jaw or guard of a railway car-truck.

Jean. (*Fabric.*) *a.* A twilled, undressed cloth, having a cotton chain and woolen filling.

b. A twilled cotton goods, striped or white. *Satin jean* has a different twill, which gives it a smooth, glossy surface.

Jears. (*Nautical.*) A fourfold tackle by which a lower yard is *swayed* or *struck*. The upper block of this purchase usually hangs from the *trestle-trees*. *Jeers ; jeer-bits.*

Jed'ding-axe. A stone-mason's tool. It has one flat *face* for knocking off projecting angular points, and a pointed *peen* for reducing a surface to the required form. A *cavil*.

The *sax* or *zax* is a slate-worker's axe.

Jeg. A templet or gage, one of several, for verifying shapes of parts in gun and gun-stock making.

Jem'my. 1. (*Fabric.*) A species of Scotch woolen cloth.

2. A small crow-bar.

Jen'ny. (*Spinning.*) A form of spinning-machine invented by Jacob Hargreaves. A playful adaptation of the word *engine*. See SPINNING-JENNY.

Jet. 1. The *sprue* of a type, which is broken therefrom when the type is cold.

2. A solid, dry, black lignite, harder than asphalt and glossy in its fracture.

3. A spout of water in a fountain.

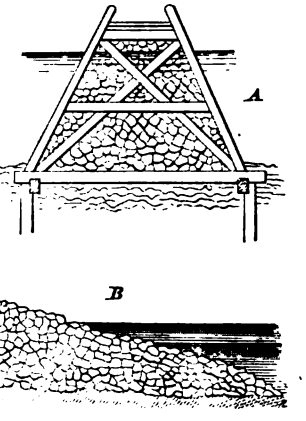
Jet-pump. A pump stated to have been originally contrived to empty the pits of submerged water-wheels. It acts by the pressure of a column of air passing through an annular throat ; or conversely, an annular jet around a central orifice. It has since been used in oil-wells. See EJECTOR.

Jette. The *starling* of a bridge. See STARLING.

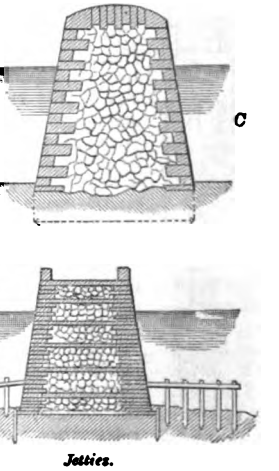
Jet'ting-out. (*Architecture.*) The projection of a corbel or molding beyond the general surface.

Jet'ty. 1. (*Hydraulic Engineering.*) *a.* A construction of wood, rubble-stone, or masonry projecting into the sea and serving as a wharf or *pier* for landing and shipping, or as a *mole* to protect a harbor.

Fig. 2716.



Although limited to no particular form, a very common construction of the jetty is a timber framing *A*, secured by piles or loaded with rubble. It is often built in the manner of a sea-wall ; having a double row of sheeting piles, the interval filled in with rubble or béton. The latter is excellent. The term *jetty* is also applied to expensive and solid erections of masonry, and to *hards* or landing-places for boats.



Jetties.

Telford's jetty *B* at the eastern arm

Digitized by Google

of Kingstown Harbor, Ireland, is an example of a jetty made of rubble, with a track and parapet of coursed masonry. The foreshore, in most works of this kind, is faced with pitched stones, that is, an outer layer in which the undressed stones are not laid at random, but deposited end on, beginning at the lower edge, and so caused to bind and become mutually sustaining.

Jetties of masonry (*C*) have usually *ashlar facings* and *heartings* of rubble or concrete. The walls filled in with béton will be nearly equal to a solid mass; in fact, béton itself makes a wall of such tenacity that its strength is equal to a homogeneous block. When the ashlar masonry is filled in with earth it requires a bond; when this is of masonry, the counterforts take the form of division-walls, which thus reduce the jetty to a series of compartments. The stones of these horizontal bonding courses should be cramped and joggled together, and the top carefully paved to prevent infiltration.

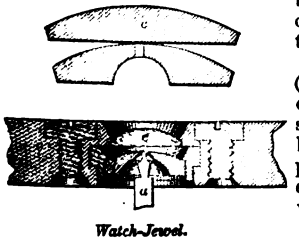
The southern jetty (*D*) of the port of Havre is exposed to violent storms and a powerful littoral current. It exemplifies the ashlar facing, horizontal bonding-walls, rubble filling, paving, parapets, aprons of piles and *pierre-perdue* to protect the foundations from the repercussion of the waves, all executed in a style which has provoked the admiration of those who have understandingly examined it.

In the course of the improvement of the mouths of the Rhine, the northern arm of the Maese is being widened, dredged, and extended into the sea by jetties of about 1,200 feet long and 1,000 yards apart. The mode of their construction is as follows: —

Long fascines are formed of brushwood and placed upon the shore near the site of the works; they are laid in courses, each course being at right angles or oblique to the previous one, until a thickness of about three feet has been obtained; strong stakes are then driven through the mass at frequent intervals, which project about 18 inches at the bottom, and 12 inches at the top. The stakes are then tied together with a willow binding. The work is made in sections measuring about 40 yards by 20 yards. When completed, it is floated to the site of the jetty, and sunk into its place by being evenly loaded with basalt stone, which is brought down the Rhine from quarries near Andernach. Piece after piece of this sort of work is added, until it covers the whole breadth of the base of the jetty for a portion of its length, after which another layer is formed in the same manner, and so on until the requisite hight and breadth of the jetty have been obtained, when a fresh length in advance is commenced. The projecting stakes soon take firm hold of the layers above and below them, the sand silts into the interstices of the brushwood, and in a few years forms an almost impenetrable mass, which, when consolidated, is covered with a paving of large basalt stones.

b. A structure round the piled foundation of a bridge pier.

Fig. 2717.



Watch-Jewel.

2. The part of a building which jets or juts over beyond the ground plan.

Jew'el. 1. (*Watchmaking.*) A crystal or precious stone forming a bearing for the pivot of an arbor; especially used in watches.

The balance jewel always has an *end-stone*, or cap *c*, the balance running on the end of its pivot in order that it may have the utmost freedom; the pivot being but the $\frac{1}{100}$ of an inch in diameter. Diamonds are sometimes used for end-stones, but rarely, if ever, for jewels, it being next to impossible to drill a hole sufficiently small in so hard a substance.

The invention of the process of drilling holes in rubies is attributed to M. Fazio, a native of Geneva, who introduced it into London in the year 1700.

Rubies are used as jewels in good watches. They are the hardest stone that can be drilled, but cheaper stones, such as crystals, garnets, etc., and even glass of hard quality, are often used.

The lower portion of Fig. 2717 represents on an enlarged scale the jeweled pivot-hole for the verge, or the axis of the balance of a marine chronometer. *a* is a hardened steel pivot, which is turned with a fine cylindrical neck, and is made convex at the end; the jewel consists of two stones; one *b*, usually sapphire or ruby, is convex above and concave beneath, of two different curvatures to thin it away in the middle, where the pivot-hole is drilled.

The other, *c*, called the *top-stone* or *end-stone*, is generally a ruby of plano-convex form, or else a diamond cut with facets. The flat side of this touches the end of the pivot.

The rubies or sapphires from which the jewels are made are sometimes split to the requisite thickness, but are commonly slit by a revolving iron disk charged with diamond-powder and oil. When sliced they are ground parallel on a flat plate of copper mounted on a lathe, into the face of which small fragments of diamond have been hammered, and afterwards polished on a similar plate with fine diamond-powder. They are afterwards turned circular and their edges beveled. In turning their faces to concave and convex form a fragment of diamond, mounted on a brass wire, is employed.

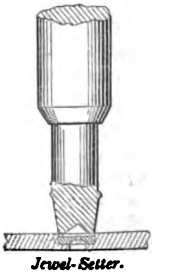
Drilling out the holes is also effected by a splinter of diamond mounted on a wire, this is usually accomplished at two operations, drilling into the two sides successively, after which the interior is polished with a fine steel wire and diamond-powder.

2. A precious stone; a gem. See GEM-CUTTING; SEAL; DIAMOND; STRASS; DOUBLET; BRILLIANT, etc.

The proficiency of the ancient Egyptians in the ornamental arts is well shown in collections of Egyptian jewelry. One ancient collection, dating back to 1900 B. C., is in the possession of the Sultan, and comprises ear-rings, necklaces, seal-rings, and amulets. The workmanship is of the most beautiful description. Many handsome specimens are also in the Museum of the Historical Society of New York. The museums of Europe are rich in specimens from Phœnician, Egyptian, Etruscan, Greek, and Roman sources.

Jew'el-block. (*Nautical.*) A block at the yard-arm of a ship, for the halyard of a studding-sail yard to pass through.

Fig. 2718.



Jewel-Setter.

Jew'el-ers'-red. Crocus.

Jew'el-set'ter. (*Watch.*) A circular steel cutter having a concave end with a circumferential angular edge, which slightly exceeds in circumference the bezel into which the jewel is to be fitted, and by which a circular burr of metal is pushed down upon the jewel.

Jew's-harp. 1. (*Nautical.*) The shackle by which a cable is bent to the anchor-ring.

Digitized by Google

2. (*Music.*) An instrument having a tongue vibrated by the finger and a frame held against the teeth for a sounding-board.

Jew's-harp Shack'le. A clevis and pin whereby the chain-cable is bent to the anchor.

Jews' pitch. Asphaltum.

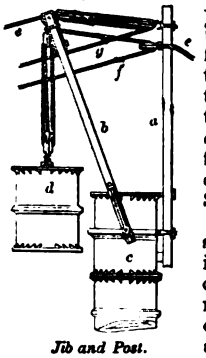
Jib. 1. (*Nautical.*) A large triangular sail set on a stay, forward of the fore stay-sail, between the fore-top mast-head and *jib-boom* in large vessels. It occupies a position between the mast-head and bowsprit in cutters, schooners, and small craft, and does not necessarily run on a stay.

Jibs are known by various names, according to position, etc., as *inner*-jib, *outer*-jib, *standing*-jib, *flying*-jib, *spindle*-jib, *storm*-jib, *jib-of-jibs*, etc.

A *jib-topsail* or *balloon-jib* extends towards the topmast head, and in cutter yachts is sometimes a very large sail.

2. (*Machinery.*) The extended arm of a crane; or that spar of a derrick which is stepped at the bottom and connected by tackle at the top to the vertical post. The post *a* is maintained vertical by guys, and the tackle affords a means for adjusting the inclination of the *jib b*, the *fall* being carried from the top of the post to a small *crab* on the ground, distinct from the larger crab which operates the hoisting-tackle. See CRANE; DERRICK.

Fig. 2719.



Jib and Post.

The jib of a derrick is stepped, and is adjustable in inclination. The jib of a crane is fast to the frame and rotates horizontally with it, or is journaled to the frame and is adjustable thereon. Sometimes vertically, for hight; always horizontally for sweep.

Fig. 2719 shows the mode adopted for hoisting the successive sections of the stand-pipe for the East London Water-Works. *a* is a jib-post, secured by a hoop to the standing portion of the pipe *c*; *b* is the jib; *d* is the section to be hoisted into place; *e e* are guy-ropes; *f g* the falls of the hoisting and the jib-tackles.

Jib-boom. (*Nautical.*) A movable spar running out beyond the bowsprit, for the purpose of affording a base to the jib in large vessels, and to the flying-jib in schooners and smaller craft.

Jib-door. A door made flush with the wall on both sides.

Jib-frame. (*Steam-engine.*) The upright frame at the sides of a marine-engine, connecting the cylinder, condenser, and the framing.

Jib-i'ron. (*Nautical.*) The traveler of the jib. An iron hoop fixed to the jib and sliding on the boom.

Jib-stay. (*Steam-engine.*) A portion of the stay-frame of a marine steam-engine. See JIB-FRAME.

Jig. 1. A handy tool. The name is applied to various devices, and in many trades small and simple machines are called jigs. In the armorer's set of tools we find cited, —

Drilling-jig.	Milling-jig.	Tapping-jig.
Filing-jig.	Shaving-jig.	

2. A trolling bait, consisting of a bright spoon and an attached hook. A ball of light metal on a hook.

Jig'ger. 1. (*Pottery.*) *a.* A horizontal table carrying a revolving mold, on which earthen vessels are shaped. A potters'-wheel; a *throwing* wheel.

b. A templet or former which is used in shaping the interior of a crucible or other vessel when the clay is upon the wheel. See Fig. 1536, *supra*. See also "Leçons de Céramique," Vol. II. p. 122 *et al.*; also "Feldspath Porcellan," Weimar, 1835, Figs. 79, 80, 82, Taf. VII.

2. (*Felting.*) To harden and condense a felted fabric by repeated quick blows from rods, or by a platen or platens having a rapid vibratory motion.

A machine for felting fiber by an intermittent rolling action upon the material, which lies upon a table, and is kept warm and wet.

3. (*Nautical.*) *a.* A double and single block-tackle, used for such jobs as holding on to the cable, abaft the capstan, as the cable is heaved in. Also used in hauling home the topsail sheet and other similar work.

b. A small tackle attached to the bight of another rope, to increase the purchase.

c. A supplementary sail rigged on a mast and boom, from the stern of a cutter or other vessel.

d. A small mast erected on the stern of a yawl.

e. A fishing-vessel whose rig corresponds to that of a cutter, excepting a small mizzen in the stern.

f. A weighted line with several hooks, set back to back, dropped into the water, and suddenly jerked upward to catch fish.

4. (*Coopering.*) A drawing-knife with a hollowing blade.

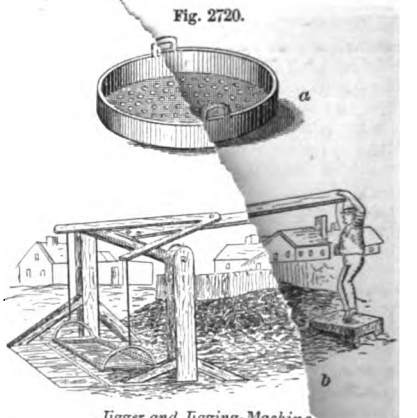
5. (*Leather.*) A machine for graining morocco leather, consisting of grooved boxwood rollers fitted in a frame suspended from the ceiling, and swung backward and forward like a pendulum.

6. (*Metallurgy.*) A riddle or sieve shaken vertically in water, to separate the contained ore into strata, according to weight and consequent richness.

The ancient Iberians washed gold-bearing earth in baskets in the time of Strabo.

The sieve *a* commonly consists of a hoop with handles, and a bottom of sheet-brass, finely perforated. It is used by striking it squarely upon the water, and giving it a semi-rotation simultaneously, to sort the pulverized ore according to gravity; the ore being lifted by the incoming water from below, and the

Fig. 2720.



Jigger and Jigging-Machine.

heavier portions settling first. The li… ter portions are scraped from the top, and the lowe… stratum removed for smelting or farther concentr… on.

The object is to keep the particles s… spended for a short time in water, so as to give the … avier portions a chance, by rapid subsidence, to a… nge the… selves as the lower strata in the sieve … finest portions pass through the meshes, settle … the vat, and are subsequently washed in a *buddle*.

Digitized by Google

Several applications of machinery to this purpose may be noticed.

In one (*b*) a heavy sieve is suspended from a lever, which has a horizontal roller for a rocking axis. The lever is worked by a man, who, by a saltatory motion, alternately lifts the *jigger* from the water and allows it to slap down again, raising the ore in the sieve, as has been stated. There are several other applications of machinery, perhaps as nearly allied to this as any other, and may here be noticed.

1. Submerged sieves agitated by steam or water power.

2. Submerged sieves in which the water is introduced in an active current from below.

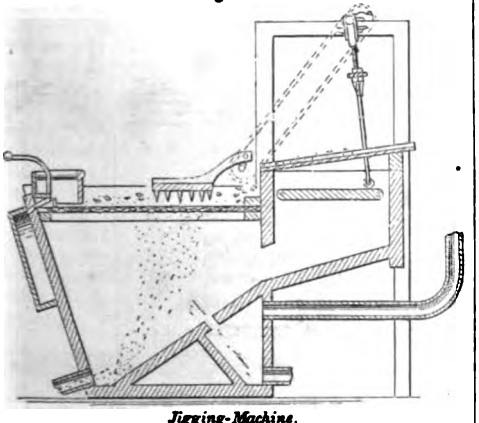
3. A box with a tight wooden floor, with an annular metallic trough pierced with holes, provided with movable sieves. In the middle of this circular system is a cylinder in which a piston plays, the effect being to alternately elevate and depress the level of water which passes through the sieves as it flows, and thus lifts the charges contained therein.

4. The jigging-sieve is attached to the end of a vertically reciprocating rod moved by a lever, which is oscillated by a wiper-wheel on a rotating shaft. The effect is similar to that just described, the layer of ore in the sieve being lifted as the sieve is slapped down into the water, the tendency of the heavier particles to settle first gradually sorting the charge into strata of varying weight and consequent richness.

Jig'ger-knife. A drawing-knife with a blade bent at one end and curved at the other, used by wheelwrights.

Jig'ging-ma-chine'. One in which the pulverized ore falls on to a sieve, where it is agitated by a rake, in water which is caused to pulsate by an intermittent plunger. The small and heavy particles fall through and are sorted by an opposing stream of water; the heavy and larger fall into a ragging-box, and the light are washed off.

Fig. 2721.

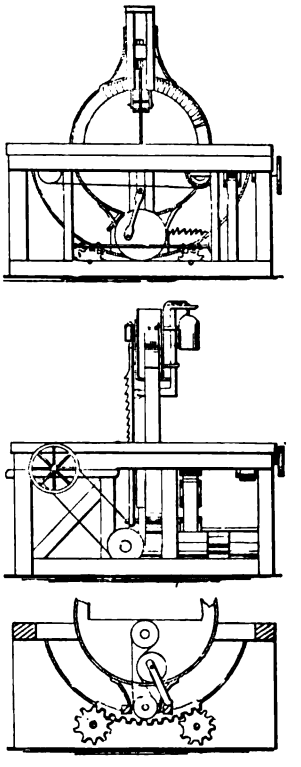


Jigging-Machine.

Jig-saw. A vertically reciprocating saw, moved by vibrating lever or crank-rod, as in Fig. 2722, in which the saw is arranged between two sliding head-blocks, to the upper one of which is attached an index to mark the bevel, a vernier plate being fixed to the circular iron-banded timber to which the blocks are secured by braces. It is moved by a segment of a cog-wheel under the carriage, gearing and working into pinions, and by a pulley-band over a drum.

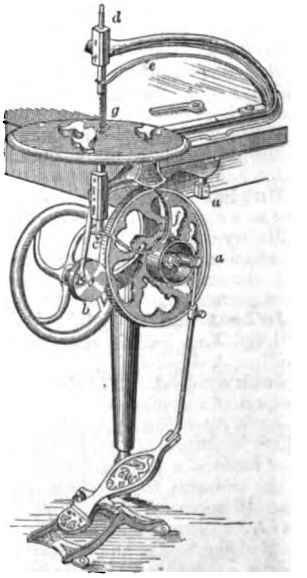
Fig. 2723 is a form of portable jig-saw, which is readily attached to a carpenter's bench or an ordinary table by means of a screw-clamp. The iron arm terminates in the guide *d*, in which works the spindle to which the upper end of the saw is attached, its lower extremity being similarly held in the guide underneath the table. A constant tension of the blade is maintained by the bent springs *e* and *f*. Motive-power is communicated from the treadle, which may be attached, at any convenient point on the floor, to a rod which forms a sleave for a smaller rod, which is connected with the crank of the large wheel *a*. The object of making the rod in two portions is that it may be adjusted to suit any hight of table, and afterward held in position by the set screw. Around the circumference of the wheel *a* is placed a covering of leather, by the friction of which the pulley *b* and the fly-wheel connected therewith are actuated. By means of the pitman, as shown, motion is transmitted to the saw. *g* is an adjustable metallic foot, designed for holding the work in place while being operated upon.

Fig. 2722.



Jig-Saw.

Fig. 2723.



Portable Jig-Saw.

Jim-crow. 1. An implement for bending or straightening rails.

In the examples, *A* is a screw machine, in which the rail lies upon the hooked feet.

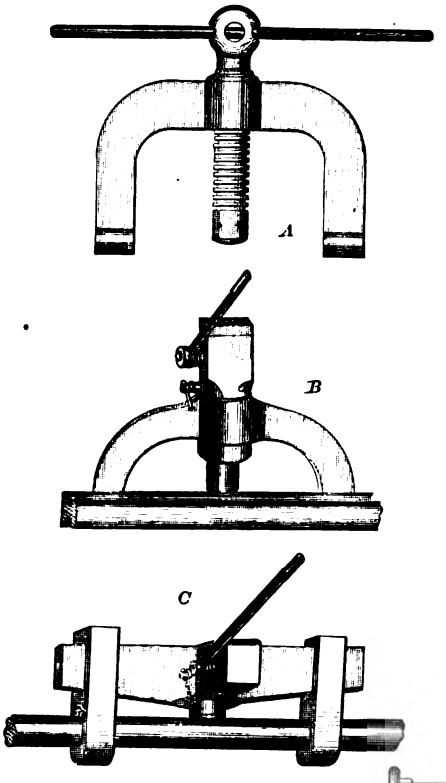
B C are hydraulic jim-crows with different modes of presentation, the upper one being a *rail-bender*, and the lower one (*C*) a shaft-straightener, and

Digitized by Google

may be used on a rod in a lathe. The jack swivels round in the frame so that the handle may be worked in any direction.

2. The *jim-crow* planing-machine is furnished with a reversing tool, to plane both ways, and named from its peculiar motion, as the tool is able to "wheel about and turn about." The table is moved endways by a quick-threaded screw, which allows the driving motion to be placed at the end.

Fig. 2724.



Jim-Crow.

Jim'my. A short crow-bar.

Jin'gal. A large musket used as a wall-piece in China and India.

Jin'glet. A ball within a spherical bell, which acts as a clapper.

Jin'ny-road. (*Mining.*) An inclined road in a coal-mine, on which loaded cars descend by gravity and elevate empty ones. Also known locally in some parts of England as a *jig-brow.*

Jo'bent-nail. (*Locksmithing.*) A thick-headed nail (*cf.* Eng. *jobber-nowl;* a blockhead; a numskull). A *dog-nail.*

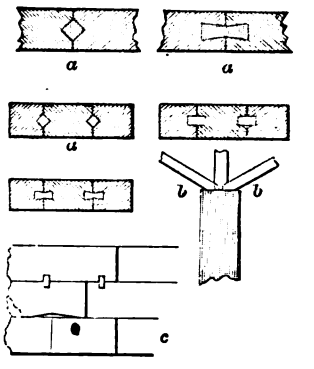
Jock'ey-pad. (*Saddlery.*) A knee-pad on the forepart of a saddle.

Jock'ey-stick. A stick five or six feet long, which is connected at one end to the hame of the *near* horse of a pair, and at the other end to the bit of the off-horse, to keep him at a distance. Used in connection with a single line, the favorite mode of driving a team in most parts of the West, many parts of the South, and worthy of adoption by all.

Jog. (*Machinery.*) A square notch.

Jog'gle. 1. (*Masonry.*) A joint-piece or *dowel-pin a a* let into the adjacent faces of two stones to preserve them in proper relative position. It may vary in form, and may approach in its shape either the DOWEL or CRAMP (which see).

Fig. 2725.



Joggles.

The stones of the Parthenon at Athens were united by oak joggles.

2. (*Architecture.*) In *pl.* Shoulders *b* on a truss-post, which support the lower ends of *struts* or *braces.*

Jog'gle-beam. (*Carpentry.*) A built beam, the parts of which are joggled together.

Jog'gle-joint. (*Masonry.*) A mode of uniting the stones of ashlar masonry. (*a a*, Fig. 2725.)

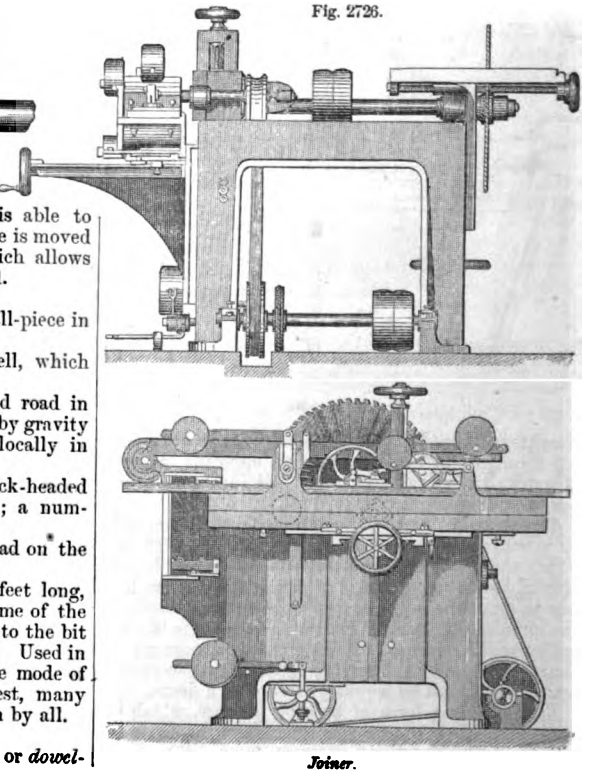
Jog'gle-piece. (*Carpentry.*) The upright member in the middle of a truss. A *king-post.*

Jog'gle-post. (*Carpentry.*) A post having shoulders to receive the feet of struts. See *b*, Fig. 2725; also KING-POST.

Jog'gle-truss. (*Carpentry.*) A hanging-post truss with only one post.

Jog'gle-work. (*Masonry.*) Work in which the courses are secured by *joggles*, as at *c*, Fig. 2725, so as to prevent their slipping on each other; as the courses of an abutment under the thrust of an arch.

Fig. 2726.



Joiner.

Digitized by Google

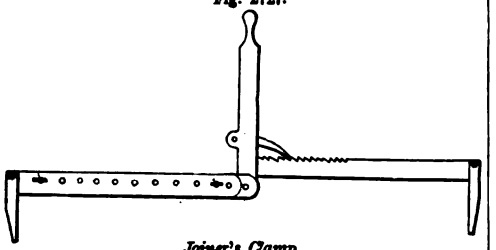
Join'er. A wood-working machine for doing various kinds of work, such as sawing, planing, and thicknessing, mortising, tenoning (single or double), cross-cutting and squaring-up, grooving, tongueing, rabbeting, mitering, molding and beading, chamfering, wedge-cutting, boring, and a great variety of other operations.

Attachable parts adapt the machine for certain duties, such as ripping out or for tenoning, for instance; the illustrations show it as adapted for cross-cutting and for planing or molding.

Join'er's-chis'el. A thin-bladed paring chisel.

Join'er's-clamp. A carpenter's appliance used in gluing up doors and other wide objects; the purpose of the arrangement in the example is to adapt it to fold into a small compass when not in use. See also CARPENTER'S-CLAMP.

Fig. 2727.



Joiner's Clamp.

Join'er's-gage. A scribing tool to make a mark on a board parallel to the edge of the latter.

Join'er's-plane. A bench-plane for facing and matching boards.

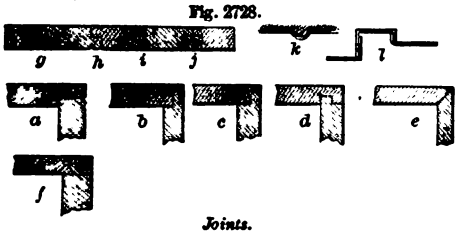
Join'er's Tools. See WOOD-WORKING TOOLS AND MACHINES.

Join'er-y. As distinguished from *carpentry*, the art of framing the finishing work of houses; doors, windows, shutters, blinds, cupboards; hand-railing of stairs, balconies, and galleries; mantel-pieces (if of wood), the construction of permanent fittings, and the covering of all rough timber.

The carpenter is supposed to use the axe, adze, chisel, and saw, and has to make and place the wall-plates, joists, and other floor-timbers, floors, staircase, the woodwork of the roofs, wooden partitions, and those portions of the frames of windows, doors, and skylights which are built into place.

Joint. A junction or mode of joining parts in a structure.

Fig. 2728.



Joints.

1. (*Carpentry.*) A mode of securing together the meeting edges of wooden structures.

The *straight* joint is where the edges make a butt-joint, being planed straight.

a, the bead conceals the joint.

b, may be nailed from both edges, and has a *jog* to prevent slipping.

c, employed for pilasters; it has interlocking jogs, which give a positive hold.

d, employed for skirtings, dadoes, backs, and back linings of windows, doors, jambs, and internal angle-finishing.

e, miter-joint.

f, dovetail-joint.

g, square joint.

h, rabbet-joint, with beads.

i, tongue and groove joint.

j, feather-joint.

Other joints are known by some peculiarity or finish or application, as: *Bracket*, *chamfered*, *covering*, *diamond*, *frontal*, *plain*, *side*, *suspended joints*.

To *joint* is to plane straight the edges of boards.

2. (*Plumbing.*) The sheets of sheet-metal roofing are joined by a *drip-joint k* or a *flashing-joint l* in cases where they are not soldered. The drip is used when the joint is *with* the *current*, and serves as a conductor for water. The *flashing* is a cap strip where the edges of the sheets meet on a projecting ridge. See also ANGLE-JOINT.

A *flush* joint or jump joint is a *butt*-joint covered with a plate on the inner side, called the *butt-plate*.

In a *lap*-joint the pieces overlap each other.

3. (*Masonry.*) The *face-joints* of voussoirs are those which appear on the face of the arch.

The *vertical* joint is between stones of the same course.

The horizontal joint is between courses.

The *coursing-joint* is the joint between the courses of voussoirs.

The *heading-joint* is that between two voussoirs in the same course.

The *flush-joint* is filled up to the face by pointing with mortar.

4. (*Bookbinding.*) The lateral projection of the back to correspond to or cover the thickness of the sides.

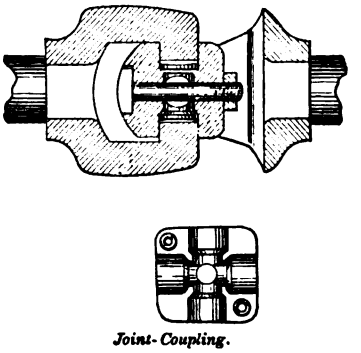
Joint-chair. (*Railroad.*) A railway chair which supports the ends of abutting rails.

Joint-coup'ling. A form of universal joint for

Fig. 2729.

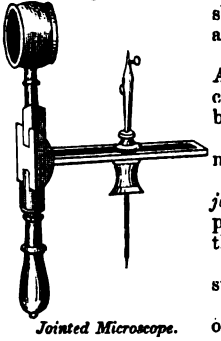


Joint-Coupling.

coupling sections of shafting. In the example, the pivoting points enter recesses cast in the clamping-iron, which is made in two parts, held together by a bolt. See also JOINT, for list of varieties.

Joint'ed-mi'cro-scope. A pocket microscope in which the handle and lens-holder shut down against the slide on which the object pliers are adjustable.

Fig. 2730.



Jointed Microscope.

Join'ter. (*Masonry.*) *a.* A tool for filling the mortar cracks between courses of bricks. A *pointing* tool.

b. A tool for marking the mortar-joints.

2. (*Coopering.*) The *stave jointer* is a large stationary plane on which the edges of the staves are worked.

The *heading jointer* has a straight-edged bit.

The *backing* or *side jointer*, otherwise called the *over-shave*, has a concave-edged bit, and is used for dressing the backs of staves.

The *inshave* has a convex-edged bit, and is used for dressing the inner faces of staves.

3. A bent strip of iron inserted into a wall to strengthen the joint.

Joint'er-plane. (*Coopering.*) A plane five or six feet long, its lower end resting upon the ground, and its upper end supported upon a prop, the inclined sole being presented upward for the staves, which are jointed thereon.

The Hindoos and Chinese bore a hole through the front of a plane for a stick whereby a boy assists by pulling the plane across or along the work. When the plane is very large, the Chinese place it at an angle, resting one end on the ground, in the manner of our cooper's *jointer*.

Joint-fas'ten-ing. (*Railway.*) A fish-bar or other means of locking together the adjacent ends of two railway rails.

Joint-file. A small file without taper, and circular in its cross-section. It is used for dressing out the holes for the joint-wire in snuff-boxes, etc., and in preparing the apertures for the pintles of hinges.

Joint-hinge. A strap-hinge. See HINGE.

Joint'ing-plane. (*Joinery.*) A plane with a long stock, used to true the edges of boards or staves which are to be accurately fitted together. It is 2 feet 6 inches long, and the work is called *shooting the joints.*

Joint'ing-rule. (*Bricklaying.*) A straight rule about six feet long, used by bricklayers in marking with white paint along each joint of the brick-work. Otherwise called *penciling*, and designed to render the joint conspicuous.

Joint-pipe. (*Gas-apparatus.*) A short section of pipe, forming a connection between two lengths, and usually having threaded sockets into which the parts are screwed.

Joint-pli'ers. A pliers adapted for securing the joints of compasses and similar instruments; also one by which the hinging of watch-cases is assisted.

Joint-saw. A saw with a curved working face, used in making the joints of compasses and other similar work.

Fig. 2731.

Joint-Saw.

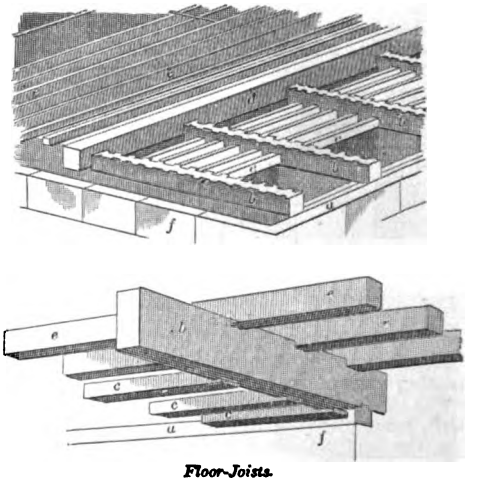
Joint-stool. A block holding up the ends of parts which belong in apposition, as railway rails, ways of vessels, etc.

Joint-wire. (*Watchmaking.*) The tubular wire, sections of which form the joints of watch-cases, lockets, etc.; a piece is hard soldered to each leaf, and a solid wire runs through to form the pintle. It is drawn upon a piece of steel wire, one end being tapered off with a file, so that the tube and wire are grasped together by the dogs and drawn after the manner of a solid wire.

Joist. (*Carpentry.*) A horizontal timber supporting a floor or ceiling, one or both.

Single flooring is formed with joists reaching from wall to wall, where they rest on *plates a* of timber built into the brick-work. The floor-boards are nailed on the upper edges of the joists, whose lower edges receive the lathing and plastering of the ceil-

Fig. 2732



Floor-Joists.

ings. Double floors are constructed with stout *binding joists b b*, a few feet apart, reaching from wall to wall, and supporting *ceiling joists c c* which carry

Digitized by Google

the ceiling, and *bridging joists c c* on which are nailed the floor boards.

When the main timbers of the floor are girders *d* which rest on the wall plates and support the *binding joists b b*, the floor is called a *framed floor*. The binding joists *b b* support the bridging joists *e e* and ceiling joists *c c* as before.

The *trimming* joists are short joists into which trimmers are mortised. Trimmers are pieces around a fire-hearth or a hatchway, where the continuity of the joists is broken.

The strength of joists, of equal thickness, is as the square of the height. A joist 4 × 6 has one quarter the strength of a joist 4 × 12. The latter is only twice as large.

Timber is weakened by sawing. A floor of 16 feet bearing, supported by 12 joists 8 inches square, 1 foot apart, is stronger than a similar floor of 24 joists, 8 × 4, placed edgeways, 6 inches apart. The quantity of timber is the same in both cases.

Jol'ly-boat. (Dutch *jol*; Danish *jolle*; a yawl.) A small boat used for the general miscellaneous work of a ship, such as bringing off marketing, etc.

A boat of this kind attached to United States vessels of war is called a *dingy*. It is clinker-built, from 16 to 20 feet long, with a beam from .33 to .29 of its length.

Jour'nal. (*Machinery.*) That portion of a shaft which rests in the bearings.

Jour'nal-bear'ing. (*Machinery.*) The support of a shaft or axle, generally boxes or brasses in a *pillow-block*.

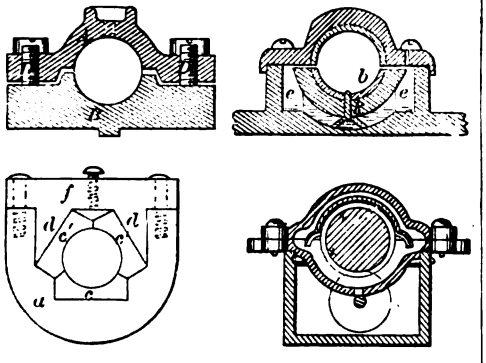
Fig. 2733 shows four varieties of journal-bearings for machinery.

In one *A* is the cap, *B* the pillow; *D D* are screws with set nuts for adjustment.

In another, the lower half *b* of the box rests in an oil reservoir *c*, from which the lubricant is led up by wicking *k*.

In the lower figure to the left, the bearing is made in three parts, *c c' c'*, movable by means of the wedge-

Fig 2733.



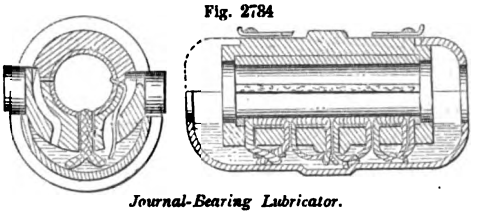
Journal-Bearings.

faces *d d* of the block *f* towards a common center to compensate for wear.

The right-hand figure below shows a shield above the journal to prevent the oil from being thrown through the joint between the two parts of the box.

Fig. 2734 shows a removable oil-reservoir, which can be detached without disturbance to the journal-box. The ends extend beyond the box, with caps to fit over such projections. An oil passage leads to the top of the box, for the conveyance of oil to the top of the box by means of a capillary substance,

Fig. 2734



Journal-Bearing Lubricator.

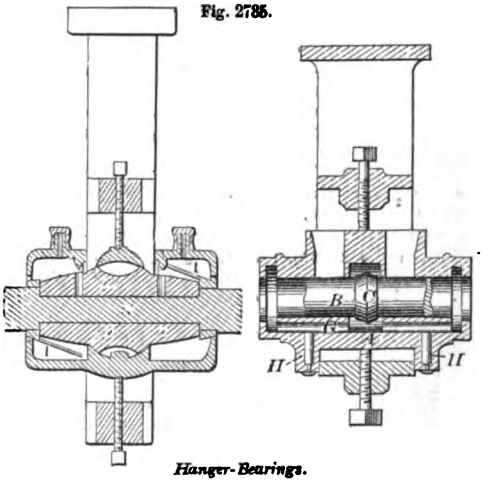
and a like passage on the other side of the box conducts back to the reservoir any surplus oil carried over by means of rapid motion.

Fig. 2735 shows two forms of journal-bearings in suspended hangers.

In the one to the left, the box is surrounded by a shell whose lower portion contains the oil which is raised by inclined wires in the shoulders of the shaft. The oil is carried up to the points which depend from the upper portion of the shell, and it then drops into the oil-holes of the box.

In the other view, the oil is carried up by the col-

Fig. 2735.



Hanger-Bearings.

lar *C*, distributes right and left, and returns by the longitudinal channels *G*. *H H* are sediment-boxes.

Fig. 2736 shows a number of bearings for axles.

Above, to the left, is one in which the axle-arm *F* rests on a wheel *D* which revolves in the oil-reservoir.

To the right of this figure is one with anti-friction rollers around the shaft; these are prevented from shifting endways by the circular flanges *F* on the axle and in the box which project within the peripheral grooves in the rollers *D*.

The circular system of anti-friction wheels for a journal-bearing is described in Tate's English patent, 1802.

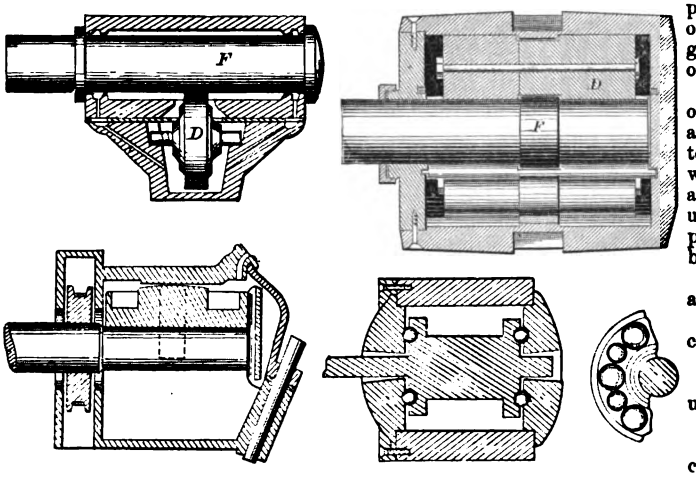
Below this figure is one in which the anti-friction balls are used. The casing has annular grooves in which balls of different diameters are placed alternately, so that the large balls will all turn in one direction, and the small balls will keep the large ones in position.

To the left, below, is a view of a railway car axle and box. See CAR AXLE-BOX.

Fig. 2737 shows a journal-bearing for a vertical shaft, with journal-box *a* in one piece. The spindle *b* is inserted from below, and coupled by a screw coupling or otherwise. The bolt above affords a

Digitized by Google

Fig. 2736.



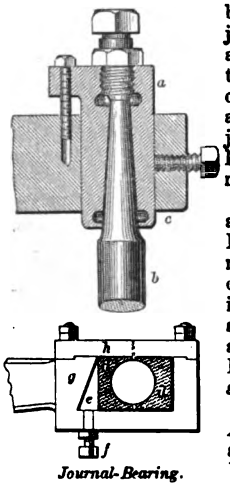
Bearings of Journals of Axles.

bearing for the end of the spindle, and the box has a receptacle for lubricant. Other lubricating chambers may be provided, as shown at *c*.

The lower portion of Fig. 2737 shows an adjustable box consisting of two portions *d d*, inside the strap *h* of a connecting rod.

The lubricity of oils or their comparative fitness for the lubrication of bearings and packing-boxes may be ascertained by a machine which determines the amount of frictional motion that is necessary to produce a given temperature.

Fig. 2737.



Journal-Bearing.

Girard's *palier glissant* employs water to act, first, by its pressure, to lift the journal to be lubricated; and, secondly, by its fluidity to form a liquid bed or cushion between the journal and its box, on which the journal may rest in its revolution without touching the metal of the box at all.

Water-bearing for steps and shafts is described in Bramah's English planing-machine patent, 1802. He describes it as a liquid bearing for steps of vertical shafts, and makes it adjustable by pumping in liquid. Known also as *palier glissant; hydraulic pivot.*

Babbitt's Anti-attrition Metal. Melt 4 lbs. copper; add, by degrees, 12 lbs. best banca tin, 8 lbs. regulus of antimony, and 12 lbs. more of tin. After 4 or 5 lbs. tin have been added, reduce the heat to a dull red, then add the remainder of the metal as above.

This composition is termed *hardening;* for lining, take 1 lb. of this *hardening*, melt with it 2 lbs. banca tin, which produces the lining metal for use. Hence, the proportions for lining metal are 4 lbs. of copper, 8 of regulus of antimony, and 96 of tin. See ALLOY.

Devlan's compositions for lining journal-boxes are various combinations of vegetable fiber, graphite, steatite, gum, bitumen; or paper pulp and silicate of soda or potash; or vegetable fiber, graphite, steatite, and silicate of an alkali.

Metaline is a material formed of metals, oxides of metals, and organic matter, reduced to powder, compounded with wax, gums, or fatty matters, and subjected to heavy pressure, so as to form solids of proper shape to form boxes and bearings for shafts or axles.

The following compositions are stated: —

Lignum vitæ and spermaceti.

Ivory-dust and spermaceti.

Tin and petroleum residuum.

Zinc and caoutchouc.

Plastic bronze and caoutchouc.

Type-metal and caoutchouc.

Anthracite and tallow.

Oxide of tin and beeswax.

Jour'nal-box. The carrier of a journal. See JOURNAL-BEARING; AXLE-BOX; CAR AXLE-BOX.

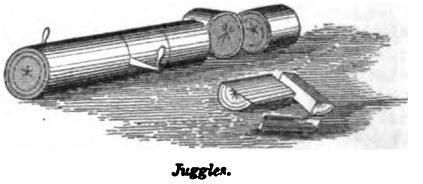
Jour'nal-box Met'al. See BABBITT-METAL; ALLOY.

Jour'ney. A corruption from JOURNAL (which see).

Juc'ten. A name by which *Russia leather* is known. *Juften.* See RUSSIA LEATHER.

Jug'gle. A block of timber cut to a length, either *in the round* or split.

Fig. 2738.



Juggles.

Jump. (*Forging.*) *a.* To upset by endwise blows, which contract the object in length, but thicken and spread it laterally. Applied to *jumpers*, tamping bars, axes, etc. See UPSETTING.

b. To attach by a *butt-weld*, in contradistinction to a *lap-weld.*

A transverse piece attached by welding is said to be *jumped on.* If formed from a portion of the rest, it is said to be *headed on.*

c. A gun-barrel made of a ribbon of iron, or laminated iron and steel, coiled around a mandrel at a red heat, then raised to a welding heat and placed on a cylindrical rod, which is struck heavily and vertically on the ground, is said to be *jumped.* The effect is to cause the edges of the ribbon to unite, a junction which is completed by the hammer on an anvil, the mandrel retaining its position. Such barrels are said to be *twisted.* The *twist* is *stub, wire,* or *Damascus,* according to the mode of manufacture of the ribbon. See TWIST; GUN-BARREL.

2. (*Mining.*) A fault or dislocation of a vein or lode.

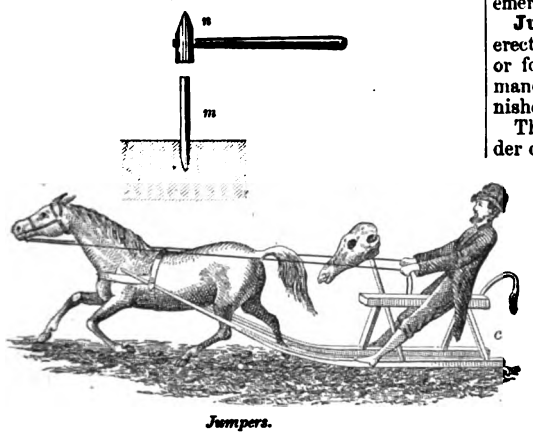
Jump'er. 1. (*Quarrying.*) *a.* A quarryman's boring-tool. A rod of steel, or pointed with steel, which breaks the rock by being alternately jumped

Digitized by Google

up and down to form a hole for blasting or for an artesian well.

b. A steel-faced chisel *m* held by one man while another strikes it with a hammer *n*. Used in drilling holes in rock for blasting or splitting.

Fig. 2739.



Jumpers.

2. A cheaply formed sled *c*, in which supple pieces of wood form the shafts and runners, and support a box or trestle in or on which the person rides.

3. (*Horology.*) *a.* A spring used in repeating-clocks to assist the motion of the star-wheel.

b. A species of click in the repeating-watch, preventing the motion of a wheel in either direction.

4. (*Planing.*) A plow-bit or machine-jointer, having an intermediate bearing upon the board.

5. (*Husbandry.*) A plow having an upturned cutter in front of its share, and which, going below the share, prevents its being caught on roots, etc.

Jump-joint. 1. A butt-joint.

2. A *flush*-joint, in which the plates or planking make a smooth face. In shipbuilding it is equivalent to *carvel*-build.

Jump-seat. (*Vehicle.*) A kind of open buggy which has a shifting seat or seats. For instance, it may be arranged as a double or single seat vehicle. In the former case, the main seat is moved over backwardly, and the extra seat brought up in front. As a single-seat vehicle, the main seat is thrown into a central position, the extra seat being placed below the other one.

Junc'tion-plate. (*Boiler-making.*) A welt or break-joint plate riveted over the edges of boiler-plates, which make a butt-joint.

Junc'tion-rails. (*Railroad-engineering.*) Switch rails which connect tracks.

Junk. 1. (*Vessel.*) (Dutch, *jonk*, perhaps from Chinese *yong*, the sea.) A vessel employed by the Chinese, Japanese, and Malays in navigating their seas.

It is the largest kind of Chinese vessel. It has no prominent stem or keel. The bow on deck is square, and the anchors are on each side of the bow. The stern is full, the rudder suspended, and at sea is lowered beneath the depth of the bottom of the vessel. The immense masts are in one piece, the lug-sails are sometimes of matting.

2. Old cable and rope cut into lengths, to make *mats*, *swabs*, *gaskets*, *sinnet*, *oakum*, etc.

Junk-ring. (*Steam-engine.*) *a.* A metallic ring which is screwed down upon and confines the hemp packing of a piston.

b. A steam-tight packing around the piston of a steam-engine.

Junk-wad. (*Ordnance.*) A wad made of oakum bound with spun-yarn, and filling the bore of the gun. It is placed between the charge and the ball.

Ju'ry. (*Nautical.*) A term applied to temporary structures, such as masts, rudders, etc., used in an emergency.

Ju'ry-mast. (*Nautical.*) A temporary mast erected in place of one that has been carried away; or for navigating a vessel to a place where the permanent equipment of masting and rigging is furnished.

The temporary rig is termed *jury-rigged;* a rudder of the same character, a *jury-rudder.*

Jus'ti-fi-ca'tion. 1. (*Printing.*) The adjustment of distance between the letters in the words and the words in a line, so as to avoid any glaring disproportion, and make them fill the measure.

2. (*Bookbinding.*) Attention to keeping the matter of pages in exact register or correspondence, to secure even margins.

Jute. (*Fiber.*) The fiber of *Cochorus capsularis* and *C. olitorius*, which is used in India for making gunny-bags, matting, rope, and other coarse fabrics.

In the manufacture of fabric from this article, the jute, after being taken from the bale, is sprinkled with oil and water, spread out on a table for a day or two, and then passed between rollers to render the fibers soft and pliable. It is next passed between toothed rollers, which bring the fibers nearly parallel, arranging them into a species of ribbon or sliver, which is again passed between two rollers with finer teeth than the preceding pair. These two machines are called the *breaker-card* and the *finisher-card.* The slivers thus formed are received into cans and subjected to the action of the *drawing-frame*, which is similar in its operation to that employed in the cotton manufacture, drawing out, narrowing, and thinning the slivers. The sliver is then slightly twisted and wound upon bobbins by the *roving-machine*, and afterwards spun by a *throstle;* the throstles making from 3,000 to 4,000 revolutions per minute.

The finished yarn for the warp is wound on large bobbins in the *winding-machine*, and placed on the loom beam by the *beaming-machine;* the weft yarn is wound on the pirns of the shuttles by the *pirning-machine.* The loom and shuttle are larger and stronger than those employed for weaving cotton, the fabrics made being generally coarser.

The finest jute yarns bear the lowest numbers, while in cotton the reverse is the case.

Jute-twine is sized with glue-water, starch, tallow, and China clay.

Crossley's patent floor-covering has a foundation of coarse jute coated with a layer of wool, and the two united by felting. The surface is finished by printing.

In Monach's process for preparing jute as a substitute for wool, the jute or jute-yarn is boiled for two hours in a solution of caustic alkali of a gravity of 60° to 80° Twaddell. After washing, it is steeped a short time in a weak solution of sulphuric acid to neutralize the alkali, and is then washed and dried.

Jut'ting-out. (*Architecture.*) A projection; said of windows, corbels, cornices, etc.

Jutty. (*Architecture.*) A projecting part of a wall, as of a prominent course.

Jut-win'dow. (*Carpentry.*) A bow-window, projecting from the face of a building. A *bay-window.*

Digitized by Google

K.

Ka'jak. The boat of the Esquimaux. It is from 18 to 20 feet long, 18 inches broad in the middle, tapering to both ends, and about a foot deep. It has no outriggers, and is difficult to manage. It is covered with skins, and closed at top with the exception of a hole in the middle, which the boatman occupies, sitting on the floor of the boat.

The *kajak* is the men's boat. The *umiak* is the women's boat; has a flat bottom, and is much larger. It is made of slender laths, fastened with whalebone, and covered with seal-skin.

Ka-lei'do-phone. An instrument invented by Professor Wheatstone, to illustrate the phenomena of waves of sound. An elastic thin bar is fixed by one of its extremities, and at its free end carries a silvered or polished ball; a ray of light is reflected from this ball, and when the thin plate is put in vibration, the fine point of light describes various curves, corresponding with the musical notes produced by the vibrations.

Ka-lei'do-scope. An optical instrument, invented by David Brewster, 1814–17. An arrangement of mirrors produces a symmetrical reflection of beautiful images, derived from the association of pieces of colored glass, which assume new relations as the tube is slowly rotated.

This instrument is first noticed by Baptista Porta in his "Natural Magic," under the name of polyphaton. Kircher describes a similar invention of his own, but the application of two reflectors so inclined to each other as to form symmetrical images, changing as the instrument is rotated, was invented by Brewster.

"He subsequently found means to obtain multiplied images of such objects as flowers, trees, and even persons and things in motion, and thus the importance of the instrument was greatly increased. For this purpose, he caused the two mirrors to be fixed in a tube as before, but this tube was contained in another, from which, like the eye-tube of a telescope, it could be drawn at pleasure towards the eye. At the opposite end of the exterior tube was fixed a glass lens of convenient focal length, by which were formed images of different objects in the upper section, and which, being multiplied by successive reflections from the mirrors, produced in the field of view symmetrical patterns of great beauty. The properties of the instrument have been greatly extended; and when it is so constructed that there may be projected on a screen a magnified image of the whole pattern, and the tube is supported on a ball and socket joint, the figures in its field may be easily sketched by a skillful artist." — TIMBS.

Kal'lif-thor'gan. A musical instrument played as a piano, and imitating the effect of a violin, violoncello, and double-bass.

Kal'muck. (*Fabric.*) A coarse, shaggy cloth, resembling a bear-skin.

A coarse, colored, cotton cloth made in Persia.

Kal'so-mine. A mixture of clear glue, Paris white, and water, laid on to a wall as whitewash. Commence by soaking 4 ounces of glue in a quart of warm water for 24 hours; then add a pint of water, and the tin vessel should be placed in a kettle of hot water over a fire, the glue being agitated till it is thoroughly dissolved and the solution quite clear. Put 5 or 6 pounds of powdered Paris white into a large bucket, and add hot water sufficient for the mixture to be of the consistency of cream; color according to taste. Then mix the glue-water with it, stir it well, and paint the walls with the mixture with the usual whitewash-brush.

Kamp-tu'li-con. A floor covering made of india-rubber, gutta-percha, and cork. The two former having been liquefied, the other is added in the form of fine dust. (Galloway's English patent, February 14, 1844.) The mixture, while warm and soft, is pressed into sheets between rollers. It is very elastic, and is printed like floor-cloth.

Ka'o-lin. The Chinese name for porcelain clay; which is derived from the decomposition of felspar. In the Chinese manufacture of porcelain the *kaolin* is mixed with a fusible earthy matter, call *petuntse*. See PORCELAIN.

Kas. 1. A horsehair sieve.

2. A negro drum.

Kath'e-tom'e-ter. See CATHETOMETER.

Keck'ling. (*Nautical.*) A mode of protecting a cable or hawser from chafing at the hawse-hole, or from being chafed by ice, etc., by means of a wrapping or serving of rope, small chain, or other envelope.

Kedge. A small and portable anchor, used in warping and other of the lighter duties of an anchor. See ANCHOR.

Keel. 1. (*Shipbuilding.*) *a.* The lower longitudinal beam of a vessel, answering to the spine, and from which the ribs proceed.

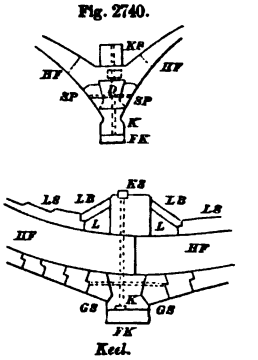
In wooden vessels, an additional timber beneath is called the *false keel.*

A timber resting on the flooring timbers and above the keel is the *keelson.*

Timbers secured parallel to the latter are the *sister-keelsons,* or *side-keelsons.*

Heavy timbers resting on the timbers before mentioned, and lying athwartships, are *cross-keelsons,* for sustaining the boilers and engines of steamships.

Fig. 2740.



Keel.

The *bilge*-keel is a longitudinal piece fastened on the bilge to protect it, or to prevent rolling, in the case of iron vessels without true keels.

The keel is *laid* upon blocks whose upper surfaces form an angle of about 3° with the horizon. The blocks are about three feet high and four feet apart.

In England the keel is usually of elm, the pieces being scarfed together to attain the requisite length. In a first-rate line-of-battle ship the keel is 20 × 20 inches. American elm does not suit for the purpose, and white oak is used.

A *sliding* keel is a board amidships, working in a trunk in the line of the keel and extending from the bottom to the deck. It is lowered to form a lee-board for a vessel when under canvas.

The upper portion of Fig. 2740 shows, in cross-section, the keel in the cant frames.

K, keel. *SP*, stepping-pieces.
FK, false keel. *HF*, half-floors.
D, deadwood. *KS*, keelson.

The lower figure shows the keel nearer to midship.

Digitized by Google

K, keel.
KS, keelson.
FK, false keel.
HF, half-floors.
GS, garboard-strakes.
L, limbers.
LB, limber-boards.
LS, limber-strakes.

b. A small coal-carrying craft, used on the river Tyne.

2. A broad, shallow, cooling vat.

Keel-boat. A large, covered boat, used on American rivers. Before the time of steamboats, keel-boats were used for passengers and merchandise, being floated down stream and *poled* up stream.

Keel-fat. A cooler for wort, etc.

Keel'son. (*Shipbuilding.*) A longitudinal piece above the floor-timbers, binding them to the keel.

The *sister-keelsons* lie on each side of the keelson. Also called *side-keelsons*.

The *intercostal-keelson* is a short piece between frames.

Rider-keelsons are auxiliary keelsons placed above the *main-keelson* to give additional strength. See KEEL.

Keep. (*Architecture.*) The tower or place set apart in a castle for the confinement of prisoners. A *redoubt*.

Keep'er. A ring, strap, pocket, or the like device for detaining an object; as, —

1. (*Harness.*) The *keeper* of a buckle-strap; a loop which slips upon the end of the strap, or into which the strap slides.

2. A ring worn on the finger to keep a larger one on.

3. A jam nut.

4. The box on a door jamb into which the bolt of a lock protrudes, when *shot*.

5. The armature of a magnet. A piece of iron which connects the two poles.

6. The mousing of a hook, which prevents its accidental disengagement.

7. The gripper of the flint in a flint-lock.

Keeve. A large vessel or vat, used for mashing, fermenting, or storing beer. See BECK; VAT.

For holding a bleaching liquor or alkaline lye. See KEIR.

For elevating ores. See CORF.

An iron-bound tub of a truncate, conical form, set upon the smaller end, and used for collecting the fine grains of copper. In use it is kept half full of water, and the contents agitated by a shovel till the heavier particles seek the bottom, leaving the water to be dipped out and the refuse lighter upper stratum to be removed.

Fig. 2741.

Tossing with the Keeve.

In the illustration the *keeve* is shown with a central shaft and a paddle, which is revolved until all the mineral contents are involved in the gyration of the water, when the action is moderated and the heavier particles gradually assume the lower position and eventually reach the bottom. The action is called *tossing* or *tozing*. Other contrivances in which the comminuted ore is agitated in water are known as jiggers, etc. See METALLURGY.

Keir. A vat for holding a bleaching liquor. The alkaline vat of a bleachery. See BUCKING-KIER.

Kel'lach. A wicker sledge or cart used in Scotland.

Kem'e-lin. A brewer's vessel.

Ke-men'geh. An Arab violoncello, with two strings.

Kemps. 1. Impurities of fur; that is, knots and hairs which do not possess the felting property.

2. The coarse, rough hairs of some grades of wool.

Ken'net. (*Nautical.*) A *kevel* or large cleat.

Ken'nets. A coarse cloth made in Wales.

Kent-bu'gle. The key-bugle invented by Logier early in this century, and named after the Duke of Kent, the father of Queen Victoria. It has six keys, and is the predecessor of the great tribe of cornets.

Kent-ledge. Pigs of iron for permanent ballast, laid over the keelson-plates.

Ke'per. A German twilled linen goods resembling *marsella*. *Kofer*.

Ker'a-tome. A surgical knife used in the operation for *artificial pupil*. Also called *iridectome* or artificial-pupil knife. It is spear-pointed, double-edged, and may be straight or angular. It is used for making an incision through the cornea into the anterior chamber, and by slight movements of its cutting edges, upward or downward, the wound is made of proper dimensions, after which the operation is completed with other instruments. Also used in operations for cataract.

Kerb. (*Masonry.*) Called also curb.

1. The assemblage of stones surrounding the mouth of a well or similar opening. See CURB.

2. The line of stones set on edge which separates a foot pavement from the gutter or carriage-way.

Kerf. The slit or notch made by a saw.

Kerf'ing-ma-chine'. A machine for sawing a series of parallel kerfs on one surface of a board, in order to enable it to be bent.

It consists of a table and a series of circular saws upon a horizontal mandrel, the latter being vertically adjustable, so as to allow the saws to project above the surface of the table to an extent equal to the desired depth of kerf.

Ke'rite. A compound invented by Austin G. Day (patent October 9, 1866), and by him termed *kerite* or *artificial caoutchouc*, and in which the raw caoutchouc or rubber is replaced by tar or asphaltum, which, combined with animal or vegetable oils, is vulcanized by sulphur, the product closely resembling rubber, the hard and soft varieties being produced by different proportions, etc. The principal use of kerite has been as an insulating material in telegraphy.

Day, in his patent, gives the following formulas. Parts by weight. Heats to 260°, gradually increases to 300° F.

a. Linseed-oil, 2; cotton-seed oil, 1; raw turpentine, 2; sulphur, 2. Time, 1 hour.

b. Linseed-oil, 2; castor-oil, 1; liquid coal-tar, 2; petroleum, 1; turpentine, 2; sulphur, 2. Time, 30 minutes or more.

c. Linseed-oil, 2; petroleum, 1; crude turpentine, ½; sulphur, 4. Time, 35 minutes.

Ke'rite-wire. Wire used in telegraphy, insulated by a covering of *kerite*.

Kern. 1. (*Printing.*) The part of a letter which overhangs the shank. It occurs more frequently in *italic* than in Roman: "*jolly old fag*" embraces the kerned letters of an *italic* font.

2. (*Milling.*) A hand-mill for grain. See QUERN.

Ker'sey. (*Fabric.*) A probable corruption of Jersey, whence it came. A coarse ribbed cloth made from wool of long staple.

Ker-sey-mere'. (*Fabric.*) A light woolen twilled goods with an oil finish, for men's wear.

Digitized by Google

Named from *Kersey*, in Yorkshire, England. *Cassimere.*

Ker-sey-nette'. (*Fabric.*) A thin woolen cloth. *Cassinette.*

Ketch. (*Vessel.*) An almost obsolete form of two-masted vessel, carrying a tall, square-rigged main-mast forward, and a shorter fore-and-aft rigged mizzen abaft.

Being a favorite form of mortar vessel, we frequently read of *bomb-ketch* in the wars of a past age.

Ket'tle. A metallic vessel in which water or other liquid is boiled. In sugar-houses kettles are arranged in rows called *batteries.* Capacities and sizes of sugar pans and kettles are as follows: —

Shallow.

Size.	Diameter.	Depth.	Rim.
25 gallons.	29½ inches.	10½ inches.	3½ inches.
30 "	31½ "	12½ "	3½ "
40 "	33½ "	13 "	4 "
50 "	39 "	13½ "	4½ "
60 "	42 "	15 "	4½ "
80 "	46½ "	16 "	4½ "
100 "	49½ "	17 "	4½ "
125 "	53½ "	18½ "	5 "
150 "	56½ "	20 "	5½ "

Weigh about 5½ pounds to a gallon.

Deep.

Size.	Diameter.	Depth.	Rim.
20 gallons.	27 inches.	9½ inches.	1½ inches.
30 "	29 "	13½ "	1½ "
40 "	34 "	15 "	2½ "
50 "	33 "	13½ "	2½ "
60 "	41 "	17 "	2½ "
80 "	42 "	18 "	2½ "
100 "	47 "	17½ "	3 "
120 "	49½ "	18½ "	3 "

Weigh about 5 pounds to a gallon.

Extra Sizes.

Size.	Diameter.	Depth.
200 gallons	70 inches.	24 inches.
250 "	75 "	27 "
300 "	79 "	29½ "
350 "	81 "	30½ "
400 "	82½ "	31½ "
450 "	84 "	32½ "
500 "	85 "	33 "
550 "	86 "	34 "
600 "	87 "	35 "

Weigh about 7 pounds to a gallon.

The old mode of making brass kettles was by hammering upon a sheet of metal, until by degrees the required shape was assumed. The plan now in use is known as "Hayden's patent," December 15, 1851. Square blanks of sheet-brass are cut into circles of a diameter corresponding to the size of kettle required. After annealing, the metallic disks are brought in contact with cast-iron chucks revolving horizontally with great velocity. A small steel friction roller, resembling a button, is then brought in close contiguity to the metal, and, running along the outer surface of the blank, spins it out to the shape of the mold. Four such operations are commonly required before the kettle assumes its finished form, the metal requiring to be annealed after each. The course of the roller is marked by the concentric rings which are found upon most of the brass kettles in market. The processes of wiring, fixing on the ears and bales, are all required to make the kettle complete. Sizes range from ½ gallon to 32 gallons capacity.

Ket'tle-boil'er. An old form of steam-boiler whose lower portion was shaped as an inverted conical frustum, and the upper part a dome. The form resembles that of a tea-kettle.

Ket'tle-drum. The *kettle-drum* is so named from its resemblance to a hemispherical kettle. It is formed of thin copper, and has a head of parchment or vellum. Kettle-drums are used in pairs, slung on each side of the withers of a cavalry horse. One drum was tuned to the key-note and the other to the fifth of the key in which the piece in which they are to figure is written. The tuning is by a hoop and screws.

They are now usually supported upon tripod and used in orchestras. The *tam-tam* is the original kettle-drum, and has for its congeners the *darabookah* of Egypt, the *derbekkeh* of Syria. These are the lineal descendants of the Egyptian drum so commonly used in the festivities of the Pharaonic Egyptians. See DRUM.

This brass band or orchestral instrument is classed with those of *percussion*, in contradistinction to *stringed* and *wind* instruments. *Kettle-drums* are used in pairs, of which the larger is used for the lower sound.

Drumsticks are of three kinds: *wooden, wood covered with leather, sponge ends.*

Drums are also played *open* or *muffled.* The latter is by a piece of cloth covering the head and deadening the sound. See DRUM.

Ket'tle-fur'nace. (*Metallurgy.*) *a.* A basket-furnace or cresset in which lead or solder is melted for plumbing.

b. A furnace in which a kettle or kettles are set in a brick arch, as in sugar-boiling furnaces; or above a box-furnace, as in agricultural boilers. See EVAPORATOR.

Ket'tle-stitch. (*Bookbinding.*) The stitch made in sewing at the head and tail of a book.

Kev'el. 1. (*Nautical.*) *a.* A large cleat for belaying. Sometimes formed by the ends of the top timbers which rise above the gunwale, or formed by timbers projecting at a small angle from the sides to belay large ropes, such as the sheets and tacks of the main-sail and fore-sail. See CLEAT.

b. A frame for spreading the main-sail.

c. An anchor-*palm.*

2. A stone-mason's hammer, used in spalling stone, and having a blade and point at the respective ends.

Kev'el-head. (*Nautical.*) The end of a top timber projecting above the gunwale and acting as a bitt or kevel, to belay large ropes, to fasten or *veer away* a warp, etc.

Key. 1. (*Machinery.*) *a*, a joggle-piece forming a lock or draw-pin in a joint. See HOOK-BUTT.

b, a wedge-piece of iron used for tightening the brasses of a bearing.

c, a fastening piece, such as a wedge or cotter in a chain. A *fore-lock.*

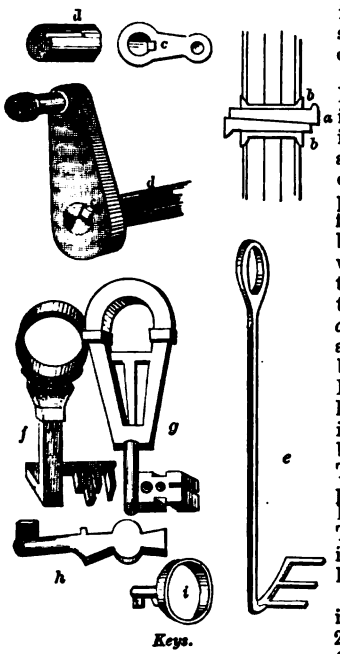
d, a piece *a* sometimes used in a mortise in connection with *gibs b*, in attaching a strap-head to a connecting rod.

e, a fin or wedge *c* fastening a crank on its shaft *d*. A long key on a shaft, which prevents the revolution of the wheel thereon, but permits longitudinal motion, is called a *spline.* See SPLINE; FEATHER.

2. A spanner or wrench by which to turn a coupling-piece.

Digitized by Google

Fig. 2742.



Keys.

3. A portable instrument for shooting the bolt of a lock.

The locks of Egypt were sliding bolts, moving in keepers attached to the doors, and were probably moved from the outside by keys, somewhat similar to that shown in the illustration *c*, which is an ancient iron key brought from Egypt by Wilkinson. Ancient iron keys have been found at Thebes, and are preserved in the British Museum. They are from 1¾ inches to 5 inches long. See LOCK.

We read also in Judges iii. 23 – 25, that "Ehud went forth through the porch and shut the doors of the parlor upon him and locked them," and "his servants . . . . took a key, and opened them."

The modern key of Mosul, in the vicinity of what remains of the ancient Nineveh, is a long bar of wood, with two projections towards the end about a foot in length. As one traveler remarks, it is "well qualified, not only to open a door, but to knock down any one who might attempt to enter without permission."

The invention is ascribed by Pliny to Theodore of Samos, 730 B. C., but keys are mentioned in the siege of Troy, 1193 B. C. The bolt of the lock mentioned in the Odyssey was moved by pulling a latch-string which passed through the door and hung outside. Denon has engraved an Egyptian lock which no doubt had a key.

The Roman keys were very various (see *f g h i*, Fig. 2742), some like the old Egyptian and others like the modern. The *ring*, or *bow*, *stem*, and *bit* are all there. Some have hollow barrels, like our trunk keys. Thirty varieties are shown by Montfaucon.

The keys found at Herculaneum show that the art of lock-making (A. D. 79) was well understood.

4. (*Joinery.*) *a.* A piece of timber let transversely into the back of a board, which consists of several breadths, for the purpose of preventing warping.

b. The last board of a floor or platform which is driven into position and keys up the others.

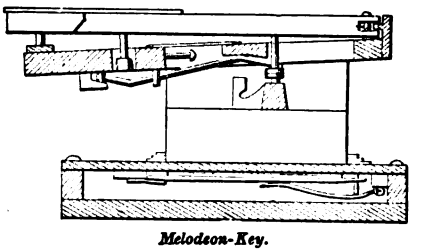
c. A tenon piece, of the nature of a dowel entering coincident parts in matched boards, and holding them together, or in correspondence.

d. The roughing on the under side of a veneer, which is made by a *toothing-plane*, and is designed to give the glue a better chance of adhering.

e. One of the wedge-shaped pieces or *striking-plates* beneath the ribs of a bridge *centering*, and by driving in which the *centering* is struck and the arch left self-sustained.

5. (*Music.*) *a.* One of a series of levers in a

Fig. 2743.



Melodeon-Key.

piano, organ, etc., which are operated by the fingers of the performer. (See PIANO MOVEMENT.) Keys are *manual* and *pedal*. *b.* The fundamental tone of a movement; or of an instrument, and to which its modulations are referred.

An illustration may be afforded by giving a comparative statement of the different keys of the *cornet-à-pistons*, the *trumpet*, and the *horn*.

	Cornet-à-Pistons.	Trumpet.	Horn.

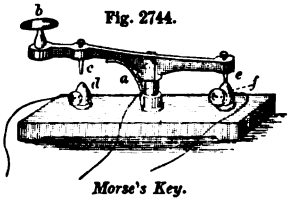
			B ♭
			C

See Berlioz's "Instrumentation and Orchestration."

6. (*Telegraphy.*) A device for breaking and closing electric circuits, so that the current may be interrupted to give signals.

Fig. 2744.



Morse's Key.

Morse's key for transmitting the currents by which the characters of his alphabet are indicated, consists of a pivoted lever provided with a spring *a*. When a message is being transmitted, the operator, by tapping on the button *b*, brings the points *c d* in contact, connecting the battery and line wire, and producing the combination of dots and dashes which form the Morse alphabet. When not in use for transmitting, the spring *a* keeps those points out of contact, and currents arriving by the line wire are conducted by the points *e f* to the indicator or to the relay.

7. A tooth-drawing instrument.

8. (*Masonry.*) The highest stone of an arch.

9. (*Plastering.*) That portion of the *rendering* or first coat of hair plaster which forces its way between the laths, and holds the body of the plaster in place.

10. (*Well-boring.*) A bent bar of iron spanning

Digitized by Google

the boring-rod just beneath a coupling, and serving to support the train of rods at the bore-mouth.

11. A term applied to instruments which are inserted and turned. See under the following heads:

Bedstead-key.	Key (*plastering*).
Bit-key.	Key-seat.
Box-key.	Key-screw.
Clicket.	Keystone.
Dental key.	Key-valve.
False-key.	Key-way.
Faucet-key.	Latch-key.
Foot-key.	Linch-pin.
Fore-lock key.	Master-key.
Fox-key.	Pass-key.
Key-bed.	Pick-lock.
Key-board.	Press-key.
Key-bugle.	Screw-key.
Key-fastener.	Skeleton-key.
Key-file.	Spanner.
Key-grooving machine.	Stepped key.
Key-hole guard.	Telegraph-key.
Key (*carpentry*).	Tuning-key.
Key (*lock*).	Turn-key.
Key (*machinery*).	Watch-key.
Key (*musical instrument*).	Wrench.

12. A *quay* or wharf.

Key-bed. The groove or seat of a key, which secures a wheel on its shaft.

Key-board. The finger-board of an organ, piano, or melodeon, on which the keys are exposed to view and touch.

Before the end of the sixteenth century, the present chromatic scale and key-board were introduced, the latter having the seven white and five black keys in each octave. The octave was divided into twelve equal parts about 1548.

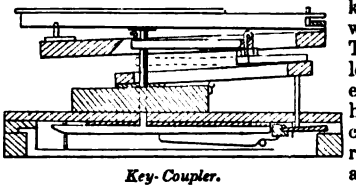
Key-bolt. One secured by a cotter or wedge instead of a thread and nut.

Key-bu'gle. (*Music.*) A brass wind-instrument with keys, seven usually. It will traverse chromatically a compass of more than two octaves, beginning from B♮ beneath the stave up to the C above the stave.

The bugle with pistons or with cylinders has a lower compass than the preceding.

Key-coup'ler. An attachment in a melodeon or parlor-organ to couple keys in octaves when desired. The coupling-levers cross each other, have their fulcrums at their rear ends, and are attached at their intersection. When the levers do not act, an additional pressure is put upon the valves.

Fig. 2745.



Key-Coupler.

Keyed Har-mon'i-ca. (*Music.*) An instrument in which plates of glass are struck by keys. The *glockenspeil* has bells struck by keys; a variation of the latter approaches the character of the keyed harmonica, having bars of steel for sounders.

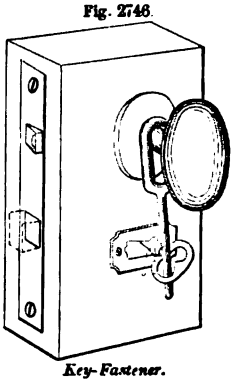
Key-fas'ten-er. An attachment to a lock to prevent the turning of the key by an outsider.

Key-file. A flat file having a constant thickness, and used in filing the ward-notches in keys.

Key-groov'ing Ma-chine'. (*Metal-working.*) One for slotting the center-holes of wheels to make a groove for the key, which fastens the wheel to its shaft, so that it may not turn thereon.

It is a modification of the planing-machine, which grew out of the slide-rest. It was invented by Roberts of Manchester, England. The wheel to be grooved is dogged to the sliding-bed and fed beneath the tool, which is reciprocated vertically above it by means of a crank or eccentric. To make the groove taper, the work is tipped to the required extent; to make several key-ways, the wheel is mounted on a turn-table with notches cut in its edges, to indicate the exact relative positions, as in planing squares, hexagons, etc. See Fig. 2748.

Fig. 2746.

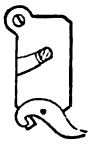


Key-Fastener.

The *slotting*-machine is an outgrowth of the *key-grooving* machine.

Key-guard. A shield which shuts down over a lock-key to prevent its being pushed out of the lock from the outside. In the example, a slotted escutcheon on the plate shuts over a flattened portion of the key-shank to prevent its being turned by an outsider. A pawl acts as a detent for the escutcheon.

Fig. 2747.



Key-Guard.

Key'hole-pro-tect'or. Mitchell and Lawton's English patent, 1815, has a revolving curtain for closing the keyhole.

Day and Newell's parautoptic lock has a revolving ring or curtain, which moves with the key and shuts the hole, so that wires and tools cannot be introduced alongside the key.

Mordan's keyhole protector (English), 1830, has a short pipe which, after the door has been locked, is thrust into the keyhole; attached to the pipe is a small lock so contrived that, on turning its key, two lancet-shaped pieces fly out laterally and bury themselves in the wood. The escutcheon cannot be removed until the small key has reacted upon the small lock; and until this removal has taken place, the large key cannot reach the keyhole.

Key'hole-saw. A long, thin saw. See COMPASS-SAW.

Key-mod'el. A mode of modeling vessels by shaping boards according to the horizontal lines, and laying them upon one another horizontally.

Key-pipe. The pipe of a lock in which a key is turned.

Key-screw. A lever, wrench, or spanner, for turning screws.

Key-seat. The groove in a wheel and shaft to receive the key which secures them together.

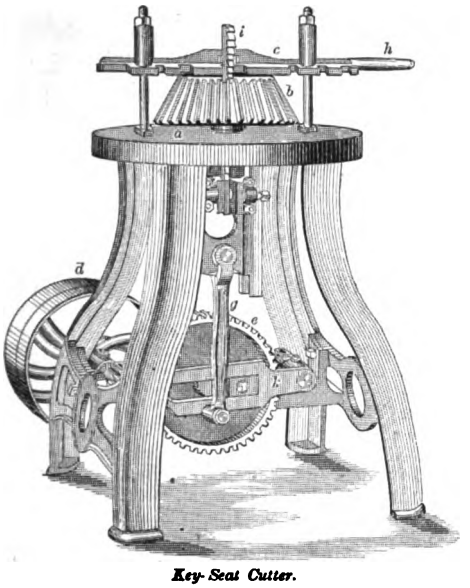
Key-seat Cut'ter. A machine for cutting grooves for keys in the center-holes of pulleys and gear-wheels. The wheel *b* is clamped by binder *c* and bolts to the table *a*. The cutter or saw *i* is reciprocated by wheel *e*, lever *k*, and pitman *g* below, driven by band applied to the pulley *d*. The saw is passed up to its work by means of the lever *h*, by the arrangement of the wrist-box sliding in the slotted lever *k*; a slow downward movement is attained, and a quick return, at which time the pressure on the lever *h* is slacked.

The machine for cutting key-seats has a horizontal plate for attachment to the table of a planing-machine, and the plate has a vertical portion, to which a wheel may be clutched. A mandrel, having a planing-tool, is secured by a jointed section to the head-stock of the planer, and is made to reciprocate within the eye of the wheel. The forward

Digitized by Google

end of the mandrel passes through a guide-ring, which has trunnions with bearing in a frame verti-

Fig. 2748.



Key-Seat Cutter.

cally adjusted in the guide-standards by means of a screw.

Key'stone. 1. (*Masonry.*) The central voussoir at the vertex of an arch. The row or course of said stones along the crown of an arch is the *key-course.*

The length of the keystone, or the thickness of the archivolt at top, is $\frac{1}{15}$ or $\frac{1}{18}$ of the span.

2. In chromo-lithographic printing, the stone on which a general outline of the picture is drawn or photo-lithographed. Its object is to furnish a guide for the production of the work upon the several color-stones. Transfers from the keystones in common printing-inks, more properly called "offsets" to distinguish them from transfers from which impressions can be printed, are made upon as many stones as there are colors required. The outlines thus obtained are identical in form and size, and when, by means of the crayon or fluid litho-ink, — with subsequent etching, — certain portions of each are given the power of printing, the superimposition of impressions from all upon a single sheet of paper, each being printed with its proper color, will give the desired result in perfect register. The keystone may be one of those used in printing, but in the higher class of work it is an outline merely, used to aid the artists in the manner described.

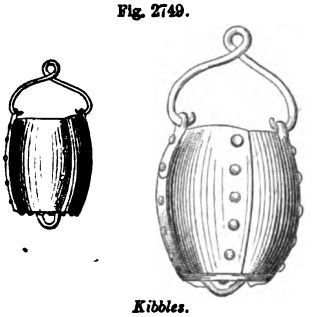
Key-valve. (*Music.*) The pad or plug which closes an aperture in a wind-instrument. The valve being retracted the wind passes through, and the note is sounded. Valves are applied to the openings in the reed-board of a reed or organ, melodeon, accordeon, or concertina; on the faces of the keys of flutes, clarinets, flageolets, cornets, bugles, etc.

Key-way. A slot in the round hole of a wheel for the reception of the *key*, whereby the wheel is fastened to the shaft.

Kib'ble; kib'bal. (*Mining.*) A strong iron kettle with a bail, made of ¼-inch sheet-iron, riveted, and used as a bucket in raising ore from a mine. The term is used in copper-mining, and may have a Cornish origin.

Kib'bling-mill. A hand-mill of steel attached to a post, and used for crushing or grinding beans or other grain for feed. A *kibbling-machine.*

Fig. 2749.



Kibbles.

Ki-bit'ka. A Russian one-horse vehicle with two wheels. The kibitka is of various sizes, and may be either completely covered, entirely open, or provided with a hood behind. It has a single pair of long runners, and, to prevent upsetting, is provided with a guard-frame, which, starting from the body of the sleigh in front, spreads out some twelve or eighteen inches from the sides at the rear end. As soon as the vehicle tips, this framework touches the ground, and must break before the vehicle can capsize.

Kick. (*Brickmaking.*) The piece of wood fastened to the upper side of a *stock-board* to make a depression in the lower face of the brick as molded.

Kid. A bundle of bushes or sticks planted on a beach to stop shingle or gather sand, to act as a *groyne.*

Kid'der-min-ster Car'pet. A carpet so called from being made somewhat extensively at a town of that name in England. The carpet is also known as Scotch, for a similar reason. Another of its names, *ingrain,* signifies that it is made of wool or worsted dyed *in the* grain; that is, before manufacture. Its names *two-ply* or *three-ply* indicate the number of webs which go to the making of the fabric.

It is composed of two webs, each consisting of a separate warped woof; the two are interwoven at intervals to produce the figure, one part being above and the other below. When different colors are used, the pattern will be the same on both sides, but the colors reversed.

Kid'dle. A weir or fish-trap.

Kid'ney-link. (*Harness.*) A coupling for the harness below the collar.

Kid'nip-pers. (*Molding.*) Nippers used in gun-molding for bringing the hoops taut around the mold.

Kil'las. (*Mining.*) The clay-slate in which the ores of copper and tin are found in Cornwall, England.

Kiln. A furnace for calcining; as plaster of paris or carbonate of lime in its shapes of marble, chalk, or limestone. See LIME-KILN.

Or for baking articles of clay in the biscuit condition. A *biscuit-kiln.* See GLAZE-KILN.

Or for drying malt, hops, lumber, grain, fruit, starch, biscuit, etc.

Or for vitrifying articles of clay, such as pottery, porcelain, bricks. See PORCELAIN; BRICK.

Herodotus speaks of baking bricks in kilns. The latter word may refer to a clamp, however. They certainly used kilns of some kind for their pottery, which was made of many kinds.

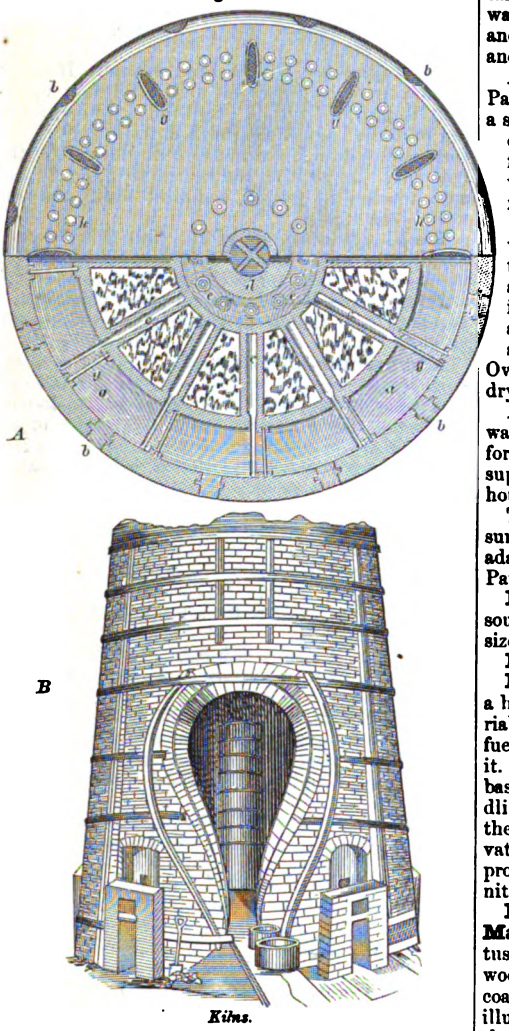
Hoffman's annular kiln (*A*, Fig. 2750), patented June 13, 1865, consists of a circular channel, *a a*, which receives the objects to be fired, introduced through doors, *b b*, in the outside wall. Flues, *c c c*, lead from the hearth of the kiln to the smoke-chamber, *e e e*, which surrounds the base of the chimney, *d*. The communication of each flue can be cut off at will, by means of a cast-iron, bell-shaped damper. An intercepting slide can be lowered in grooves, *g g*,

Digitized by Google

built into the walls of the kiln, immediately after each flue, so as to separate it at any distinct or equidistant compartment. The fuel passes through apertures *h h*, which are constructed in the arch, and falls through channels formed by the objects to be burned to a chamber in the hearth of the kiln, from which a certain number of small flues radiate to produce a free current from fire to fire.

The kiln has twelve compartments, to which there are twelve entries or doorways *b b*, also the same number of flues *c c c*, communicating with the smoke-

Fig. 2750.



Kilns.

chamber *e e*, and just as many openings *g g* in the arch for the reception of the large intercepting damper slide; thus the kiln can be divided at any one of the twelve parts.

The apartments are used successively; while one is being charged with bricks, tiles, or pottery, others are being burned, others are cooling, and one or more may be discharging.

The kiln-fire is supplied with warm air drawn through the apartments which are being cooled. The heat passing from the apartments where the fire is burning heats the one next in series to such an extent that the fuel introduced into the latter is ignited, and it commences burning on its own account.

Dampers in the flues connecting the apartments, and in the radial flues leading to the chimney stack, permit the caloric current to be turned as required.

An older form of pottery kiln for burning crockery is shown at *B*.

The piles of seggars are introduced through the large opening in front; when the kiln is fully charged this is bricked up, and fires started in the furnaces surrounding the kiln. The heat is maintained until, in the judgment of the operator, the ware is sufficiently baked, when the fires are drawn, and when sufficiently cool the brick-work is removed and the seggars withdrawn.

A peculiar kiln is employed in the vicinity of Paris for burning plaster of paris. This substance, a sulphate of lime, frequently contains a proportion of the carbonate, as is the case in that obtained from the great quarry of Montmartre, near Paris, where it is employed instead of lime for making mortar.

The kiln is about ten feet long, and has walls at two sides and one end. Within, longitudinal walls are built up of the blocks of gypsum as they come from the quarry, the interspaces being filled with billets of wood. Over these, arches are built with the gypsum blocks, sufficiently stable not to fall in when the fuel is consumed. Over these are laid alternate layers of charcoal or dry wood to the depth of eighteen or twenty inches.

An aperture about six inches square in the end wall provides for draft. Fire is kindled in the flues formed at the other end, and maintained by farther supplies of small wood for from twenty-four to forty hours, until the calcination is complete.

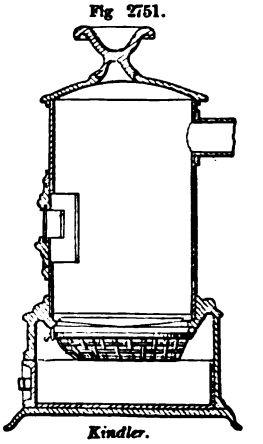
The cement made by combining the calcined gypsum with water and sand sets quickly, and is better adapted for stone, the common building material of Paris, than for brick.

Kin. A Chinese instrument having a body, a sounding-board, and five silken strings of different sizes.

Kin'cob. (*Fabric.*) An East-Indian laced satin.

Kin'dler. An attachment to a stove, by which a body of easily lit material is brought against the fuel in the stove to kindle it. In the example, the basket to contain kindlings is hinged beneath the grate, and when elevated in front is in a proper position for the ignition of the fire.

Fig 2751.



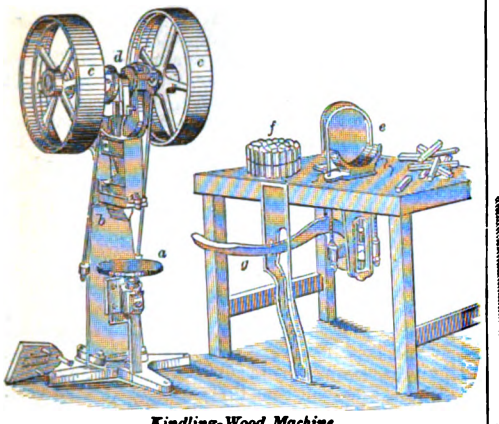
Kindler.

Kin'dling-wood Ma'chine. An apparatus for splitting the short wood used for kindling coal fires, etc. In that illustrated in Fig. 2753 the vertically reciprocating cutter is operated by a crank shaft rotated by pulley and belt connections, making about 125 strokes per minute; the wood is placed on a circular table below the cutter, and the machine is adjusted to cut different lengths by varying the elevation of the table and by a clearing plate, shown detached to the left of the base of the machine. The bundling-machine is operated by a lever, which

Digitized by Google

works a toggle-joint, causing a loop to compress the bundle, placed in a semicircular rest, while being tied.

Fig. 2752.



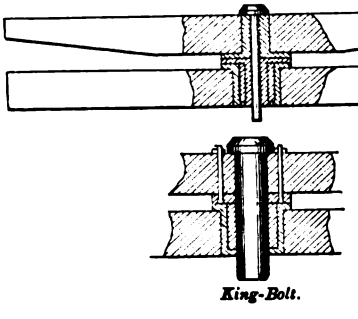
Kindling-Wood Machine.

In another bundling-machine, the split wood from the cutter falls into boxes on an endless belt, and is conveyed to the clamps into which the charges are dropped. These are closed by cam movement, a wire is passed around the bundle and automatically cut and twisted.

Still another machine has a cutting-edged cylinder, to which the bundles are delivered by a feed-wheel being forced through by a plunger and trimmed smooth.

Ki-ne'to-scope. An instrument invented by Perigal, for illustrating the result of the combination of circular movements of different radii in the production of curves. Also called *kinescope*.

Fig. 2753.



King-Bolt.

King-bolt. (*Vehicles.*) *a*. A vertical bolt which attaches the front of the body to the fore-carriage, and forms the axis of oscillation when the said carriage is turned sideways.

b. A similar part in a car, which forms the axis of revolution of the car upon the truck in turning curves. See CAR-TRUCK.

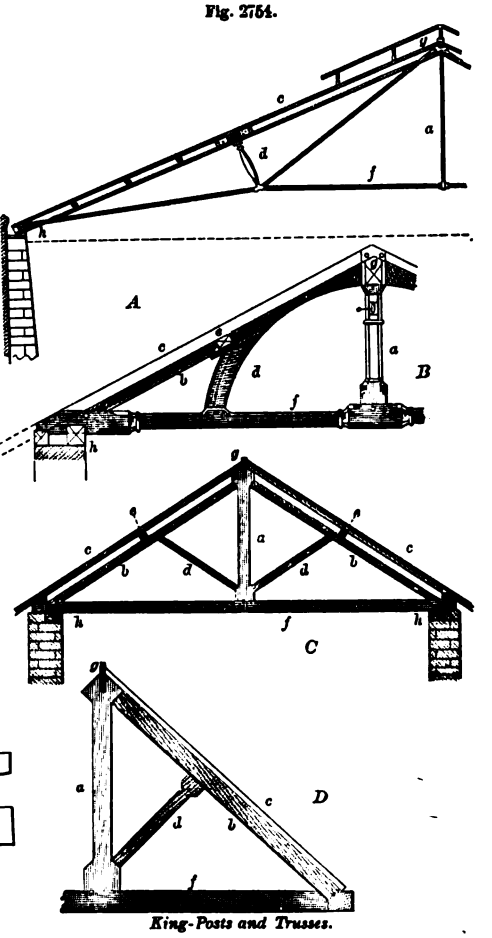
In the example, an elastic sleeve intervenes between the king-bolt and the metallic bushing, to absorb the jar.

King-post. (*Carpentry.*) A main post beneath the crown or ridge of a roof-frame.

Also known as *crown-post* or *joggle-post*. King-post trusses have several minor variations: —

a, king-post. (*King-rod* in the upper figure).
b, principal rafters.
c, rafter.
d, strut or purlin-post.
e, purlin.
f, spring-beam or tie-beam.
f, tie-rod (upper figure).
g, pole-plate.
h, wall-plate.

Fig. 2754.



King-Posts and Trusses.

A is a roof on the quay Jemappes, Paris.

B is from the roof of the church of Lagorce, France, twelfth century.

C is an ordinary barn-roof.

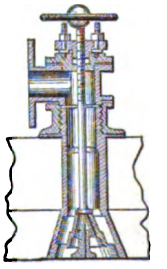
D a Gothic roof.

King-post Truss. See KING-POST.

King-post Roof. (*Carpentry.*) One having but one vertical post in each truss.

King-rod. A tension rod depending from the ridge of a roof and uniting with the tie-rod; occupying the position of the king-post in wooden roofs. See KING-POST (*A*).

Fig. 2755.



Kingston's Valve.

King'ston's Valve. A conical valve, forming the outlet of the blow-off pipe of a marine engine; it opens through the side of the vessel by turning a screw.

King-truss. A roof or bridge-truss framed with a KING-POST (which see).

Kink. (*Nautical.*) A sharp bend in a rope or cable which prevents its reeving through a block or a hole.

Digitized by Google

Kinsh. A crowbar used in quarrying.

Ki'o-tome. (*Surgical.*) A knife for cutting membrane; especially certain pseudo-membraneous bands in the rectum and bladder.

Kip. Leather of yearlings or small cattle. A grade between calf and cowhide. *Kip-skin.*

Kirb. See CURB.

Kish. (*Smelting.*) *a.* A carburet of iron which, when cold, appears in bright shining scales, but which is in the liquid form in the iron-smelting furnace, where, owing to its levity, it floats upon the surface. It possesses most of the properties of graphite, but contains less carbon.

b. The impurities which float on the surface of molten lead in a furnace.

Kit. 1. (*Photography.*) Also known as "inside frame." A thin, flat, rectangular frame of wood which fits within a plate-holder for the purpose of enabling the latter to carry a sensitized plate smaller than that for which it was originally designed. There may be many of these for one holder, and they often fit one within the other, forming a "nest." The inside corners, as is the case in the plate-holder itself, are provided with glass or hard rubber angle-pieces, upon which the plate rests to prevent contact between the wood and nitrate of silver solution adhering to the wet plate, which would cause stains upon the negative.

2. (Ger. *Kitt.*) A cement for stuffing canvas to place over the vents of carcasses to keep out the damp.

3. A small fiddle.

4. A large bottle.

5. A milk-pail or churn.

6. The tools of a workman or outfit of a tourist.

7. A flaring-bottomed tub for fish or butter.

Kite. 1. A light frame covered with paper or cloth, and flown at the end of a string.

Centuries of use among the Chinese, and the remarkable use by our Benjamin Franklin, have aided to make the kite respectable. Benjamin had a roughly made kite, two cross-sticks, over which was stretched a silk handkerchief, and this was flown in June, 1752. Franklin was not a boy at this time, but a mature man of 46. Betsy Trotwood observed, "Franklin used to fly a kite. He was a Quaker or something of that sort, if I am not mistaken, and a Quaker flying a kite is a much more ridiculous object than anybody else"; so he might have appeared to some of the Philadelphians. Some of his propositions for conducting and using the electric current seem strangely modern. He proposed to fire spirits, kill animals, drive machinery, and discharge guns. Some of these things he performed.

The kite has been used in scaling eminences; two remarkable occasions may be cited: the ascent of "Pompey's Pillar," a pillar of red granite 114 feet high, near Alexandria; and in the ascent of the Peter Botte Mountain in the Mauritius. It is also used for lodging a cord on steeples and other structures, to enable them to be fitted with lightning-rods or for the purpose of repair. The first wire of the foot Suspension-Bridge at Niagara was carried over by a kite.

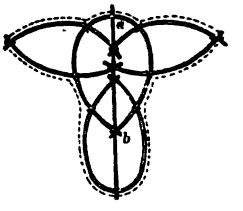
In 1827 Pocock yoked a pair of kites to a carriage, and traveled from London to Bristol. He determined that a 12-foot kite gave the power of a man, with a moderate breeze, and, when the wind is brisker, a power of 220 pounds. (This is an incomplete statement, but the figures are not ours.) The force, he states, in a rather high wind, is as the squares of the lengths of the kites; and two kites, of 12 and 15 feet respectively, will draw a carriage and four or five passengers at the rate of 20 miles per hour. (Grade not stated.) Pocock had an extra line to vary the angle of the surface of his kite, so as to adjust its tractile force, and side lines to vary the direction of the motion till it came nearly to a right angle with the course of the wind. His kites were made of varnished linen on jointed frames, so as to be folded and stored compactly.

The Indian and Chinese kites are made of Chinese paper, thin and tough, and the frames of finely split bamboo. They are gayly colored, and are sometimes made in the shape of dragons, — whatever that may be, — eagles, or spiders. The string is made of the silk obtained from a wild species of worm, and is called *nuck;* after spinning, it is treated with gum or glue, and then drawn through pounded glass. Being dried in the sun, it is ready for duty. This gritty coat is to enable it to saw asunder an adversary's line, should it become fouled, when flying on a wager or for sport. The Celestials put as much enthusiasm into the business as do the owners of trim wherries, fast nags, fleet greyhounds, rampant game-cocks, surly bull-dogs, dapper terriers, or the other thousand and one devices or excuses for actively wasting time.

Chinese kites are sometimes furnished with various æolian attachments which imitate the songs of birds or the voices of men. The pigeons also in Pekin are frequently provided with a very light kind of æolian harp, which is secured tightly to the two central feathers of their tails, so that in flying through the air the harps sound harmoniously.

The frame of the Japanese bird *kite* is made of thin bamboo, and is covered with colored paper. The wings, which are somewhat concave, and fall back a little, are dark maroon, and the body and tail represent a bird. Small white twine is used. By various devices, the hovering and soaring of a hawk can be admirably imitated. Length of middle cane 20 inches, spread of wings 26 inches; *a b*, points where the "belly-band" must be attached. Dotted lines show the paper.

Fig. 2756.



Japanese Bird-Kite.

2. (*Nautical.*) One of the unusual sails above the royal; *sky-sails, moon-rakers,* etc.

Kit-ty-sol'. (Sp. *Quitasol.*) The Chinese paper parasol.

Klick'et; Klink'et. (*Fort.*) A gate in a palisade for the passage of a sallying party.

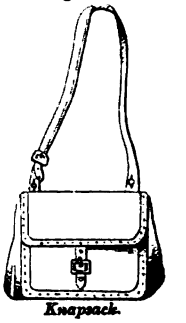
Kli-nom'e-ter. An instrument for measuring the angle of the dip of strata.

Knap'ing-ham'mer. (*Scotch.*) The stone-breaker's hammer.

Knap'sack. A soldier's or tourist's case or wrapper for clothes, etc., to be carried on the back during a march. See ACCOUTERMENT.

A tourist's or traveler's satchel. That shown has a pocket *A* and strap *B*.

Fig. 2757.



Knapsack.

Knead'ing-ma-chine'. A machine for incorporating dough. It usually consists of certain stirring-blades and stationary arms, and a spiral blade for discharging the homogeneous dough.

The *pétrisseur,* or mechanical bread-maker, of Cavallier & Co., Paris, consists of a strong wooden trough, nearly square, with its two longest sides inclined. The bottom of the trough is semi-cylindri-

Digitized by Google

cal, and the ends support the axis of a cast-iron roller. A knife-edge is placed above the roller in a longitudinal position, and forms a practical division of the trough space into two semi-cylinders on the line of the axis of the roller. The roller being rotated, the dough is drawn between it and the bottom of the trough, which space is governed by lever adjustment. The knife-edge arrests it above; and when all has passed to one side the motion of the roller is reversed, when it is drawn back again. This is repeated until the materials are perfectly commingled and the quality uniform.

Another English *kneading-machine* has separate cells and heavy balls. A third has an agitator with a revolving axis and a series of rings angularly attached, and operating in a trough.

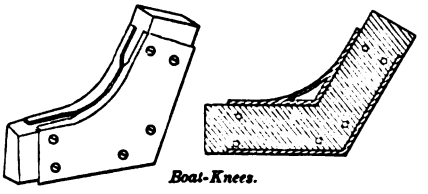
The *mixing-machine* of the ship-biscuit factory of the Victualing Department, Portsmouth, England, is a mixing-trough with a revolving axis furnished with two sets of knives, which mix 280 pounds of flour with 13 gallons of water in 2½ minutes. The *kneading-machine* is a cast-iron roller weighing 1,500 pounds, which rolls back and forth upon a bench, flattening out the slab of dough, which is again and again doubled and laid in the track of the roller. See BISCUIT-MACHINE.

Repeated passage between rollers, doubling the sliver between passages, is the ordinary mode of machine kneading. Harrison's biscuit-machine (English) operates thus (see BISCUIT-MACHINE), and so do the American CRACKER-MACHINES (which see). The hard-baked, unfermented cake called a *biscuit* by the French, English, and seafaring people generally, is a cracker among the landsmen of the United States, where it assumes many forms and is variously qualified as to ingredients, consistence, etc., *e. g.* sugar, water, butter, soda crackers.

Cracker-dough was formerly kneaded by an instrument called a *break*. It was a lever, pivoted at one end to a ring in the wall, and operating on a semicircular bench on which the dough was laid. The man who operated it was called a breakman, and brought his weight to bear on the lever, giving it and himself a dancing motion as the break traversed in its curved path, giving a succession of radiating impressions upon the slab of dough beneath it.

Knee. 1. (*Shipbuilding.*) A *compass-timber*. A naturally grown bent piece used to secure parts together, acting as a brace and tie. The *back* or outside bent portion is fayed to the parts to be united.

Fig. 2758.



Boat-Knees.

The exterior angle of a *knee* is the *breech*; the interior angle is the *elbow* or *throat*.

The *square* knee has a right angle.

The *knee without a square* has an obtuse angle.

The *knee within a square* has an acute angle.

The knee derives its specific name from its position, or the parts to which it is accessory, as, —

Cheek-knee; a compass timber at the head; also known as, —

Head-knee; a molded timber fayed edgeways to the cutwater and stem.

Hanging-knee; one fayed to the side, in a vertical position. The *knee up and down*.

Lodging or *deck-beam knees*; fayed to the side horizontally to secure the deck beams.

Dagger-knees, i. e. *diagonal knees*; fixed obliquely to avoid a port.

Standard-knee; one arm bolted to the deck, and the other against the ship's side.

The *carling-knee* is in the angle formed by the junction of a carling with a deck beam.

Heel-knee; a compass timber which connects the keel and stern-post.

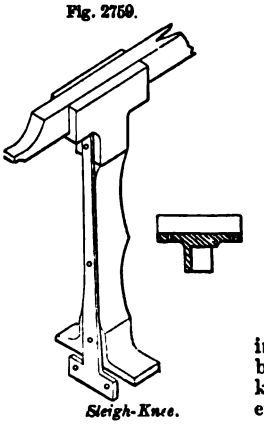
Transom-knee; *helm-post knee*, etc.

2. (*Carpentry.*) A piece of wood having a natural bend, or sawed to shape and fitting into an angle as a brace and strut.

3. An elbow piece which connects parts as that shown in Fig. 2759, in which the side plates are let into the pieces of timber and bolted thereto. The flanges lap around the edges.

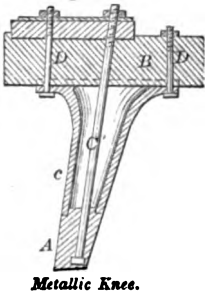
4. A piece framed into and connecting the bench and runner of sled or sleigh. It is usually mortised

Fig. 2759.



Sleigh-Knee.

Fig. 2760.



Metallic Knee.

into the respective parts, but in the example the knee is sunk in the sockets of the metallic blocks. Fig. 2760 shows a hollow metallic knee *c* secured by a straining-bolt *C* and screw-bolts *D* to the bench *B* and runner *A*.

5. An elbow or toggle-joint.

Knee-cap. (*Harness.*) A padded or leather cap secured by straps over the knees of racing, hunting, and other valuable horses when at exercise, to protect the part against abrasion in case of an accidental fall.

It is made of fabric, leather, caoutchouc, gutta-percha, compressed cork in a double pad, etc.

Knee-joint. A joint consisting of two pieces articulated endwise to each other, like the human knee. A *toggle-joint*. See TOGGLE.

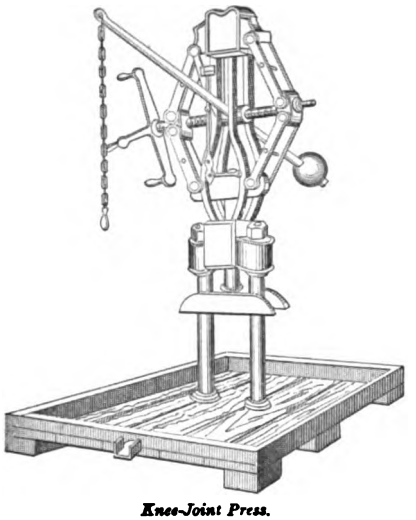
Knee-joint Press. One in which power is applied by means of a double knee-joint articulated at the top to the upright framework, and at the bottom to a cross-head, from which proceeds the shaft which applies the force, and which works through a guide. At the junction of the branches the articulations are made with masses of metal forming screw-nuts, through which passes a horizontal screw, right-handed for one half its length, and left-handed for the other half. This screw is operated at first by means of a set of crank-handles at one end of it; and when the resistance becomes very great, by means of a counterpoised ratchet lever, which is shown in the middle of the frame. The force applied in this way is very great, since the operator can act on the lever with his whole weight.

Knee-stop. (*Music.*) A lever operated by the knee to work the swell of a cabinet organ.

Knee-swell. (*Music.*) An arrangement in an

Digitized by Google

Fig. 2761



Knee-Joint Press.

organ by which a greater or lesser amount of wind may be turned on to the reeds to vary the loudness of the tone.

Knife. 1. A cutting-implement having a blade sharpened on the edge, and distinguishable from a sword, a colter, and other things, by its form and uses.

The earliest forms of knives are made of flints (*a, b, e, f, g*, Fig. 2762), and after the introduction of bronze (*c*) they were still retained for the performance of religious observances. This is shown by the use of a "sharp stone" in performing the operation of circumcision, as recorded in Exodus iv. 25, where Zipporah operated upon her child in conformity to the Jewish law. Herodotus says that an Ethiopic stone was used for making the incision in the body of persons brought to be embalmed, in order to remove the intestines. Diodorus Siculus says that "it was not lawful to use metal." In the Berlin Museum are two flint knives (*a, b*) of ancient Egypt, which, no doubt, were used in their religious observances; for the embalming of bodies was of this character, and was under the control of the priests.

c is the knife as represented in the Egyptian hieroglyphics.

d shows an old Egyptian butcher with his dismembering-knife, and his steel stuck into his belt.

e f g are from Assyrian knives in the British Museum.

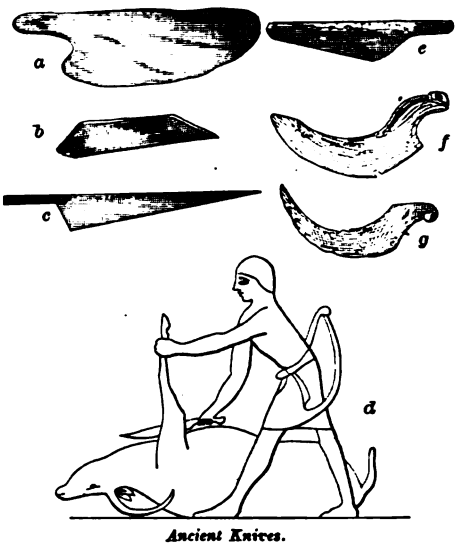
In the Egyptian museum of the late Dr. Abbott, New York City, are several of the Egyptian knives of Ethiopic stone. The operation of circumcision is now performed in Barbary with an ordinary pair of scissors.

The knives of ancient Egypt were usually of bronze, though blades of iron and steel were not unknown. Those of the latter metal have seldom, if ever, come down to our times, as they so readily rust and fall to pieces. They are, however, clearly distinguished from the bronze by being colored blue in the paintings of Byban el Molouk, the bronze being red or brown. Blue swords (steel) are shown in the paintings of Thebes.

These old knives had tangs like our case-knives, and for the same purpose.

Among the first mentions of knives is that of Abraham, who took his knife to slay his son on Mt. Moriah. The history of edge-tools would include the history of the knife, and would carry one back to the Lacustrians and other remote inhabitants of the globe. History opens with men using knives of metal, but still retaining the flint knife for sacrificial occasions, as in Egypt, Mexico, and among the Hebrews. Other isolated races contented themselves with shells, as among the Caribs; Obsidian among the Peruvians, Mexicans; flint in ancient Europe and many other places. The first metallic knives were made of copper, and these were afterwards hardened by the addition of tin, making bronze. From the time of Osirtasen and Jacob down to the time of the Cæsars and Pliny, bronze maintained its ascendency, but eventually gave way to iron and steel.

Fig. 2762.



Ancient Knives.

The Mexicans had no iron tools; the material was bronze or obsidian, known by them as *itztli*. Of this they made knives, razors, and serrated swords.

The knife of the Tahitians, previous to the advent of Europeans, was splinter of bamboo. All the tools of the islanders were of bone, wood, shell, or stone. Metal was unknown, and iron was at first supposed to be a very hard wood. The first nails they received were planted in the gardens, in the hope that they might sprout.

The pruning-knives of the Feejees, when first discovered, were of tortoise-shell on wooden backs. Their hoes were a bone from the back of a turtle, a plate of tortoise-shell, or an oyster-shell. With their tortoise-shell knives they dexterously cut up their *bakolo* (long pig), as they call a baked human carcass, to distinguish it from short pig, the swine, whose meat it is said to resemble.

Whittling is not a modern or merely American pastime: —

> "A Sheffeld thwitel bare he in his hose."
> CHAUCER.

Stow says that one Matthews on the Fleet Bridge was the first in England who made fine knives, and that he obtained an act, 1563, against the importation of foreign ones.

Clasp or spring knives came to England from Flanders, and were common in 1650.

In the manufacture of pocket-knives, a bar of

Digitized by Google

steel destined to furnish a number of blades is heated to redness. A length is cut off, and the forger speedily *moods* this, that is, shapes it roughly into the form of a pocket-knife blade. Another heating is then required to fit the end for being fashioned into the tang, and another before the operation of *smithing*, the last stage of which is the stamping of the mark of the thumb-nail to facilitate opening. The tang is then ground and the blade marked with the name of the firm. The slight bulge on the reverse side caused by this operation is removed by fire or the grindstone. The blade is then hardened by heating it to redness and then plunging it into water up to the tang. Then follows the tempering to a light straw color. After this the various kinds of blades undergo sundry grinding operations to fit them for being hafted. Twelve distinct processes have by this time been gone through, and many more are necessary before the knife is completely finished, although the number of hands which it has yet to pass through depends in a great measure on the finish to be given to the handle, and the quality of the blade.

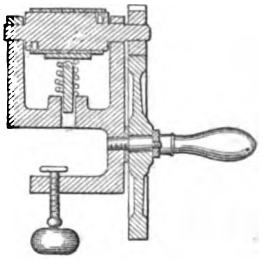
2. A blade in a machine, as in a *straw-cutter*, *rag-engine*, and what not.

Knife-board. (*Domestic.*) One with powdered bath-brick to clean knives upon.

Knife-clean'er. (*Domestic.*) An implement for cleaning knives. In the example, the frame is clamped by a set screw to a bench or table, and the cylinder is rotated by driving wheel and pinion; the guard holds a supply of polishing material, and the knife lies on a block which is pressed by a spring against the cylinder.

Fig. 2763.

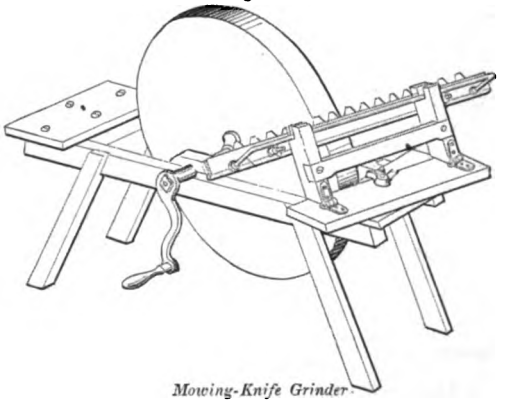


Knife-Cleaner.

Knife-edge. A sharpened steel edge resting against a horizontal surface, the two serving as a means of suspending a scale beam, or the scales from the beam, of a delicate balance, so as to obviate friction as much as possible.

Knife-file. A file with a very acute edge, the cross-section being an isosceles triangle with a short base. Known also as a *feather-edge* file. It is used

Fig 2765.



Mowing-Knife Grinder.

Digitized by Google

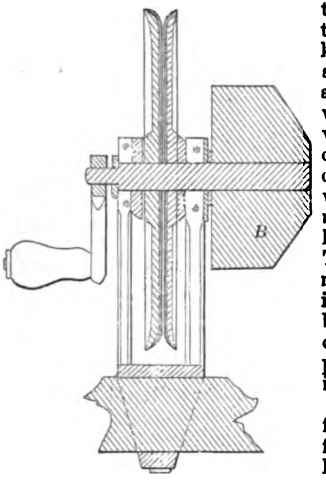
in cutting narrow notches, and in making an entering kerf for saws and for files with broader edges. Also in beveling or chamfering the sides of narrow grooves.

Knife-grind'er. 1. A grindstone or emery-wheel for grinding knives. See GRINDSTONE; EMERY-WHEEL; TANITE; LAP; GLAZER, etc. See list under GRINDING AND POLISHING.

2. A machine for special service, as in the example, which is a stone for grinding the knives of mowers and reapers. It has a holder set at such an angle with the frame, and also at such an inclination as to present the triangular knife-sections to the grinding face of the stone.

Knife-pol'ish-er. (*Domestic.*) A machine for cleaning the rust and stain from table-knives. In the example the knife-blade is slipped between a pair of disks, which are revolved by the crank. The disks are covered with a felted fabric, composed of linen and wool. The fabric is made by enclosing a linen bat between two bats of wool in the process of felting.

Fig. 2765.



Knife-Polisher.

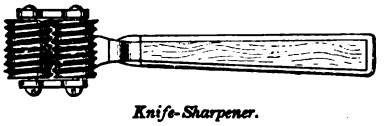
B is a bevel-faced grindstone for sharpening knives.

Knife-rest. A little pillow of metal or glass to rest the blade of a knife upon, at table. *Balance-handle* knives have rendered it unnecessary except with *carvers*.

Knife-sharp'en-er. (*Domestic.*) *a.* A steel.

b. An implement for sharpening table-knives by drawing them between two steel edges. In Fig. 2766 it consists of two screw-threaded rolls set in a frame, secured in a handle, and between which the knife is to be drawn.

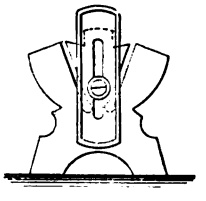
Fig. 2766.



Knife-Sharpener.

In Fig. 2767, there are two inclined jaws with a plate which crosses them obliquely. The middle plate is adjustable between the oblique side slots, and forms one side of each cutting jaw.

Fig. 2767.



Knife-Sharpener.

Knife-tool. A graver shaped like a knife.

Knight. (*Nautical.*) A wooden block with a sheave abaft the fore or the main masts, and known respectively as the *fore*-knight and *main*-knight.

Knight'head. (*Shipbuilding.*) One of the first *cant*-timbers on each side of the stem, which rise obliquely from the keel and pass on each side of the bowsprit, to secure its inner end.

Knit'ting-burr. A wheel having wings arranged radially and diagonally across its face, and adapted to operate upon the yarn and the fabric. There are several kinds, as follows: —

A *loop* wheel, whose wings are notched, and which take the yarn delivered by the guide, and push it up under the hooks or beards of the needles. A *sinker* wheel, which presses the yarn into loops between the needles, to insure that there shall be enough to form the proper-sized stitch in the fabric. A *landing* heel, which raises the loops of the fabric a short distance above the points of the needle-beards while they are closed by the *presser*. And a *stripping* or *knocking-over* wheel, which throws the loops of the fabric entirely over the tops of the needles to complete the stitch. See KNITTING-MACHINE.

Knit'ting-gage. The number of loops contained in three inches of breadth.

Knit'ting-ma-chine'. The art of knitting is modern; it cannot be traced back farther than about A. D. 1500, and is believed to have originated in Scotland shortly previous to that date. It consists in the construction of a looped fabric in which for the first row a succession of loops are *cast on* or preferably *knitted on* to a needle, and in succeeding rows each loop is passed through the loop of each succeeding row. It differs distinctly from *braiding*, *netting*, and *weaving*, which is, perhaps, the order of invention; *knitting* being scores of centuries later than either of the others.

Braiding is synonymous with *plaiting*, and is found among the most barbarous nations; none so ignorant that they cannot plait strips of hide or of bark, or braid a number of vines together to make a band. This is one degree of advance upon what nature provides them ready made, a rope of twisted tendrils or vines which, in reaching after a support, have mutually embraced and climbed upward. The natives of Tahiti, when discovered by Cook, were very skillful in making mats, which were plaited so as to resemble a woven fabric, and in other countries such are farther embellished by tufts. The process of making, however, was not by *warp* and *weft*, — was not *weaving*, — but was by braiding or plaiting a given number of strands arranged on two sides of a square, like the crosses we used to make of strips of differently colored papers when at school.

Netting is quite another matter, and is a fabric whose meshes are made over a mesh-stick and knotted at the intersections; as Dr. Samuel Johnson learnedly defines: "Network. Anything reticulated or decussated at equal distances, with interstices between the intersections."

The width of the mesh-stick determines the size of the meshes, which are knotted upon it. References to netting are frequent in the Hebrew chronicles, the Book of Job, the Prophets, in Homer, Virgil, and elsewhere. Oppian distinguishes many kinds. They are frequently shown in the Egyptian tombs and temples. See NET.

Weaving involves a machine, though this is sometimes of an extremely simple kind. It involves a beam or a means of stretching out the yarns into a flat row; also some means of dividing the yarns into a series above and one below, the space between being the *shed* into which the weft is laid; the upper and lower sets of yarns, changing places, lock the weft, and form another shed for a second weft thread, and so on. See LOOM; also, for list of parts and appliances, see WEAVING.

Digitized by Google

Knitting consists in making a fabric by enchaining a single thread. It is thought to have originated in Scotland about A. D. 1500. It was in use for superior articles of hose in England and France in the first half of the sixteenth century. Knitted silk stockings were worn by Henry II. of France, 1547, and by Queen Elizabeth in 1560. About this time knitted worsted stockings were made by William Rider of London, after the pattern of some imported from Mantua. Silk and worsted stockings were imported from Spain and Italy into England during the reign of Henry VIII. Spain was always famous for its sheep and wool. (See MERINO.) In 1530 the word *knit* was common in England, and occurs in Palgrave's grammar. In 1577 the country folks knitted their own stockings.

In 1589, William Lee, M. A., of Cambridge, England, invented and made a model of a knitting-frame. He applied to Elizabeth for help, and then to Henry IV. of France, who promised it. The assassination of Henry threw him into poverty and obscurity, in which he died. His workmen, with their stocking-frames, settled in Derbyshire and started a factory, which soon threw the hose of woolen cloth and leather entirely out of the market. Queen Elizabeth refused a patent to William Lee on account of the value of his invention; as it would interfere with the employment of a great number of her subjects, and to make the stockings for a whole people was too large a grant for any individual. About the same style of remark as was urged by Jefferson against one of Oliver Evans's patents, the "hopper-boy," so called.

Cotton stockings were first made by hand about 1730. The Derby ribbed stockings were patented by Jeremiah Strutt, in 1759.

The knotter frame patented by Horton, 1776.

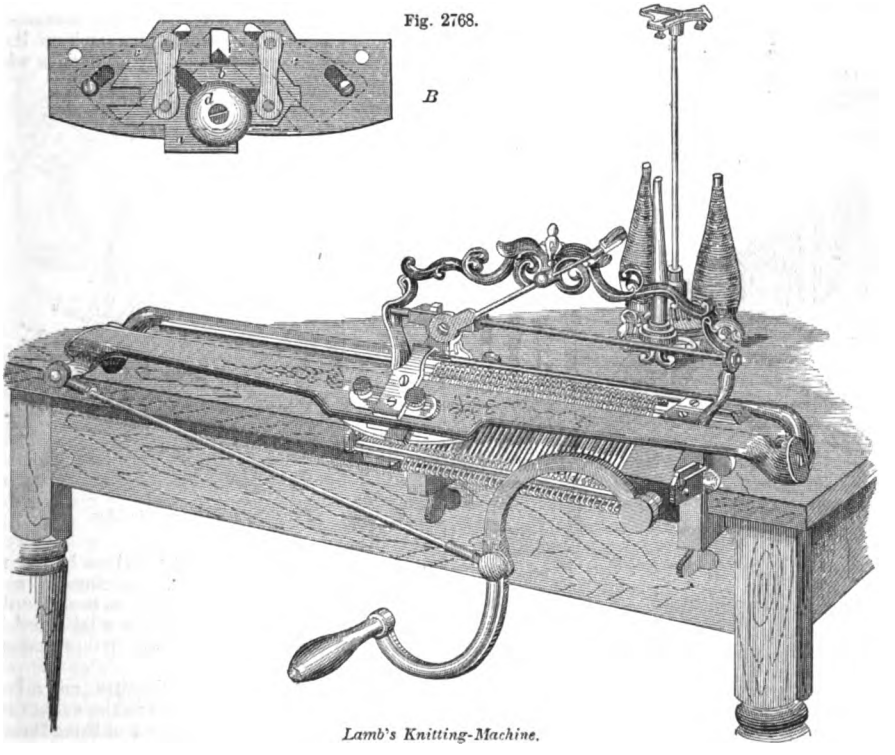
Of a Chinese village called "the old Duck," the Abbé Huc writes: "What struck us most in this place was that the art of knitting, which we had imagined unknown in China, was here carried on very busily; and, moreover, not by women, but by men. Their work appeared to be very clumsy; the stockings they made were like sacks; and their gloves had no separation for the fingers. It looked very odd, too, to see moustachioed fellows sitting before their doors spinning, knitting, and gossiping like so many old women."— *Travels in Tartary.*

Lamb's knitting-machine (Fig. 2678) is given as an example of that class which employs straight rows of needles in contradistinction to the machines using a circular system of needles, and to the single-needle machine. In the Lamb machine, a tubular web is produced by the operation of two straight parallel rows of needles, widening and narrowing being accomplished by increasing or diminishing the number of needles in action.

The frame is attached by thumb-screws to the edge of a table, and has its two upper sides inclined towards each other, their upper edges being separated far enough to allow the fabric produced to pass down between them. Supported by the needle-bed is a carriage, reciprocated by means of a crank. Through the arch that passes over the top of the machine is a horizontal rod upon which moves a slide that carries the guide for delivering the yarn into the hooks of the needles. Parallel grooves or channels are cut across the bed in which the needles are placed. In these grooves the needles can be moved their entire length, and can thus be brought into operation for widening, or thrown out of operation for narrowing, without removing them from the machine.

The needles employed are self-knitting, being constructed in such a manner that when fed by the yarn and carried an inch forward and back they form the loops by their own action. The lower ends of the

Fig. 2768.



Lamb's Knitting-Machine.

Digitized by Google

needles have an upright shank, extending above the face of the needle-bed, and are operated upon by cams that are attached underneath the center of the carriage in such a manner as to move the needles forward and back. There are two sets of these cams, one for each row of needles.

B is a representation of one of the sets of cams, which consists of the plate *a*, the two wing-cams *c c*, and the V-shaped cam *b*, which is held in place by the screws that pass through the washer *d*, in the diagonal slot of the plate *a*. As the carriage to which these cams are attached is drawn back and forth over the needle-bed by the crank, the needles are carried up on one side of the V-shaped cam in the groove or space between that and the wing-cams, the yarn-guide at the same time delivering the yarn into the hooks of the needles, which are then drawn down by the wing-cam on the other side of the V-cam, thus forming the loops.

The slide *a* is made to shift by its lower projection coming in contact with adjustable cam-stops, that are placed at the ends of the needle-bed. When the plate comes in contact with the right-hand cam-stop, the screw through the washer *d* is forced up the diagonal slot, and brings up the V-shaped cam, thus closing the space between it and the wing-cams. When closed, the needles pass below the cam without operating. By the adjustment of the cam-stops either or both of the cams may be left open or closed at the same time, so as to operate the two rows of needles separately, alternately, or together; thus forming three entirely distinct webs, — tubular web, plain flat web, and ribbed flat web.

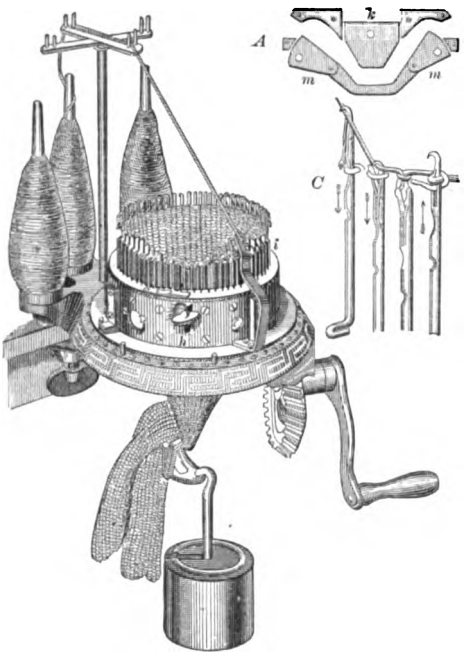
As any number of needles can be moved up at the start, or be moved up or down at either end of the rows of needles at any time, so any size of web can be set up and any number of loops can be added to or taken from it at will. By thus knitting the fabric, either tubular or flat, plain or ribbed, in any desired shape, a great variety of staple and fancy-knit goods may be produced.

The loops are formed on precisely the same principle as in hand-knitting.

The Bickford knitting-machine (Fig. 2769) is a specimen of the circular system. A bed-plate having a vertically projecting and grooved needle-guiding cylinder or bed *i* is secured to a table or suitable support. On the bed-plate is a loose ring, provided with a thread-guide for conducting the thread to the needles, and about the needle-cylinder is a revolving cylinder *h* having an annular groove interrupted by a cam portion (see *A*) and provided with adjustable cams *k m*, which govern the downward motion of the needles, and consequently the length of the loops, and raise the needles; and two of these latter cams are needed to provide for reversing the machine for knitting the heel or a flat web. The cam-cylinder is moved by a bevel gear connected to a driving-crank, and when moved continuously in one direction knits a circular web; and this web may be narrowed as desired to fashion the leg by removing needles, and placing their loops on adjacent needles. The needle on the left, at *C*, is receiving the thread within its hook, and it is subsequently moved by the cam-cylinder into the positions shown to form the thread so taken into a loop. When the heel is to be formed, a portion of the needles are drawn up, thus retaining their loops, and the number of needles left in action correspond with the width of the heel to be formed. The cam-cylinder is now to be reciprocated in opposite directions, and in order to keep the thread-guide in advance of the descending needles sufficiently far, so that the thread will be caught, pins are inserted in the bed-plate, and engage the heel of the thread-carrier, and stop it just before the cam-cylinder is stopped.

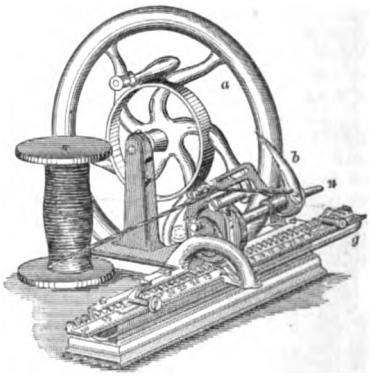
Fig. 2770 is an example of what is known as the single-needle machine. The loops are formed and held on the teeth of a comb, which is moved along, one tooth at a time, by means of a rack on its rear side, whose teeth are engaged by a fin on a wheel *c*

Fig. 2769.



Bickford Knitting-Machine.

Fig. 2770.



Hinckley's Knitting-Machine.

on one end of a shaft *n*, that is driven by the main wheel *a*, one part of the fin being movable, so that it can be swung from side to side, to vary the direction of the motion of the comb by a tri-armed lever located in the wheel *c*, and which strikes one or the other of the movable stops *g*.

A single needle *b*, carrying the yarn, and a looper, are used, the former being shown in the cut as thrown up out of operation, for the purpose of being threaded.

Digitized by Google

When in operation, it reciprocates in an arc under the comb, the slot in its actuating arm engaging a crank-pin on the side of the wheel *c*. The looper reciprocates in an arc above the comb, a pin in its actuating arm projecting into a groove in the side of the wheel.

The needle and looper being in their rearmost position, and there being a loop on each tooth of the comb, the needle advances under the comb and through one of the loops, which it removes from the comb and holds a while. The looper then advances above the comb, and its point enters between the yarn and the side of the needle. The needle then recedes, leaving its yarn in the form of a loop on the looper, and dropping the old loop, and the looper also receding, deposits its loop on a tooth of the comb, the latter being then moved forward one tooth for the formation of the next loop in the same manner.

Fig. 2771 is a machine of the ordinary circular kind, and produces a plain tube. The needles are bearded and fixed around the periphery of a rotating cylinder. They have no endway motion, but the stitch is formed as follows, it being assumed that there is already a row of them upon the needles and near their lower ends. The yarn delivered through the eye in the end of the guide *a* is taken and

B, Fig. 2771, shows a piece of ordinary knitted goods with loops distended.

Fig. 2772 is a machine of the kind which produces a plain, flat strip of fabric; it is an ordinary straight machine, and operates as follows: —

Fig. 2772.

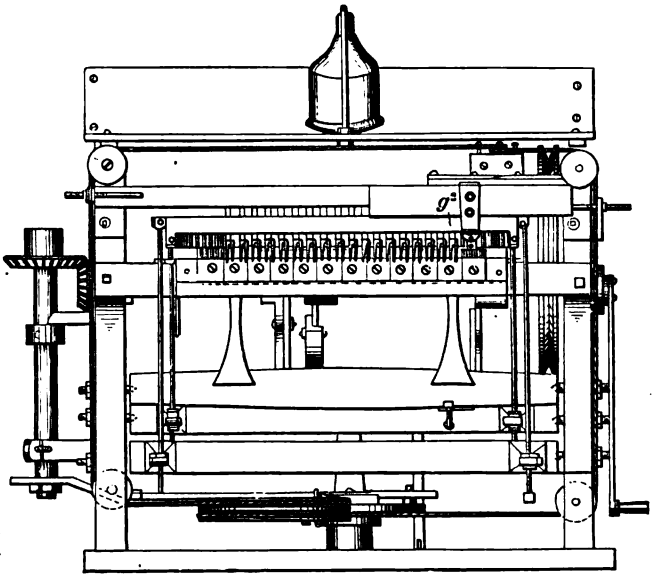


Fig. 2771.

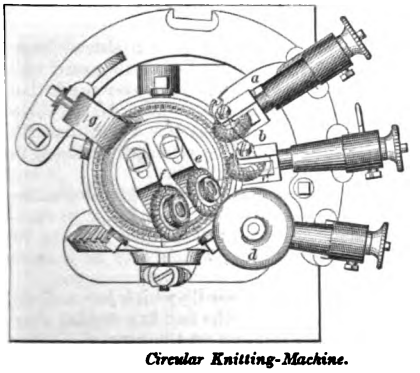
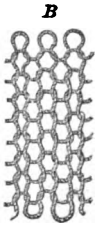
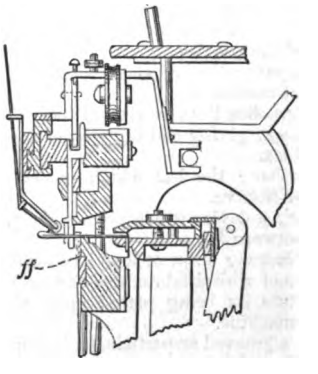


Circular Knitting-Machine.





Flat-Web Knitting-Machine.

pushed by the notched wings on the *loop-wheel b* up under the beards of the needles. The wings of the next or *sinker wheel c* then press the yarn in between the needles to insure that there shall be a sufficient quantity to form the proper-sized loops. The needle-beards are then pressed in, so that their points enter a depression in the stems, by the *presser-wheel d*, the yarn being thus inclosed between the beard and the stem, the old loops being at the same time raised, by the *landing-wheel e*, a short distance above and outside of the points of the beards. The *stripping* or *knocking-over* wheel *f* then throws the old loops entirely over the tops of the needles, and the fabric, with the newly formed row of loops, is pressed down to the lower ends of the needles by the curved cloth-presser *g*.

The meshes being in their extreme forward position, and the last-formed row of stitches being near their rear ends, the guide g^2 moves along the front of the machine, laying the yarn on the stems of the needles. The sinkers *c* are at the same time depressed, one after another, by the cam or *slur* above them, and depress the yarn into loops between the needles, which latter are then drawn slightly backward so that the yarn may pass under their beards. The presser-bar then descends upon and closes the beards, which then enter the old loops of the fabric, and the sinkers are raised in a body by the lifting bar in their rear (shown below in the sectional view). The needles receding to their extreme backward position, the old loops are thrown over their heads by being drawn against the plates *ff*. As

Digitized by Google

the needles move forward, the sinkers are all depressed in a body in front of the fabric, by the bar in front of the sinkers, to keep the loops back on the needle-stems. The needles then move entirely forward, and the looping operations are repeated.

The following are the technical names of the parts employed in knitting-machines: —

Beard; a long flexible hook on the upper end of the needle, and over and under which the yarn is moved to form the loop or stitch.

Dividing (or *bar*) *sinkers;* sinkers placed intermediate of the *jack-sinkers*, and which, after the jack-sinkers have operated, descend in a body to divide the yarn into proper-sized loops between the needles.

Fashioning-needle; one of a series, placed at each or either end of the row of needles, which are brought into or thrown out of operation to *fashion*, that is, widen or narrow the fabric.

Jack; a lever connected directly to and operating the sinkers.

Knocking-over bar; the bar against which the loops and fabric are drawn as the needles retreat, so that the loops shall be thrown or knocked over the heads of the needles.

Latch; a pivoted piece on the shank of a needle, and which swings forward to cover the hook and allow a loop to pass over its head, or back to uncover the hook, so that it may receive yarn to form a new loop.

Latch-opener; a device operating between the latch and the hook of the needle to throw back a closed latch, so that the yarn shall be surely laid under the hook.

Lead; a block of lead cast around and holding the shanks of two or more needles.

Point-shifter, or *tickler;* a pointed instrument which takes a loop from one needle and transfers it to another for narrowing the fabric.

Presser; a device which closes or depresses the beards of the needles.

Presser-bar; the bar which carries the presser in a straight machine.

Shifter. See POINT-SHIFTER (*supra*).

Shogging; giving endway motion to a bar carrying yarn-guides.

Shifter-bar; the bar which carries the *shifters*, *points*, or *ticklers*.

Sinker; a device which presses the yarn down on to and between the needles.

Slack course; a row of long loops made at the end of a piece of ribbed fabric (a sock-top, for instance), to facilitate its being placed upon the needles of another machine.

Sley; a grooved or partitioned bed or bar in which the needles or sinkers slide.

Slur-cock; a cam which depresses the sinkers.

Spring take-up; a spring-actuated device which bears against the yarn to prevent slackness.

Thread or *yarn guide* or *carrier;* a device which delivers the yarn or thread to the needles.

Tickler. See POINT-SHIFTER (*supra*).

Welt; a portion of the knit fabric turned over on itself and fastened down, to prevent raveling; resembling a hem in woven fabrics.

Work-roller; the roller upon which the finished fabric is wound.

Besides these are some other terms, some local, probably, some synonyms: —

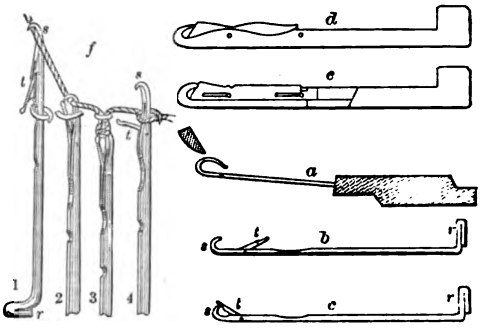
Beater.	Hook.	Neck.
Bowl.	Knock-off.	Shifter.
Catch-bar.	Jack-sinker.	Slur
Clawker	Latch-closer.	Warp roller-reel
Fly.	Lifting-bar.	Wiper.

Knit'ting-ma-chine' Jack. (*Knitting-machine.*) One of the set of horizontal levers, to whose ends the *jack-sinkers* are suspended. The *jacks* are moved in succession by a *slur*, which traverses beneath their points, thus moving in consecutive order the jack-sinkers which depress the loops between the needles.

Knit'ting-ma-chine' Nee'dle. The hooked member of the machine which passes through a previously made loop catches the yarn, and retreats through the loop, bringing the bight of the yarn with it, forming another loop. The essential feature of a knitting-machine needle is that it shall catch and draw the yarn to form the loop, and shall cast it off by allowing it to slip over, at another period of the action. The devices for this purpose are flexible beards and latches.

a (Fig. 2773) shows the English knitting-machine needle, which has a hook at one end with a pliable barb, which bends down into a groove in the shank when depressed by a presser-bar. The barbed hook

Fig. 2773.



Knitting-Machine Needles.

then becomes a closed eye; and if a thread looped over the stem of the needle be drawn forward while the barb is thus closed, it will pass over the barb of the needle and come off at the end. If the thread be drawn forward while the barb is open, it will be caught under the hook. The principal action of the machine depends upon this feature.

b c show two positions of the *latch*-needle: one with the latch lying back, the hook being in condition to catch the thread; the other showing the hook closed by the latch, which acts as a mousing.

d e are two views of a needle which has a closing slide. The lower view of the two is a section showing the slots which traverse on the pins.

f shows a group of needles with the yarn looped thereon, as when the machine is at work. The needle employed is shown complete at 1. In the other numbers a portion of the lower part is broken away. The needle consists of a body, an angular bent portion or foot *r*, a hook *s*, and a latch *t*. The latter is pivoted to the body of the needle, and works partly in a slot formed in the body. The latch has, moreover, a spoon-shaped end, which, when the latch is closed, as shown in needle 2, meets and partly shuts over the point of the hook *s*, so that the loop formed on the needle easily slips off when the latter makes its downward movement. The needle 1 has passed up through a loop of the previous row, and the hook *s* has caught the yarn; the mousing-latch is thrown back, as shown also at *b*, same figure. The needle 1 descends, drawing with it the yarn, as shown at 2, the position of the previous needle; the loop on the

Digitized by Google

shank has come against the latch *t*, and closed it against the point of the hook, so that the hook and its yarn slip through the loop, which is cast off, as shown at needle 3. Presently the needle commences to rise again, as its turn of work recurs, and, as it does so, as shown at needle 4, the loop lying in the hook slips down the shank, capsizes the latch *t*, and falls over it into the depression in the shank, as shown at needle 1. This is one round of work for a needle. Knitting by machinery is a rapid repetition of these motions.

Knitting-machine needles are made in machines by which the wire is reduced. In Aiken's machine the blanks are clamped in the arbors and brought singly between the grooved rest and rotating cutter, and are reduced by the cutter, which turns in a longitudinal plane, the arbors rotating meanwhile. After the blank has been reduced, it is drawn back from between the rest and cutter, the arbor-wheel is unlocked from the spring detent-pin, and another blank brought into position.

In another machine, for making the tongues of knitting-needles, the machine first forms the bowl and nick of the tongue, and simultaneously forces back the feeder upon the wire. The wire is then moved between the flattening dies; it is then moved to the punching dies, then to the dies rounding the end next the hole. The tongue with the sharp piece projecting from it is then cut off.

Knit'ting-nee'dle. A plain wire with smoothed ends, used in pairs in hand-knitting of flat goods and in fours for tubular work.

Knit'tle. 1. (*Nautical.*) A small line composed of two or three yarns laid together and twisted with the finger and thumb against the twist of yarn. Used for miscellaneous purposes on board, such as seizings, lashings, hammock-clues, pointing, grafting, etc.

2. A *draw-string* of a bag.

Knob. 1. (*Glass.*) The boss or central bulb of a *table* of glass when cut for use.

2. The handle on the spindle of a lock or latch.

3. A rounded handle of a door, lock, drawer, etc.

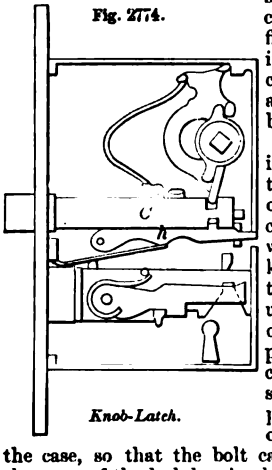
4. (*Architecture.*) A *knop*, bunch, or boss.

5. (*Ordnance.*) The cascabel of a gun.

Knob'bing. (*Masonry.*) The rough dressing, or knocking off the projections of stones in the quarry.

Knob'bling-fire. A sunken refining hearth, of small size, in which crude or partially refined iron is worked into a ball or *knob* in contact with charcoal and under influence of blast. A *bloomary*.

Fig. 2774.



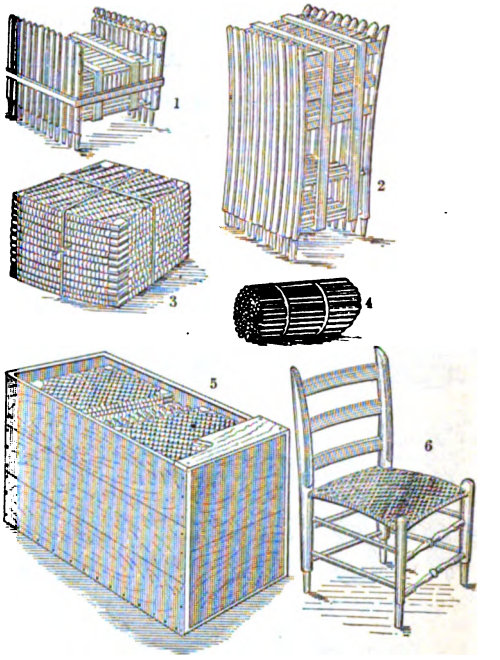
Knob-Latch.

Knob-latch. One in which the bolt is retractable by the knob or rotary handle, in contradistinction to one which is moved by a key. In the example, the latch-bolt *C* rests upon a horizontal bar *h*, one end of which is pivoted to the lock-case, while the other, supported by a spring, protrudes through an opening in the edge of the case, so that the bolt can be disengaged from the arms of the hub by simply depressing the end of the bar.

Knock-down. A piece of furniture or other structure adapted to be disconnected at the joints so as to pack compactly.

The *shook* may be said to be a knock-down barrel. The example shows the parts of chairs down,

Fig. 2775.

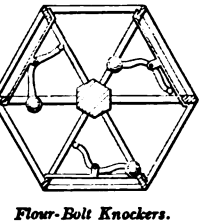


Knock-down Chairs.

bundled, and tied. The different figures show respectively a dozen front legs and rounds, as many backs, seats, side rounds; also a chair complete and box to hold a dozen knocked down.

Knock'er. 1. An attachment to an exterior door of a house, to give notice to those within that some one stands without.

Fig. 2776.



Flour-Bolt Knockers.

2. An attachment in a flour-bolt to jar the frame and shake the flour from the meshes of the bolting-cloth. In the example, the knockers are pivoted weighted arms; as the bolt revolves, the weights tilt the arms and strike the bolt-frame.

Knock'er-off. (*Knitting.*) A wheel with projections to raise the loop over the top of the needle and discharge it therefrom. A similar wheel, called a *sinker*, depresses the yarn between the needles. See BUR.

Knock'ing. (*Bookbinding.*) Setting even at the edges, by taking a bunch or pile of sheets or leaves and striking an edge on the bench.

Knock'ing-down I'ron. (*Bookbinding.*) An iron for pounding down the projecting twines (*slips*) to which the sheets are sewed, so that they shall not project and mark the back cover.

Knock'ings. 1. (*Metallurgy.*) The larger pieces of ore and gangue which are picked out of the sieve. The sorting of lead ore by the sieve develops

Digitized by Google

three qualities, *knockings*, *riddlings*, and *fell*. The former are large scraps, which are picked out.

The *riddlings* are what remain in the sieve.

The *fell* is the smallest, and falls through.

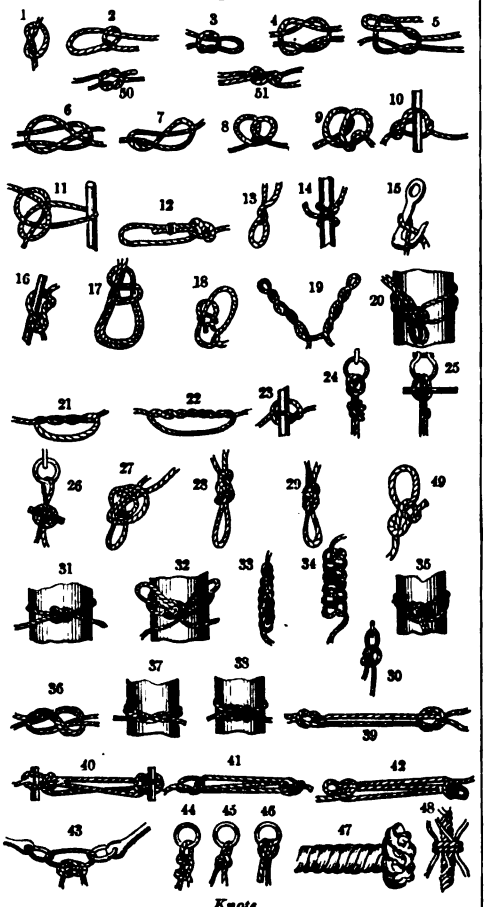
2. (*Masonry.*) The small pieces broken off from stone by hammering or chiseling. Large pieces are *spalls*.

Knock-off. (*Knitting-machine.*) The piece which, at the proper moment, removes the loops from the tier of needles.

Knock-stone. (*Mining.*) A block on which ore is broken.

Knot. 1. (*Nautical.*) *a.* A device formed by intertwining a rope or cord so as to attach one part of it to another part of itself, to another rope, or to any other object. The kinds of knots employed, especially by nautical men, are too numerous to admit of description, and we content ourselves with exhibiting a few of the more prominent.

Fig. 2777.



Knots.

1, simple overhand knot.
2, slip-knot, seized.
3, single bow-knot.
4, square or reef knot.
5, square bow-knot.
6, weaver's knot.
7, German, or figure-of-8 knot.
8, two half-hitches, or artificer's knot.
9, double artificer's knot.
10, simple galley-knot.
11, capstan or prolonge knot.
12, bowline-knot.
13, rolling-hitch.
14, clove-hitch.
15, blackwall-hitch.
16, timber-hitch.
17, bowline on a bight.
18, running-bowline.
19, catspaw.
20, doubled running-knot.
21, double-knot.
22, sixfold-knot.
23, boat-knot.
24, lark's head.
25, lark's head.
26, simple boat-knot.
27, loop-knot.
28, double Flemish knot.
29, running knot, checked.
30, crossed running-knot.
31, lashing-knot.
32, rosette.
33, chain-knot.
34, double chain-knot.
35, double running-knot with check-knot.
36, double twist-knot.
37, builder's knot.
38, double Flemish knot.
39, English knot.
40, shortening knot.
41, shortening knot.
42, sheep-shank.
43, dog-shank.
44, mooring-knot.
45, mooring-knot.
46, mooring-knot.
47, pigtail, worked on the end of a rope.
48, shroud-knot.
49, a bend or knot used by sailors in making fast to a spar or to a bucket-handle before casting overboard; it will not run. Also used by horsemen for a loop around the jaw of a colt in breaking; the running end, after passing over the head of the animal and through the loop, will not jam therein.
50, a granny's knot.
51, a weaver's knot.

Those shown are generally in open position, so as to more clearly explain the way in which the parts of the rope run previous to being drawn taut in order to join them together and prevent slipping.

Some kinds of knots are called *hitches* and *bends*, which terms usually indicate that they are chiefly employed for making the rope fast to another object, or for securing two objects together.

The principle of a knot is, that no two parts which would move in the same direction if the rope were to slip should lie alongside of and touching each other.

The *standing-part* of one rope and the *end* of the other should not lie side by side. This feature distinguishes the *sheet-bend*, *bowline-knot*, *carrick-bend*, *reef-knot*, etc., from the *granny's-knot*, *slippery-hitch*, etc.

b. A nautical or geographical mile; $\frac{1}{60}$ of a degree of latitude; about 2,025 yards. The English statute mile is 5,280 feet.

A *log-line* is a *knotted* cord, the distance between the *knots* being $\frac{1}{120}$ of a nautical mile apart, that is, 50 $\frac{7}{120}$ feet. The log line is allowed to run out for 30 seconds, which is $\frac{1}{120}$ of an hour, so that the distance between *knots* on the cord bears the same ratio to a degree that the time does to an hour.

Thus if 8 knots on the log-line run through the hand of the seaman while the sand in the $\frac{1}{2}$-minute glass is running out, it is an indication that the vessel is traveling 8 nautical miles per hour. See LOG.

2. (*Brush-making.*) The brush-maker's term for a tuft of bristles ready for insertion into a hole drilled in the stock.

3. So many skeins. See HANK.

Knot'ter. (*Paper-making.*) A sieve which detains knots in the pulp, so that they do not pass to the moving wire-plane on which the paper is formed. See PAPER-MACHINE.

Knot'ting and Stop'ping. 1. (*Painting.*) A process preliminary to painting, consisting of painting over the knots of wood with red-lead, and the stopping of nail-holes, cracks, and faults with white-lead.

A silver leaf is sometimes laid over the knots in superior work.

2. (*Cloth-making.*) Removing weft knots and others from cloth by means of tweezers.

Digitized by Google

Knout. The Russian whip for criminals and other offenders.

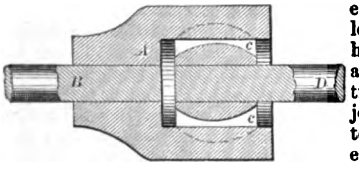
It has a handle 2 feet long, and a thong 4 feet long terminating in a brass ring. To the latter is attached the tail, 2 feet long, and running from 2 inches wide at the ring to a point. This is soaked in milk and dried to harden it. The tail is changed every sixth stroke.

Knubs. The offal or waste silk in winding off from the cocoon.

Knuck'le. 1. (*Mechanics.*) The joint-pieces of a hinge through which the *pintle* passes.

Knuck'le-joint. A joint in which a projection on each leg or leaf of a device is inserted between corresponding recesses in the other, the two being connected by a pin or pivot on which they mutually turn. The legs of dividers and the leaves of butt-hinges are examples of the true knuckle-joint. The term, however, has been somewhat commonly applied to joints in which the motion is not confined to one plane. Such are really universal joints, a form illustrated in the *ball and socket* and the *gimbal*. A *ginglymus*.

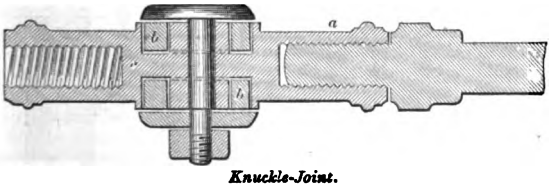
Fig. 2778.



Knuckle-Joint.

The example (Fig. 2778) differs somewhat in character from those just described. In this, designed for coupling the tumbling-rods of thrashers, and for other couplings which require play, the head of the shaft *D* has projections *c* which fit in corresponding grooves in the socket *A*, enabling the rods *B D* to be turned either to the right or the left, as desired.

Fig. 2779.



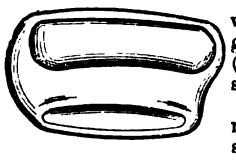
Knuckle-Joint.

In Fig. 2779 the rings *b b* are let into annular recesses in the arms *c a* of the two parts to be coupled, relieving the center-pin from all strain. See COUPLING.

Knuck'le-shield. One to save the knuckles in washing and scrubbing. The example shows one made of india-rubber.

Knuck'le-tim'ber. (*Shipbuilding.*) A top timber in the fore body, where a reverse of shape causes an angle on the timber.

Fig 2780.



Knuckle-Shield.

Knurl'ing. Providing with ridges to assist the grasp, as in the knurled (or milled) head of a set-screw.

Koff. (*Vessel.*) A two-masted, Dutch fishing-vessel, carrying a sprit-sail on each mast.

Kom'pow. (*Fabric.*) A strong, white linen of China.

Kreel. 1. A fish-basket of osiers.

2. A framework fish-trap.

Kris. A short sword of the Malays. A *crease*.

Krum-horn. (*Music.*) A old musical instrument resembling a cornet.

After a singular change of orthography, it is represented by the *cremona* stop in an organ.

Kus'si-er. (*Music.*) A Turkish musical instrument, having a hollow body, a skin covering, and five strings.

Kutch. (*Gold-beating.*) The packet of vellum leaves in which gold is placed to be beaten.

The package of gold-beater's skin in which gold-leaf is placed for the second beating is called the *shoder*.

After the second beating, the pieces are cut up and re-arranged in gold-beater's skin, the package being called a *mold*.

Ky'an-iz-ing. Named from Kyan, the inventor of the process (1832). To prevent the decay of wood, cordage, or canvas, it is saturated with a solution of corrosive sublimate in open tanks or under pressure.

The timber is prepared as follows: A wooden tank is put together so that no metal of any kind can come in contact with the solution when the tank is charged. The solution consists of corrosive sublimate and water, in the proportion of 1 pound of corrosive sublimate to 10 gallons of water as a maximum strength, and 1 pound to 15 gallons as a minimum, according to the porosity or absorption of the timber subjected to the process.

Oak and fir timber absorb nearly alike, but some other woods, such as beech, poplar, elm, etc., are more porous.

The period required for saturating timber depends on its thickness; 24 hours are required for each inch in thickness, for boards and small timbers.

The timbers, after saturation, should be placed under a shed or cover from the sun and rain, to dry gradually.

In about 14 days timber not exceeding 3 inches in thickness will be perfectly dry and seasoned, and fit for use. Large timbers will require a proportionate time, according to their thickness.

Some processes of similar import may be shortly stated.

In Bethel's process, creosote is employed and forced under heavy pressure into the pores of the wood. (1838.)

Robbins expels moisture by heat and then saturates with coal-tar, resin, or bituminous oils, at 325° Fah. (1865).

Blythe treats with steam combined with hydrocarbon vapor.

Burnett employs chloride of zinc in solution, under pressure. (1838.)

Boucherie used pyrolignite of iron. (1840.)

Payne, sulphate of iron. (1842.)

Margary, acetate or sulphate of copper. (1837.)

Van der Weyde, solution of silicate of potash.

Heinemann: boil wood in alkaline solution, and treat, under pressure and heat, with resin, carbolic acid, and tar.

Nicholson, tar and petroleum.

Behr, solution of borax.

Earl, protosulphate of iron.

Payen, superficial carbonization. See WOOD, PRESERVATION OF.

L.

La'bel. A placard or slip attached to an object to indicate contents, destination, or ownership. See BAGGAGE-CHECK, for instance.

1. Animal labels are of many forms : —

a. A metallic strip bent into a link-shape, the ends being passed through two slits in the ear. On the outside is shown the name of the owner or the number of the animal on the stock-book.

b. A plate secured by rivet to the ear.

c. A button is inscribed with the name of the owner and fastened to the ear by means of a locking plate, which enters the tubular shank of the button.

d. A tag attached to the horns, wool, mane, etc., to indicate ownership, class, prize, merit, etc.

2. A card or tablet attached to a bottle, jar, drawer, etc., by a chain, or placed in a panel.

One on a can of fruit or other vegetables. In one case, the whole series of customary contents are placed on the margin of the can, and the kind contained in the can is indicated by a mark.

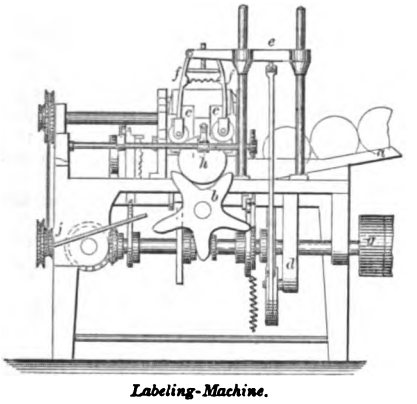
3. A brass rule with sights, formerly used in connection with a circumferentor to take altitudes.

4. (*Architecture.*) A molding over a doorway or window. A *head-molding* or *hood-molding* in the interior ; a *drip*, *drip-stone*, or *weather-molding*, on the exterior.

La'bel-cor'bel Ta'ble. (*Architecture.*) A corbel-supported head-molding over a doorway or window. Known also as a *drip-stone* or *hood-molding*.

La'bel-ing-ma-chine'. A device for attaching labels to cans, jars, or bottles. The example shows

Fig. 2781.



Labeling-Machine.

one form, in which the can is fed in at the chute *a*, and is taken up by the revolving star *b*. It is there retained in place long enough to receive the label from the gumming-wings *c*. The cam *d* gives downward motion to the cross-head *e*, and thence to the arms *f f* with the smoothing-rollers attached thereto. The can is then discharged by a partial revolution of the star *b* on to the chute *j*. Power is applied at *g*. The finger *h* holds the label in place while the gumming-wings return for another label. It takes in four sizes of cans, and has labeled 9,000 in ten hours.

Lab-i-dom'e-ter. A forceps with a measuring attachment for ascertaining the size of the fetal head.

Lab'o-ra-to-ry. 1. A house or apartment in which chemical experiments are conducted.

2. A manufactory of chemical articles.

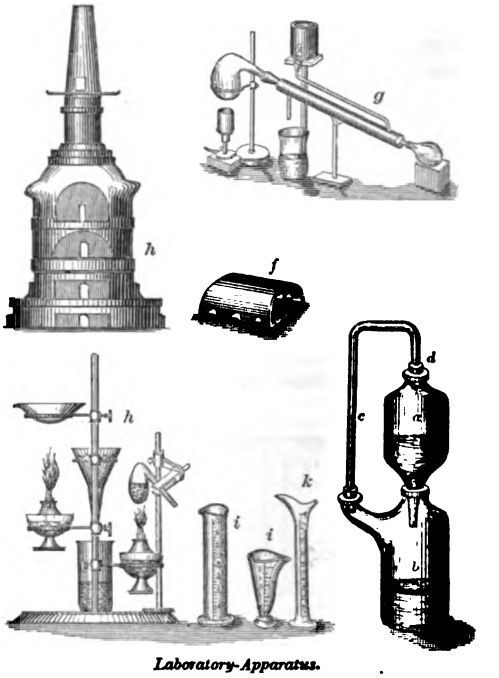
3. A place where fireworks are prepared.

4. A department in an arsenal where cartridges, fuses, primers, etc., are made, shells charged, etc.

Lab'o-ra-to-ry-ap-pa-ra'tus. Instruments and appliances used by the chemist in his study. Among them may be cited the cupellation-furnace *h*, cupel *f*, Liebig's condenser *g*, the retort and filter-stand *h*, measuring-glasses *i i*, pipette *k*.

A *filter* for chemical solutions, without access of fresh bodies of atmospheric air, is also shown in the figure ; the vessel *a* containing the solution and the

Fig. 2782.



Laboratory-Apparatus.

filtering-matter occupies the neck. As the liquid reaches the vessel *b* it displaces a body of air, which passes by the pipe *c* to the chamber *a*, entering through the stopple *d*, which is ground or provided with cork. See also BALANCE.

Lab'y-rinth. (*Metallurgy.*) *a.* A sinuous channel in which the ground ore (*slime*) and water are conducted, in order that the metallic portions may be deposited according to their respective gravities.

b. A chamber of many turnings in which fumes, derived from dry distillation of mercury, etc., are condensed. See CONDENSER.

Lac. A resin obtained from the *Ficus indica*. See RESIN.

Lace. A kind of network of threads of flax, cotton, gold or silver wire, or other suitable material, forming a fabric of transparent texture. Its origin is not known, but it appears to have been used by the ladies of ancient Greece and Rome. It was early used in Northern Italy, and is said to have been introduced into France by Mary de Medicis. In 1483 its importation into England was prohibited.

Digitized by Google

The systematic manufacture was introduced into England by refugees from Flanders.

Lace was anciently worked by the needle. The invention of lace *knitting* is attributed to Barbara, wife of Christopher Huttman, a German miner, in 1560. A manufactory was established in France by Colbert, in 1566.

Point lace was embroidered with the needle. *Bone* lace (temp. of Charles I.) was a kind of thread lace, and received its name from the bobbins being made of bone. About 1768, a stocking-weaver of Northampton produced a machine for making lace; it was called the *pin-frame*, and is still employed in France for making the lace called *tulle*.

The method of Barbara Huttman is as follows: The lace-maker has a hard cushion in her lap on which the pattern, traced on parchment, is laid, and pins passed through the parchment into the cushion at places determined by the pattern. She has also a number of bobbins on which the threads are wound, fine thread being used for the meshes or net. The work is begun by attaching the threads in pairs to the pins. The threads are then intertwined by means of the bobbins, so as to form the required pattern.

In *lace-weaving*, the threads of the weft are twisted round those of the warp. The manner of twisting determines the character of the net and its name,

Fig. 2783.

Lace-Weaving.

as *whip*-net, *mail*-net, *pattern*-net, *drop*-net, *spider*-net, *balloon*-net, *Paris*-net, *bobbin*-net.

The classification of laces at the English exhibition of 1851 was as follows: —

1. *Pillow-lace*, the article or fabric being wholly made by hand (known as *Valenciennes, Mechlin, Honiton, Buckingham*); or *Guipure* made by the crochet-needle; and *silk lace*, called *blonde* when white, and *Chantilly, Puy, Grammont*, and *black Buckinghamshire*, when black.

2. Lace, the ground being machine-wrought, the ornamentation made on the *pillow* and afterwards applied to the ground (known as *Brussels, Honiton*, or *appliquée lace*).

3. Machine-made net or quillings, wholly plain, whether warp or bobbin (known as *bobbin-net, tulles, blondes, Cambraie, Mechlin, Malines, Brussels, Alençon*, etc.).

4. Lace, the ground being wholly made by machine, partly ornamented by machine and partly by hand, or wholly ornamented by hand, whether tamboured, needle-embroidered, or darned.

5. Lace, wrought and ornamented by machinery, comprising *trimming laces* of every description, *veils, falls, scarfs, shawls, lappets, curtains*, etc.

The dates of some of the inventions connected with lace-making are as follows: —

Bobbin-lace invented by Barbara Huttman of St. Annaberg, Germany	1561.
Pillow-lace making taught at Gt. Marlow, England	1626.
Strutt's machine for making openwork stockings	1758.
Crane's Vandyke machine	1758.
Ere and Harvey's "pin" machine	1770.
Frost's point-net machine	1777.
Dawson's point-net machine	1791.
Heathcoat's bobbin-net machine	1804.
Hill's plain ground net machine	1816.
"Limerick" lace made	1829.

Laced-stock'ing. A bandage support for varicose veins, weak legs, etc.

Lace-mak'ing Ma-chine'. Lace is a delicate kind of network composed of silk, flax, or cotton threads, twisted or plaited together. See LACE.

The meshes are of an hexagonal figure, in which thick threads are also interwoven to form the pattern, according to some design; and these threads, which are called *gymp*, form the ornament of the lace.

The *point-net frame* was invented by Morris (England) in 1764, and is a variety of the stocking-frame, making a stitch or loop like that of a stocking, and formed by a continuance of one thread. The thread is by the machine formed into loops, a whole course at once, by pressing it down alternately over and under between a number of parallel needles. A second course is then made of similar loops on the same needles, and the loops of the first are drawn through those of the second in such a manner as to form meshes by retaining the first loops; the second are then retained by a third, and these by a fourth, and so on.

The *warp-net frame* is also a variety of the stocking-frame, but the parts are very differently arranged, the movements being produced by treadles, leaving the hands of the workman to manage the machine, which is a piece of mechanism applied in front of the row of needles of the frame. In the *warp-net frame* the piece of lace is not formed of one continuous thread, as in the *point-net frame*, but there are as many different threads as there are needles in the frame; these threads are *warped* or wound upon a roller or beam the same as a loom, and it is from this circumstance that the machine is called a *warp-frame*. These threads pass through eyes in the ends of small points, called *guides*, which are opposite the needles; and these guides are fixed on two bars, each of which has half the guides fastened on it; that is, one guide is fast to one bar, and the next to the other, and so on alternately of the whole. Each of the guides presents a thread to its needle, and all are at once moved by the hand to twist the threads two or three times round the needles that are opposite to them. The loop is now made in a manner similar to that in the *point-net frame*. The next time, the alternate guides are shifted endways, so as to apply themselves to other needles than those they were opposite to before; this crosses the thread so as to make a net, but the quantity that is shifted endways is changed every time by means of the machinery, so as to move a certain number of needles, which number is changed every time to produce the pattern.

The lace-making machine for weaving the real twisted lace, like that made on the pillow, was invented by Heathcoat, 1804.

The groundwork of the invention is to extend those threads which form the warp of the lace in parallel lines, and dispose the diagonal threads upon small bobbins, which are detached, and are capable of passing round the extended warp-threads so as to twist with them; by this means the number of bobbins is reduced to one half. In this machine there are two horizontal beams or rollers, one to contain the thread and the other to receive the lace; also a number of small bobbins to contain the thread.

Mr. Hebert thus enumerates the varieties of bobbin net-lace machines: —

The Loughborough double-tier	*Heathcoat's.*
The single-tier	*Stevenson's.*
The improved double-tier	*Brailey's.*
The improved single-tier	*Lever's.*
The Loughborough improved; with pumping-tackle.	
The pusher principle.	
The traverse warp	*Beran & Freeman's.*
The traverse warp, rotary	*Lindley & Lacey's.*
The straight bolt	*Kendal & Mauley's.*
The circular bolt	*Mauley's.*
The circular comb	*Hervey's.*
The improved circular comb	*Hervey's.*
The farther improved single-tier	*Lever's.*

Digitized by Google

Lace-pa'per. Paper having an openwork pattern and perforations made in imitation of lace. The process usually consists in grinding off the elevated portions of embossed paper, which is accomplished by passing the paper between two rollers, one of which is covered with ground glass or emery, the other is impressed with a duplicate of the design on the paper. The grinding-roller is made to revolve at high velocity.

Lace-piece. 1. (*Shipbuilding.*) The main-piece of the head, or beak-shaped projection from the *head* of a vessel. See MAIN-PIECE; STEM.

2. (*Nautical.*) The rope used to fasten a sail to its yard or gaff.

Lach'ry-mal-duct Di-lat'or. (*Surgical.*) A probe, by means of which the normal caliber of the nasal duct, in cases of obstruction, is restored. They are made of eight different sizes, of silver, lead, whalebone, hard rubber, and *laminaria digitata.* The silver is the most useful; whalebone and hard rubber are easy to guide, and less liable to injure the mucous membrane. The *laminaria*, after introduction, gradually swells up from imbibition of the tears, and thus dilates the canal.

Lac'ing. 1. A fastening by a cord, thong, or whang, which passes through holes prepared in the respective parts of the object so fastened. The term is applied to fastening up the front opening of some kinds of boots; also to the fastening together of the pieces which constitute a machine belt.

2. (*Bookbinding.*) Securing the book to the sides by carrying the bands or slips through perforations in the boards.

3. (*Nautical.*) The rope used to confine the heads of sails to their gaffs or yards.

Lac'quer. Primarily, a varnish composed of shellac dissolved in alcohol and colored by means of gamboge, saffron, annotto, and various other coloring matters. It is applied to wood, to papier-maché, and to metals to protect them from rust and improve their color. The term is also applied to compositions containing none of the above ingredients, they being replaced by turpentine, resin, etc.

The proportions of the shellac and alcohol vary. Two gallons of alcohol to one pound of shellac is probably the most common proportion.

Besides the coloring matters above referred to, turmeric, dragon's blood, gum sandarach, and red saunders are frequently employed in red and gold colored lacquers, the articles and their relative proportions being varied according to the tint desired. In the military service the following lacquers are used: —

For Small-Arms, or Water-Proof Paper.

Beeswax	13 pounds.
Spirits turpentine	13 gallons.
Boiled linseed-oil	1 gallon.

All the ingredients should be pure and of the best quality. Heat them together in a copper or earthen vessel over a gentle fire, in a water-bath, until they are well mixed.

For Bright Iron Work.

Linseed-oil, boiled	80.5
Litharge	5.5
White-lead, in oil	11.25
Resin, pulverized	2.75

Add the litharge to the oil; let it simmer over a slow fire three hours; strain it, and add the resin and white-lead; keep it gently warmed, and stir it until the resin is dissolved. For ordnance, shot, or shells, or other iron work not designed to be kept bright, coal tar thinned with spirits of turpentine forms a very cheap and permanent lacquer.

Lac-tom'e-ter. Called also galactometer. A species of hydrometer, graduated to show the comparative specific gravity and consequent value of different specimens of milk.

The instrument is a good evidence of the specific gravity of milk, and the specific gravity is a probable, but not positive, evidence of quality. Taken in connection with the per-cent glass, which measures the per cent of cream that rises, it is nearly a positive indicator of pure and watered milk.

One form of the *lactometer* for ascertaining the amount of cream in milk consists of a tube with a funnel mouth for convenience in charging it, and having the upper portion graduated. The tube is about a foot in length, and being filled the cream is allowed to rise, when its richness is determined by the number of graduated spaces occupied by the cream.

The hydrometer alone is not adapted to determine the amount of cream in milk, which can only readily be determined by test. Dr. Ure suggests it may be applied to the skimmed milk to determine the proportions of curds and whey.

Lac'to-scope. An instrument invented by Donne of Paris, for assisting in determining the quality of milk by ascertaining its relative opacity.

The "three times skimmed sky blue" of Bloomfield is the bottom of the scale, unless the pump-water milk for urban distribution is considered as zero.

Dingler's "Polytechnisches Journal" describes a simple apparatus for determining the richness of milk, as measured by its transparency. Two polished plates of glass are adjusted by means of a screw to stand at different distances from each other. The milk is placed between them, and the distance of the plates from each other when the flame of a stearine candle is rendered invisible, is the measure alike of the transparency and comparative richness of the milk.

Lac-var'nish. One made from shellac dissolved in alcohol. Colored by red, orange, or yellow matters. Lac is obtained from the *Ficus indica*, and the product is *stick lac, seed-lac, shellac*, and *lac-lake.*

Lad'der. 1. A frame — usually movable — having a series of steps attached to side-bars or ropes. The varieties are distinguished by their purposes, position, or by some feature of construction.

A *ladder* differs from a *stairs* in that the latter has *treads* and risers, being thus boxed in below. The *ladder* has merely *steps.*

Of the *nautical* ladders, we have, —

Accommodation-ladder.
Companion-ladder.
Forecastle-ladder.
Hold-ladder.
Jacob's-ladder.
Quarter-ladder.
Side-ladder.
Stern-ladder.

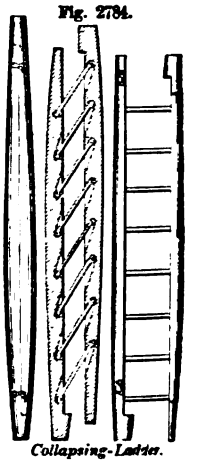
As to purpose, we have, —

Fire-escape.
Fire-ladder.
Fruit-ladder.
Garden-ladder.
Scaling-ladder.

The names denoting construction are, —

Chain-ladder.
Extension-ladder.
Rope-ladder.
Rule-joint ladder.
Step-ladder.

Fig. 2784.



Collapsing-Ladder.

Digitized by Google

The *collapsing-ladder* (Fig. 2784) has rounds pivoted to the side-rails, recesses in which receive them when the ladder is folded. When the side-pieces are drawn apart, the rounds assume a horizontal position.

A movable ladder is sometimes used in ascending and descending shafts. Two poles ascend and descend alternately, and have stages on to or from which the person steps from or to the corresponding step on the other pole, at the moment when they become stationary. See MAN-ENGINE.

Scaling-ladders are shown in the triumphal monuments of Rameses II., the great Sesostris, 1355 B. C.

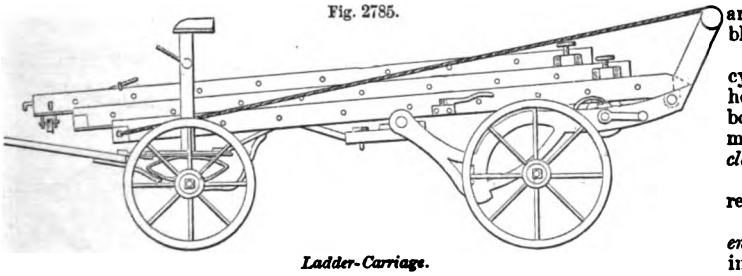
The first ladder of record was that seen by Jacob in his dream, and it is the longest and best of which we have any account. It is the only one mentioned in the Bible.

2. (*Nautical.*) The *accommodation*-ladder is a stairs slung at the gangway. The *forecastle* and *hold* ladders are at these respective places. The *Jacob's*-ladder abaft the top-gallant masts, where there are no ratlines at the shrouds. The *quarter* and *stern* ladders are for reaching or leaving the boats moored astern.

3. A notched cleat or stick in a bookcase, for supporting shelves.

Lad'der-car'riage. One for conveying fire-ladders. In the example, the bed-frame serves as a connection in coupling the wagon, and braces the ladder when raised. The windlass, having its bearings at the foot of the frame, extends the sliding sections of the ladder. The basket, attached by a rope to the pulley at the top of the ladder, forms a fire-escape.

Fig. 2785.



Ladder-Carriage.

Lad'der-way. 1. (*Mining.*) Or foot-way shaft. The shaft of a mine, by which the workmen ascend and descend.

2. (*Nautical.*) A *companion*-way or *scuttle*-way on board ship.

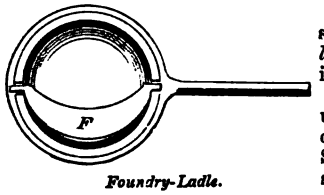
La'dies. (*Skating.*) A size of skates; 15 × 18 inches.

La'ding. (*Glass.*) The transference in cisterns of molten glass from the pot to the table, in plate-glass making.

La'ding-hole. (*Glass.*) An aperture in the side of a furnace for plate-glass, at which the *cuvette* for carrying the metal is introduced or is filled. See page 669.

La'dle. 1. (*Founding.*) A pan with a handle to hold molten metal.

Fig. 2786.



Foundry-Ladle.

On a small scale, the *bullet-ladle* is a familiar instance.

The large ladle used in the foundry is called a SHANKS (which see).

Ladles are protected by a thin coat or layer of loam, and every time, before being used, they are brushed over with black wash and carefully dried.

The example has a lunate-shaped plate *F* pivoted to the rim, and serving to keep back impurities floating on the metal.

2. (*Ordnance.*) An implement used for removing the shot when it is not wished to fire the gun. It is a semi-cylinder of copper, beveled at the end, and attached to a staff. For use, the muzzle of the gun is slightly depressed and the ladle passed in so as to run under the shot, which is received in it; when the ladle is withdrawn, it brings the shot out with it.

b. A cylindrical scoop of copper for loading loose powder into a cannon.

3. (*Pyrotechnics.*) A copper scoop for filling rockets.

4. (*Glass.*) A vessel in which molten glass is carried. A *cuvette.*

5. (*Domestic.*) A large dipping spoon.

6. (*Hydraulics.*) The float-board of a mill-wheel.

La'dle-board. A mill-wheel float.

Lag. 1. One of the boards or staves forming the covering of a large band-drum, or the upper casing of a carding-machine, or the covering of a steam-boiler or cylinder.

The *lags* of the drum are fastened by *lag-screws* to the frame of the wheel.

The *lags* of the carding-machine are *clothed* with *cards* on the under sides, and are separately removable.

The *lags* of the boiler or cylinder are wooden staves, hooped, and enclosing a body of non-conducting material. Otherwise called *cleading.*

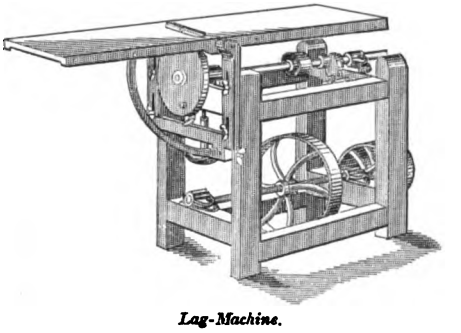
2. (*Steam-engine.*) The retardation of the valve.

Lag'ging. 1. (*Steam-engine.*) The non-conducting jacket or clothing of a steam-boiler or cylinder, to prevent radiation of heat. *Cleading, deading, sheathing, clothing.*

2. (*Carpentry.*) Narrow planks extending from one rib to another in the centering of arches and forming the board covering upon which the courses of voussoirs are laid.

Lag-ma-chine'. (*Wood-working.*) A machine for hollowing out the insides of *lags* or covering for wooden rolls or drums; or the *cleading* for jacketing cylinders or steam-pipes.

Fig. 2787.



Lag-Machine.

Lag-screw. A flat-headed screw used to attach lags to band-drums.

Digitized by Google

Laid. (*Paper.*) Paper having the marks made by the wires of the *deckle*.

The choice of coloring matter occasions the names *cream-laid, blue-laid*, etc.

Laid-on. (*Joinery.*) A term applied to moldings which are got out in strips and nailed on to the surface of the object.

Laid-pa'per. Paper made with a ribbed surface like that formerly made in the hand-frame.

Lam'bre-quin. 1. A curtain on the helmet to protect from the rays of the sun, like the cap with a valance named from the East Indian hero "Havelock."

2. A festooned drapery, forming an ornament at the upper part of a window, and covering the curtain rings and bar.

Lamb's Tongue. A plane with a deep, narrow bit for making quirks.

Lam'e-ro. A walled receiver, where the *slimes* (mud charged with auriferous or argentiferous particles, or both) are deposited from the arrastra, to part with a portion of their water, and accumulate till sufficient to form a *torta*, in which the amalgamation is performed. See AMALGAMATOR.

Lam'i-na-ted Arch. A timber arch made of successive thicknesses of planking bent on to a centering and secured together by tree-nails. See ARCHED BEAM.

The Ouseburn Viaduct of the Newcastle and Tynemouth Railroad, England, was erected on this principle. It is 108 feet high, and consists of 5 arches, each 116 feet span, and two stone arches at each end, 45 feet span.

Another bridge has 7 arches of 120 feet each.

Each arch has 3 segmental ribs, each of which has 30 deck deals, 3 inches wide, being 2 deals in width and 15 in height. The deals vary from 20 to 45 feet in length, and are laid so as to break joint. They are connected by oak treenails, each of which passes through 3 thicknesses. A layer of brown paper dipped in boiling tar is laid between thicknesses. The ends of the ribs are let into cast-iron shoes, which are fixed to the imposts of the masonry piers. The ribs are connected by diagonal braces and iron ties. The spandrels are strongly framed. All the wood-work was *kyanized*.

Lam'i-na-ted Pipe. Water, sewer, or gas pipe made of thicknesses of veneer or scale board successively wrapped to obtain thickness and strength. Each layer is thoroughly saturated with asphalt, and the grain of alternate layers passes in transverse directions, so as to secure an intimate bond and a line of resistance to disruption in any direction, lengthwise, oblique, or across the pipe circumference. The veneer is sometimes made to alternate with fabric or an adhesive composition.

Lam'i-na-ted Rib. An arched beam made of planks bent, laid flatwise in layers, and secured by bolts. See ARCHED BEAM.

Lam'i-nat-ing-ma-chine'. A gold-beater's rolling-mill for reducing the *ingot* of gold to such a thichness that a square inch will weigh 6½ grains. The ingot weighs 2 ounces, and is ⅜ inch broad. The rollers are of hard steel, and extend the ingot to a *ribbon*. The gold is frequently annealed during the process.

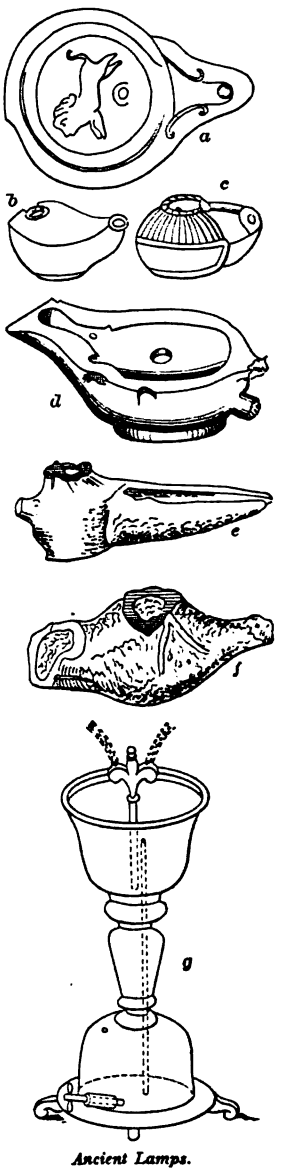
Lam'i-nat-ing-roll'er. (*Metal-working.*) One of a set by which a fagot or bloom is drawn out into a bar or sheet.

Lamp. A device in which an artificial light is produced by the burning of a wick saturated in oil or liquid fat.

Lamps were used before candles. The oil was conducted to the flame by means of a wick, before man learned to use the suet which hardened upon a wick and made a rigid rod of grease.

"The invention of artificial light has extended the available term of human life, by giving the night to his use; it has, by the social intercourse it encourages, polished his manners and refined his tastes, perhaps, as much as anything else, has aided his intellectual progress." — DRAPER.

Fig. 2788.



Ancient Lamps.

Lamps were used in early ages in all the ancient civilized countries, China, India, Egypt, Greece, and Rome. Many beautiful forms from these countries are to be found in collections: especially from the excavations of Pompeii. Sepulchral lamps were commonly placed in tombs, and have thus been preserved in many cases.

Homer makes no mention of them, though they had been long in use in Egypt, and it is understood that he had seen the Thebes he portrayed. The upper three figures, *a b c*, are representations of Egyptian lamps found in the tombs. The constellation Leo, shown upon the largest lamp, was *the* favorite sign in Egypt, for then Osiris (the Nile) came forth and embraced all the fertile land of Egypt even unto the desert, and retiring left the fertile deposit, from which sprung all the productions of the country.

d c f are ancient European lamps.

The Egyptians, according to Clemens Alexandrinus, were the first who used lamps in their temples. Green porcelain lamps were found in the great pyramids of Ghizeh and Sakkarah. The festival of Isis at Busiris was called the Feast of Lamps. The lamps had wicks floating in oil which rested on salt-water. They were used in the tabernacle and in the temple of the Jews.

In Hero's "Spiritalia," 150 B. C., is a description of a lamp (*g*) in which a supply of oil from a reservoir below is driven up by means of air introduced into the base by an air-pump. In another form of Hero's lamp, the oil is raised by water, introduced below the oil by means of a pipe.

"Al-mansúr first caused wax to be burnt in the interior [of the mosque of Cordova] in addition to oil, thus combining the effect of both lights." — Makkari's (Arabic) "History of the Mohammedan Dynasties of Spain."

For varieties, see under the following heads: —

Annealing-lamp.	Miner's lamp.
Aphlogistic-lamp.	Monochromatic lamp.
Argand-lamp.	Petroleum-lamp.
Astral-lamp.	Pump-lamp.
Carcel-lamp.	Safety-lamp.
Car-lantern.	Signal-lamp.
Clock-work lamp.	Singeing-lamp.
Davy-lamp.	Sinumbra-lamp.
Dobereiner's lamp.	Solar-lamp.
Electrical lamp.	Street-lamp.
Fountain-reservoir lamp.	Student's lamp.
Frost-lamp.	Submarine lamp.
Hydrogen-lamp.	Sun-burner.
Hydrostatic lamp.	Switch-lantern.
Lamp-stove.	Tar-lamp.
Lantern.	Vapor-burner.
Magnesium-lamp.	Vapor-lamp.
Mechanical lamp.	

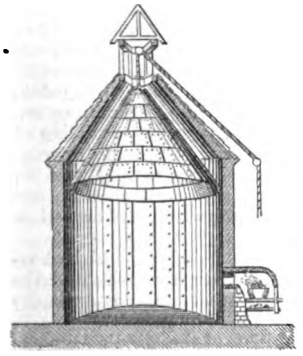
Lamp'black. A black pigment, consisting of pure charcoal, the particles of which are in a very fine state of division. It is principally prepared from refuse tar, resin, or turpentine, though it may be produced from a variety of other substances, animal and vegetable.

The tar, resin, etc., is burned in iron pots or a furnace, a quantity of air just sufficient to support combustion being admitted, in order to produce a dense smoke with little flame.

The smoke is let into cylindrical iron chambers, lined with sheepskin, woolen cloth, or canvas. Each chamber is provided with a roof fitting within it and suspended by a pulley and chain. This is lowered occasionally, scraping the lampblack from the sides of the cylinder, and depositing it on the bottom, whence it is removed through a small door by means of a hoe or scraper. A series of chambers may be used, communicating with each other by horizontal passages. In this case the roof of the last is partially open at top to permit a draft. The black deposited in this is the finest of all, but contains more or less resinous and oleaginous matter. This is removed by heating the black to a red heat in cast-iron boxes with close covers, and maintaining it at that temperature for two or three hours.

Ivory-black, largely used as a pigment, and bone-black, employed in refining sugars, are produced from animal bones. A bluish black, termed peach-black, is derived from the combustion of peach kernels.

Fig. 2789.

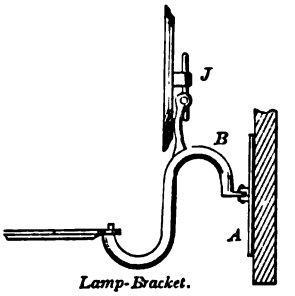


Lampblack-Furnace

Lamp'black-fur'nace. A cylindrical chamber lined with sheepskin or canvas, and having a conical top. The top is provided with a cowl through which the more volatile products of combustion escape, the carbon adhering to the lining of the chamber. At one side is a smaller communicating compartment provided with a grate, on which a vessel containing the hydrocarbon, resin, coal-tar, or similar substance, is placed, and heated by a fire beneath.

When a sufficient quantity of black has accumulated, a cone, having a small perforation at its summit, suspended within the main chamber, is lowered, scraping off the deposit accumulated on the lining, and causing it to fall to the bottom, whence it is removed by a suitable implement. In this state it contains resinous, bituminous, and other impurities, which are driven off by heating to redness in a close vessel, leaving nearly pure charcoal in an extremely comminuted state.

Fig. 2790.

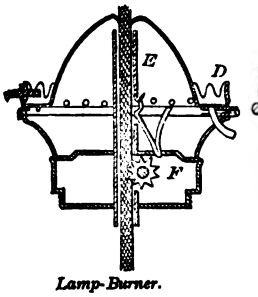


Lamp-Bracket.

Lamp-brack'et. A branch extending from a wall or pillar, to hold a lamp. *C* is the ring for the lamp-bowl, *K* the reflector which slips on the pin *J* of the bracket *B*, which is hinged to the plate so as to swing horizontally.

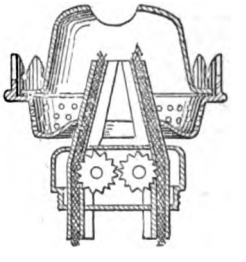
Lamp-burn'er. The portion of a lamp at which the wick is exposed and ignited. It has devices for adjusting the wick, and its crowning portion is usually such as to deflect a current of air upon the wick to insure a more perfect combustion. In the example, *F* is the wick-raising wheel, *E* the wick-tube, *D* the gallery for the flanged foot of the lamp-chimney.

Fig. 2791.



Lamp-Burner.

Fig 2792.



Double-Wick Burner.

In Fig. 2792 the wicks in the two curved tubes are raised simultaneously by two serrated wheels, which mash together. The air passes upward both within and outside the wick-tubes.

Lamp-ce-ment'. A cement for brass mountings on glass, such as on lamps, is made by boiling resin 3 with caustic soda 1 in water 5, thus making a kind of soap, which is mixed with half its weight of plaster of paris, zinc-white, white-lead, or precipitated chalk. It is unaffected by petroleum or similar burning-fluids.

Lamp-chim'ney. The glass funnel which increases the draft and protects the flame of a lamp.

L'Ange invented the lamp-chimney. He added it to the tubular wick and central air-tube of Argand's lamp, and perfected the invention.

Lamp-chimneys are usually of glass, but have been made of mica, metal with mica windows, horn, and porcelain. Their forms are various, from the straight cylinder of the German student's lamp to

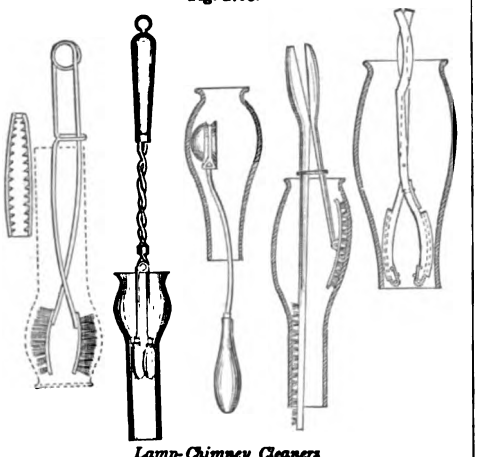
Digitized by Google

the obese bulb of commoner varieties. They have also been made in various convoluted and spiral forms, designed to give greater liberty of expansion with changes of temperature. They have also been split longitudinally, spirally, and made with holes, the intention being in each case to make them less liable to fracture by heat or a blow.

Lamp-chim'ney Ad-just'er. A means for raising and lowering a glass lamp-chimney in order to modify the draft, or to allow the wick to be snuffed without lifting off the chimney.

Lamp-chim'ney Clean'er. (*Domestic.*) A pad or brush for cleaning the chimneys and glasses

Fig. 2793.

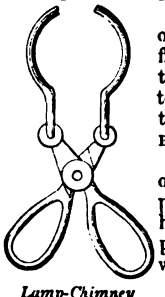


Lamp-Chimney Cleaners.

of lamps. It is usually made expanding, so as to bear upon opposite portions of the inside. A few of the many varieties are shown in Fig. 2793.

Lamp-chim'ney Tongs. An implement for grasping a hot lamp-chimney and removing or replacing it.

Fig 2794.



Lamp-Chimney Tongs.

Lamp-cone. A dome-shaped or conical cap, with a slit for the flame, and placed over and around the wick and wick-tube of a lamp, to concentrate the current of air at throat of the cone. See LAMP-BURNER.

Lamp-el'e-va-tor. A means of adjusting the hight of a suspended lamp in a room. It usually has a telescopic tube, lazy-tongs, or pulleys and chains, with counter-weights. See DROP-LIGHT.

Lamp-hang'er. A means of suspending a lamp, consisting of a ring and chains, or other device.

Lamp-post. A stand for a street-lamp, usually adapted for gas; the pipe rises inside the hollow post, with a burner on top surrounded by a glazed lantern.

Lamp-posts are made to subserve other purposes, such as holding basins for drinking-fountains, the water being conducted up the hollow of the post. Through the same may also pass the wires whereby the jet of gas is lighted by electric action.

Lam'pro-type. (*Photography.*) A polished collodion picture; from the Gr. *lampros*, beautiful.

Lamp-shade. A screen placed above the light to intercept or mellow it. It may have a dark exterior and reflecting interior surface. In the list below are some comparisons of transparent and partially opaque materials.

Loss of Light by Use of Shades and Colored Media.
(*F. H. Storer and Allan Stevenson.*)

Glass, etc.	Thickness. Inches.	Loss. Per cent.
American enameled	$\frac{1}{16}$	51.23
Crown	$\frac{1}{8}$	13.08
Crystal plate	$\frac{1}{8}$	8.61
English plate	$\frac{1}{8}$	6.15
Porcelain transparency	$\frac{1}{16}$	97.68
Parisian pink tinge		57
Deep red		·80
Window-glass	$\frac{1}{16}$	4.27
Window-glass (green)	$\frac{1}{16}$	81.95
Window-glass (ground)	$\frac{1}{16}$	65.75

The shade is usually supported from the lamp-stem or around the base of the burner by means of a three-branched frame known as a *shade-holder*.

Lamp-stove. One in which the heat is obtained by the burning of oil in wicks beneath the kettle, oven, or what not.

Lamp-wick. The capillary or foraminous material which conducts oil or grease to the part where it is consumed in the flame.

Wicks are usually of woven fiber, — cotton, for instance, — but have been made of muslin, paper-pulp, asbestus, biscuit of fire-clay, etc.

The tubular lamp-wick was made for the Argand lamp, to admit air to the inside of the flame as well as the outside. Wicks are also made flat, to admit air to each side of a flat, comparatively thin flame.

The tubular wick for candles, in imitation of the wick of the Argand lamp, has been patented six times in England. Candle-wicks are also made flat; double, with space between, to bend out in burning; wick woven or wound spirally; plaited wire enclosed in longitudinal threads; woven with asbestus; parallel threads laid longitudinally; wicks coated with various materials, such as resin, stearic acid, silicate of soda, size, glue, oil, or in solution of alum, salts of bismuth, borax, chlorate and nitrate of potash, ammonia, sal ammoniac, acetates of lead or zinc; wicks which bend out of the flame in burning; stationary wicks to which candle is raised; double, triple, compound, and multiple wicks; flat wicks, made hollow by folding around a wire; candles with several small wicks.

Lamp-wick Trim'mer. A pair of scissors or nippers specially designed for cutting off the charred tops of wicks without dropping the snuff.

Lan'cas-ter Gun. A cannon with a twisting, slightly oval bore and conoidal projectile.

Lan'cas-ter Ri'fle. One with an elliptic rifling, the bore being slightly oval in section. The twist is one turn in 32 inches, which is the length of the barrel; bore, .498 inch; eccentricity, .01 in half an inch. The lateral expansion of the bullet causes it to fill the bore. Length of bullet, 2½ diameters with a windage of 4 thousandths, and has a paper patch, — the first of its kind. Named from the inventor.

Lance. 1. (*Weapon.*) A weapon consisting of a long shaft with a sharp point, much used, particularly before the invention of fire-arms. It was the principal weapon of the Macedonian phalanx, and the Roman infantry were armed with it as well as with the *pilum* or javelin.

In the Middle Ages it was held in the highest repute by knights and men-at-arms who formed the main strength of European armies; it was gradually superseded by the invention of gunpowder.

The lance used by knights of the Middle Ages was of a peculiar form. Near the lower end the shaft was

Digitized by Google

very thick, with a deep opening in which the arm was placed when the lance was put in rest preparatory to a charge. Immediately in front of the opening, the shaft was from a foot to a foot and a half in diameter, and sloped off towards the upper end, which was from a half-inch to three quarters in diameter.

From this weapon the cavalry of the Middle Ages took their name. A *lance* denoted a man-at-arms (horseman completely armed) with four or five attendants. Among the French in the fifteenth century these attendants consisted of three archers, one *coutilier* (so named from the long broad dirk in his belt), and one page or varlet (mod., *valet*). The introduction of fire-arms gradually led to the disuse of the lance in Western Europe, though it continued in use among the Poles, Russians, and other Sclavonic tribes, as well as the Turks, Tartars, and kindred nations. Frederick the Great introduced lancers into the Prussian army, and was soon followed by the Austrians, who term them *Ulans*, and they have been since introduced into all or most of the armies of Europe.

The lances now in use among the European cavalry have a shaft of ash or beech-wood from 8 to 16 feet long, with a steel point 8 or 10 inches long, and to prevent this from being cut off by a saber stroke, the shaft is guarded by a strip of iron on each side from one and a half to two feet long. The other end has an iron cap to prevent splitting. The point has a small pennon, intended to frighten the enemy's horses. When not in use, the lance is carried in a leathern shoe by the right stirrup, dependent by a leathern thong on the right arm. In use, it is carried under the right arm. Their attempted introduction into the American service in the Army of the Potomac was not a success.

2. (*Pyrotechnics.*) Lances are small paper cases, filled with composition, and attached to light frames of wood or bamboo to mark the outlines of the figures in pyrotechnical devices. Various chemicals are used to give the desired color to the flame, viz.: —

For white: 26 niter, 9 sulphur, 5 mealed powder.

For yellow: 8 nitrate of soda, 2 sulphur, 2 mealed powder, 1 lampblack.

For red: 30 nitrate of strontia, 16 niter, 10 sulphur, 7½ mealed powder.

For blue: 4 niter, 1 sulphur, 2 sulphate of copper, ammoniated.

For green: 12 niter, 8 sulphur, 1 lampblack, 24 nitrate of baryta.

3. (*Carpentry.*) A pointed blade, usually employed to sever the grain on each side of the intended path of a *chipping-bit* or *router*.

It is used in *crozes*, *planes*, and *gages* of certain kinds.

Lance-buck'et. (*Cavalry.*) The shoe in which the butt of a lance is carried by the troopers of certain bodies of cavalry.

Lan'cet. 1. (*Surgical.*) An instrument for bleeding.

a, *gum* lancet with three blades of different shapes.

b, *vaccinating* lancet, spear-shaped.

c, needle-pointed vaccinating lancet.

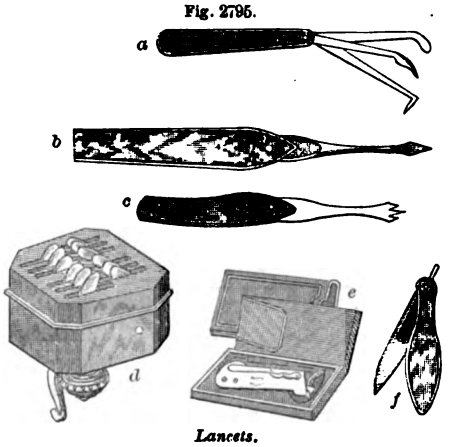
d, *scarificator* for lancing the skin preparatory to cupping.

e, *spring*-lancet for bleeding, consists of a spring, trigger, and blade. The spring is cocked, blade adjusted to the vein, and by pressing the trigger the blade operates instantly. Shown in its pocket-case.

f, *thumb*-lancet, so called from the manner of holding it.

The discovery of minute vessels, termed *lacteals*, which absorb a white liquid, the *chyle*, and pour it into the blood, was made by Aselli, in 1622. Their presence had been noticed by Eristratus in the time of Ptolemy, but their function was not understood. Aselli described them in his *De Venis Lacteis*, Milan, 1627. This work is remarkable as being the first anatomical work illustrated by colored plates. The arteries and veins in red, the lacteals in black.

Fig. 2795.



Lancets.

The smaller circulation of the blood, that from the heart through the lungs and return, was observed by Servetus. He was burnt October 27, 1553, at Geneva, by the order of the city council of Geneva, aided by one who had barely escaped the same fate, and knew better. The pulmonary circulation was distinctly described by Realdus Columbus in his *De Re Anatomica*, published in 1559, and by Andrew Cæsalpinus, who also noticed the refluent motion of the blood in the veins. Sylvius noticed the venal valves. Fabricius, of Acquapendente, noticed that they all opened *towards* the heart.

William Harvey, born in 1578, studied at Cambridge, and under Fabricius at Padua, and made the discovery of the nature of the arterial and venal circulations, and the complete double circulation, in 1616.

Lancets of copper were disinterred in Pompeii in 1819, in the house of a Roman surgeon in the Via Consularis. They were in company with a probe, bullet-hook, catheters, forceps of various kinds, needle, lever for raising depressed bones, cautery, spatulas, etc.

2. (*Metal-working.*) The tapping-bar of a metal furnace.

Lan'cet-arch. (*Masonry.*) An arch with a sharply pointed top. See ARCH.

Lan'cet-win'dow. (*Architecture.*) A high, narrow window terminating in a very pointed arch. It is characteristic of the style of Gothic known as Early English.

Land. 1. (*Milling.*) That part of the face of a millstone which is not furrowed; that which intervenes between the furrows.

2. (*Agriculture.*) The unplowed portion of a field as distinguished from the furrow and the plowed portion.

3. (*Fire-arms.*) That portion of the bore of a rifle which is not occupied by the grooves.

4. (*Steam-engine.*) The unperforated portion of the face-plate of a slide-valve.

5. (*Nautical.*) The lap of the strakes in a clinch-built boat. Also called *landing*.

Lan'dau. (*Vehicle.*) A carriage with a folding

Digitized by Google

top, called from Landau in Germany, where they were originally made.

Lan-dau-let'. A chariot opening at top.

Land'ing. 1. A pier, wharf, or jetty, for disembarking passengers.

2. The platform of a railway station.

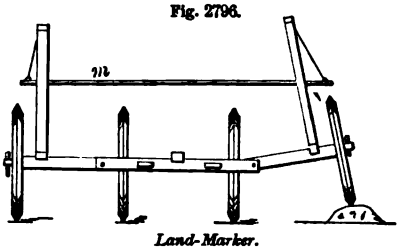
3. The platform of a furnace at the charging hight.

4. A level space at the top of a flight of stairs.

Land'ing-strake. (*Nautical.*) The upper strake but one, of a boat.

Land-mark'er. A machine for laying out rows for planting. In the example, the vehicle has four angular-tired wheels, which are at the required dis-

Fig. 2796.



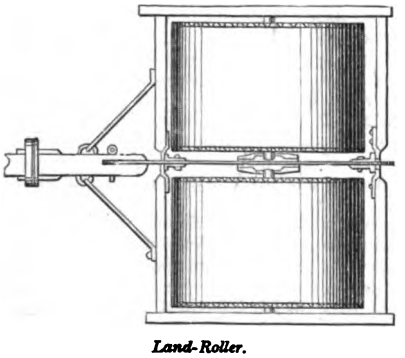
Land-Marker.

tance apart, say 44 to 48 inches, for planting corn, according to latitude and kind of corn. *m* is the driver's seat, supported on posts on the outer sections.

Land-par'ing Ma-chine'. A machine for cutting sods and turfs at a regulated distance beneath the surface. A form of plow.

Land-roll'er. One for leveling ground and mashing clods in getting land into tilth for crops.

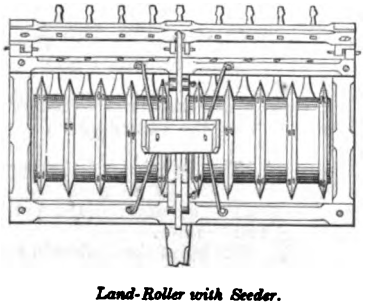
Fig. 2797.



Land-Roller.

In the example, the rollers are so coupled together that they may travel in different planes, and are left free to pass over obstructions independently. The roller in two parts is turned readily, as one may revolve in one direction and the other in the other direction in turning short at the end of a bout.

Fig. 2798.



Land-Roller with Seeder.

Fig. 2798 is a roller with circumferential ridges to break clods, and has a seeding device at the rear.

Land'side. (*Plow.*) The flat side of a plow, towards the land. The lower portion is a bar extending back from the share; and the upper portion is a plate attached to the sheth and the landside handle.

Land-tie. A rod securing a face-wall to a bank. See PILE.

Lan'gate. A linen roller used in dressing wounds.

Lan'grel. (*Weapon.*) A kind of missile formerly used to destroy the rigging of an enemy's vessel.

It was a cylindrical cage or bundle to fit the bore of the gun, and was filled with bolts, nails, and chunks of iron.

Lan-guet'; Lan-guette'. 1. (*Music.*) (Fr. *langue*, tongue.) The tongue of a metallic organ-pipe of the mouth or flute kind. It nearly closes the area of opening in the pipe at a point opposite to the slit, so as to compel the air entering at the lower end of the pipe from the bellows to pass towards the slit which forms the *mouth*. The issuing sheet of air impinges against the metal bounding the upper edge of the slit, so as to divide against the *lip*, and acquire a vibration which is communicated to the column of air in the tube, producing a musical note. See MOUTH-PIPE; PIPE.

2. A thin *tongue* of metal placed between the blades of a comb-cutter's saw, to preserve their distance.

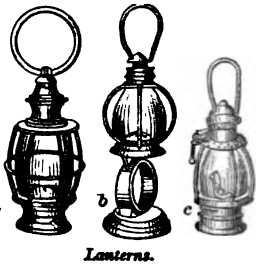
3. A small piece of metal on a sword-hilt which overhangs the scabbard.

Lan'iard. (*Nautical.*) A cord or line for seizing objects on board ship. See LANYARD.

Lan'tern. 1. A case with transparent sides or panes for holding and protecting a luminous body.

The *hand*-lantern (*a*), *arm*-lantern (*b*), *breast*-lantern (*c*), are named from the modes of carrying them.

Fig. 2899.



Lanterns.

They are known on board ship by their position or duty; as, *poop*-lantern, *powder-room* lantern, etc.

Perhaps the original lantern is to be found in some varieties of fireflies, in which the phosphorescent light, like Alfred's lantern (A. D. 890), is protected by a horny covering. The ordinary American firefly and the glow-worm have integuments over their little bunches of brilliancy.

Some species of nocturnal moths sail through the dark oceans of night, carrying lanterns at their prows in the shape of eyes, which, black or brown by day, become glowing sparks in the gloom.

It may not be entirely out of place to class some of these natural lights among the "electric lights." Some of them are intermittent, and we suppose them to be urged into brilliancy by what we call a Voltaic impulse from the battery, the brain.

The *dark*-lantern is arranged to display or hide the light, as may be required. It is used by policemen and by burglars.

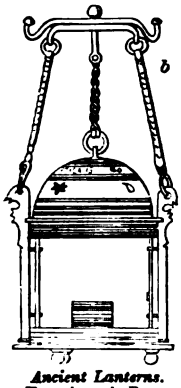
The *magic*-lantern is a mode of displaying pictures, which are made to slide between a light and a lens, their image being thrown upon a screen.

Digitized by Google

Perhaps the earliest example of a lantern is in a sculpture at Alabastron, Egypt (*a*, Fig. 2800), representing a patrol on its rounds, two soldiers being armed with spears, shields, and battle-axes, and a third one carrying a lantern a little in advance. The panes were probably of talc, the lapis specularius of the Romans.

Fig. 2800.

The modern Egyptian lantern consists of a waxed cloth strained over a cylinder of wire rings, and having a top and bottom of perforated copper.



Ancient Lanterns.
a, Egyptian; b, Roman.

The mob came out from Jerusalem to search for the Saviour with lanterns and weapons. The moon rose at about 6 P. M. on that night, but it was probably cloudy, or Judas may have suspected that his master would hide in some covert on the mountain.

Lanterns are referred to by the Greek authors: —

"The man who first invented the idea
Of walking out by night with a lantern,
Was very careful not to burn his fingers."

ALEXIS.

"So taking out the candle from his lantern."

Ibid.

"A well-lit horn lantern."

EUMELUS; quoted by ATHENÆUS, A. D. 220.

The lanterns of Epictetus and Diogenes will not be soon forgotten. See also CANDLE.

Lanterns are referred to by the Roman authors Plautus, Martial, and Pliny; have been disinterred at Herculaneum and Pompeii. In the latter place, one was found in the vestibule of a house alongside a skeleton; the person was evidently trying to escape in the thick darkness of the descending ashes. We read of the use of lanterns in the games of the circus, the sacred games of Greece, in augury, and by the military. In the latter case, the Roman soldier carried the lantern on a pike, as did the Egyptian ten centuries previously, and how much anterior to that time we do not know.

The Roman lantern (*laterna*) was usually of bronze, with panes of bladder, horn, mica, parchment, oiled silk, or sometimes, under the emperors, of glass.

One is shown at *b*, Fig. 2800. It is cylindrical. The bottom plate has three balls for feet, and three posts for suspension. The metal is bronze. Within is a lamp of the same metal. The interior was reached by raising the hemispherical cover.

A great ship-lantern hanging by the poop of a vessel appears on Trajan's column.

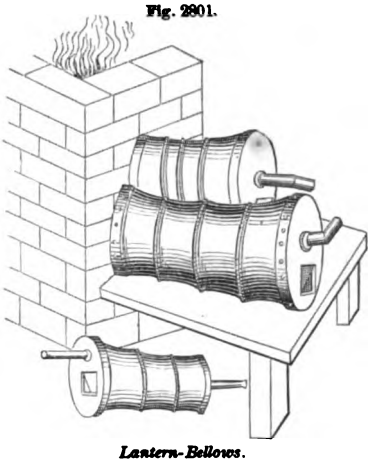
Alfred the Great had a horn lantern around the graduated candle which was his time-measurer.

2. The light-chamber on top of a lamp-post.

3. The upper member of a lighthouse containing the light.

4. (*Architecture.*) A small cupola or dome-topped structure on a roof or tower. A *tholus*. The tholus of the United States Capitol is illuminated by a cluster of burners lighted by electricity from the level of the rotunda floor, 264 feet below.

Fig. 2801.



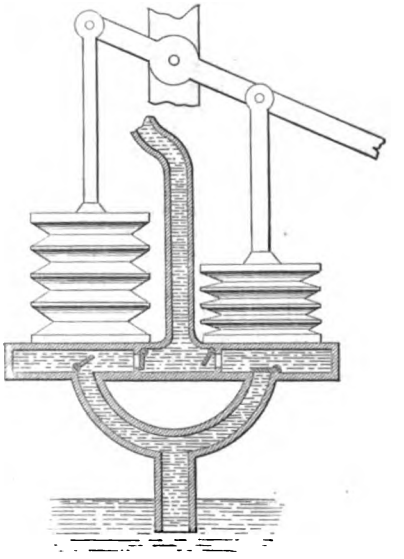
Lantern-Bellows.

5. A trundle-wheel. A *wallower*. See LANTERN-WHEEL.

6. (*Calico-printing.*) A certain description of apparatus by which steam is applied to cloths in order to fix the colors with which they have been printed. The colors consist of a mixture of dye-extracts and mordants. The lantern has a frame with tenter-hooks, from which the cloth is suspended in a zigzag manner; and a penthouse, with a pyramidal roof encloses the frame and cloth, shutting in the steam around them.

7. (*Founding.*) A hollow, perforated core of large diameter relatively to its length.

Fig. 2802



Lantern-Pump.

Digitized by Google

Lan'tern-bel'lows. So called from its resemblance to a paper lantern.

Air is admitted through an inwardly opening valve at the outer end of the bellows in the action of drawing it out, and expelled by pushing it in by means of the handles operated (in the example) by the right and left hands of the workman, their alternate action causing a continuous blast. They may be arranged to be operated by the feet. This apparatus is of great antiquity, and is still in general use in Asia and Egypt.

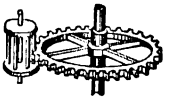
Lan'tern-pinion. A pinion of rundles between disks meshing into the cog-wheel of some kinds of horse-powers. See LANTERN-WHEEL.

Lan'tern-pump. One having a pair of disks at the ends of a flexible cylinder, like a Chinese lantern. See BAG-PUMP.

Lan'tern Stuff'ing-box. A long stuffing-box with tightening bolts, used in some marine-engines.

Lan'tern-wheel. This is allied to the cog-wheel, the bars or spindles which connect the parallel heads being so spaced and proportioned as to engage with the cogs of the spur-wheel. It is a cheap form of wheel, and is seldom used where facilities are at hand for making better. It bears the relation of a pinion to the spur-wheel. It is sometimes called a *wallower* or *trundle* wheel, from the *trundles* or rundles of which it is made.

Fig. 2803.



Lantern-Wheel.

Lan'yard; Lan'iard. (*Nautical.*) A cord, line, gasket, or sennit, for seizing or lashing objects on board ship; as, —

The rope which passes through the *dead-eyes, hearts,* or *thimbles,* used in setting up *shrouds* or *stays.*

The lanyards of the cat-hook; the *fish-tackle.*

The lanyards of the buoy; the *lashing.*

The lanyards of stoppers, etc.

A lashing for securing the gun-ports; fastening spars in their *beckets*; boats to the ring-bolts on deck; the *hatches* to the *coamings;* the binnacle in its place; suspending the hammocks from the hooks of the deck-beams.

(*Ordnance.*) A strong, double-twisted twine about 2 inches in diameter, 12 feet long, and having a hook at one end and a toggle at the other. It is used to pull the trigger of the gun-lock of a piece of ordnance, or to jerk the friction tube, according to the modern plan of firing cannon.

Lap. 1. (*Grinding and Polishing.*) A wheel, disk, or piece of soft metal used to hold a polishing powder, as in cutting and polishing gems. Hence the term "*lapidary's* art." It is usually a rotating wheel on a vertical or horizontal axis, with a working face or periphery respectively.

Laps are made of various metals and alloys, such as *brass, cast-iron, copper, lead,* and *pewter.*

Brass is used by opticians with emery and water, for smoothing lenses and speculums.

Cast-iron is used with sand or emery in many trades; by glass-grinders, opticians, etc. The cast-iron *lap* of the lapidary is called a *skive,* and is charged with diamond-powder.

Copper is used by machinists, by lapidaries, glass-grinders, and glass-engravers. It is usually charged with emery.

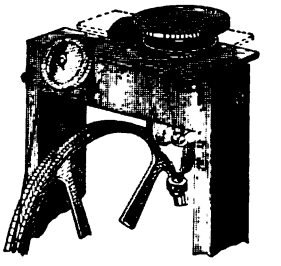
Lead and its alloys are used by machinists, cutlers, lapidaries, jewelers, watchmakers, etc. It is charged with emery, rottenstone, crocus, etc.

Tin, zinc, and their alloys are also used.

The powder in either case is burnished into the metal, the latter merely forming a vehicle for the abradant or polishing-powder.

Lead *laps* sometimes consist of a disk of metal, secured by a screw-nut against a shoulder on the spindle, but are better cast upon a perforated iron plate, which gives rigidity to the *lap,* while the soft lead or pewter allows the grinding-powder to be imbedded therein.

Fig. 2804.



Horizontal Lap.

Some adopt a disk of wood with a leaden tire cast around it.

The cutler's *lap* is cylindrical, and has a wooden center made in several pieces, the grain of the wood presented outwardly, and the disks of which it is composed fastened by circular plates at the ends. The wooden center is turned to the required width, and has a groove in the middle of the face and chamfers at the edges to hold the metallic rim which is cast thereon. This is composed of tin 1, and lead 4 or 5 parts. The edge is then turned true, and is prepared for use by a dressing of emery and oil. Also known as a *glazer.*

This wheel may be used for grinding or polishing, by having regard to the kind of emery, the degree of pressure, and the mode of holding the article. See GRINDING-MATERIALS.

2. (*Steam-engine.*) *a.* Lap of the slide-valve on the steam side is the space which it advances beyond the opening of the steam-port after it has closed it, and is given for the purpose of causing the engine to work expansively, by cutting off the admission of steam before the end of the stroke. *Inside lap.*

b. Lap on the exhausting side of the piston causes the passage to the condenser to be closed before the end of the stroke, the piston being then said to be *cushioned* by the elasticity of the confined vapor upon which it descends. *Outside lap.*

3. A plate covering the line of junction of two iron plates which make a *flush-joint,* and to which they are both connected by solder or lines of rivets. See CARVEL-BUILD.

The usual lap of iron plates in ships is from 5 to 6 diameters at double-riveted joints, and about 3 diameters at single-riveted joints.

4. (*Roofing.*) The distance which the tail of a shingle or slate overlaps the head of the second course below. The overlap on the course immediately below is the *cover.* The exposed portion is the *margin;* the width of the *margin* is the *gage.* The *gage* with shingles is about one third of the length, so that two thirds is *cover.* The *gage* of slates is something under one half the length. The excess over twice the *gage* is the *lap* or *bond.*

5. (*Masonry.*) The overlay of a stone in a wall on its bedstone.

6. (*Fiber.*) A layer or continuous band of cotton fiber made into *batting,* and wound or lapped upon an axis or roller ready for carding.

The sheet of cotton as it enters the carding-machine. As it comes therefrom it is called the *fleece.*

Lap'ar-a-tome. An instrument for performing laparotomy, or cutting into the abdomen in the region of the loins.

Lap-board. (*Tailoring.*) A board resting on the lap and hollowed out on the side next the user. Employed by tailors and seamstresses to cut out work upon.

Digitized by Google

Lap-dove'tail. (*Joinery.*) A form of *secret* or concealed dovetailing, which shows the thickness of the lap only on the return edge, where it has the appearance of a thin board. See DOVETAIL.

Lap-frame. (*Flax-manufacture.*) A machine in which several slivers of carded tow from the *breaker*, or first carding-machine, are united in a lap and wound on a bobbin, from which they may be fed to the *finisher*-card.

Lap'i-da-ry-mill. The grinding and polishing apparatus of the lapidary. See LAPIDARY-WHEEL; LAP.

Lap'i-da-ry-wheel. The art of diamond-cutting was probably known in China and India at an early day, but the stone was little known among the ancients of Europe and Western Asia. Other varieties of stones were mounted and used in great numbers. Pliny refers to gem-cutting: "How many hands are worn down that one little joint of our finger may be ornamented." The Arabians brought the diamond into notice. The discovery of the Brazilian mines in 1730 made it more common. Berghen of Bruges furnished the lapidaries' wheel with diamond-dust, enabling him to cut diamonds, as other stones were cut by the emery previously used. Diamonds were previously set in the rough. They are now cut into *brilliants* or *rose-diamonds*. See BRILLIANT; DIAMOND.

The plano-convex lens of rock-crystal found at Nimroud by Layard showed the marks of the lapidary's wheel. The seals of this wonderful nation required the lap to reduce them to form. They were of various hard materials, such as amethyst, agate, etc., gems and semi-gems. See SEAL.

The wheels of the lapidary are of two kinds.

The *slicer*, which is a thin iron wheel touched with diamond-dust, and used like a circular saw.

The *lap* or horizontal wheel, called a *mill*, whose flat face is touched with materials of a hardness adapted to the subject and to the stage of the work.

The operations are called *cutting*, *grinding*, or *polishing*.

The *mills* are known as *slitting*, *roughing*, *smoothing*, or *polishing*.

The materials of the *mills* are *iron*, *lead*, *tin*, *willow*, *mahogany*, or of wood covered with *list* or *leather*.

The abrading materials are *diamond-dust*, *sapphire*, *ruby*, *corundum*, *emery*, *rottenstone*, etc.

Slicing by a circular saw or *splitting* in the lines of natural cleavage are resorted to when admissible.

The *slitting*-wheel is usually of *iron* touched with *diamond-dust*.

The *grinding*-wheel is usually of *lead* touched with *emery*.

The *polishing*-wheel of tin touched with rottenstone. See DIAMOND-CUTTING.

Fig. 2805 is a view of the lapidary's bench, showing the crank, the driving-wheel, the lap, and the *gim-peg*, which latter has holes in which rest the upper end of the *dopp*, on which the gem is cemented to be applied to the lap. The choice of holes determines the inclination of the *dopp*, and consequently the angle of the facet.

Carnelian, as an example, is first slit with the thin iron slicer, fed with diamond-dust, and moistened with brick oil; secondly, it is rough ground on the lead-mill with coarse emery and water; and, thirdly, it is smoothed either on the same lap rubbed down fine, or with a similar lap used with finer emery.

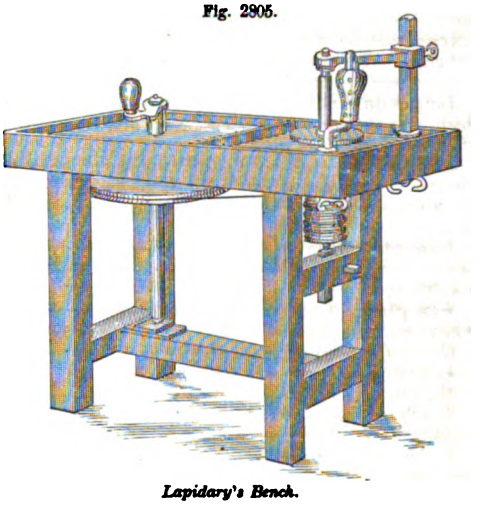
Carnelian, and stones of similar or superior hardness, which are not smaller than about one third of an inch in diameter, are polished on a lead-mill supplied with rottenstone and water. The face of the polishing-lap is *hacked* or *jarred*, to enable the powder to adhere. This *hacking* is done by holding a knife in a slanting position, so as to *chatter* upon the revolving lap and make small furrows therein, which hold the powder.

Smaller and harder stones are polished on a pewter lap, and still harder upon a copper lap.

Rounded stones, said to be cut *en cabochon*, are wrought by means of the *wooden-mill* with fine emery, the *list-mill* with pumice-stone, and *leather-lap* with putty-powder.

Faceted work on pastes and artificial stones, also carnelians, amber, jet, etc., are cut on lead-wheels with emery and polished on pewter with rottenstone. Gems of a somewhat harder kind use a pewter lap and fine emery for the cutting, and a copper lap with rottenstone for the polishing. For sapphires, the

Fig. 2805.



Lapidary's Bench.

chrysoberyl, and some few other stones, a copper lap with diamond-powder is used for cutting the facets, and a copper lap with rottenstone for polishing them. Lastly, for the diamond, two stones are rubbed in a peculiar manner, the one against the other, to start the facets, and they are cut and polished by means of an *iron* lap or *skive* fed with diamond-powder, being cemented on a *dopp* and held upon the *lap* by means of a *gim-peg*, as above described. See also DIAMOND-CUTTING.

Substances treated by the lapidary like carnelian: agate, amethyst, aquamarine, beryl, blood-stone, Brazilian topaz, carbuncle, cat's-eye, chalcedony, chrysolite, chrysoprase, crystal, elvans, emerald, feldspar, flint, fluor-spar, garnet, granite, heliotrope, jade, jaspar, lapis-lazuli, marble, mina nova, onyx, opal, pastes, peridot, plasma, porphyry, quartz, sard, sardonyx, serpentine, topaz. See Feuchtwanger's "Popular Treatise on Gems."

La-pid'e-on. A musical instrument contrived by M. Baudry, made of flints and schist suspended from an iron frame, and struck with a flint hammer to produce the notes. The flints are about forty in number and elongated, but of various lengths and thicknesses. They are arranged in the order of their tone, and the labor and investigation of years were required before the complete scale was formed.

A correspondent of "Nature" writes that in roaming over the hills and rocks in the neighborhood of Kendal, near Lancaster, England, which are

Digitized by Google

composed chiefly of limestone, he had often found what are called "musical stones." They are generally thin, flat, weather-beaten stones, of different sizes and peculiar shapes, which, when struck with a piece of iron or another stone, produce a musical tone instead of the dull, heavy, leaden sound of an ordinary stone. The sound of these stones is in general very much alike, but sets of eight stones have been collected which produce when struck a distinct octave. The new French scientific weekly, "La Nature," copies the communication from its English namesake, and brings forward some additional instances of the same phenomenon. It tells of a performer who played musical airs on rough flints suspended by silk threads, striking them with an iron rod. We are also informed of the accidental discovery of musical properties in a stone fountain at the French Institute. A distinguished musician, A. Elwart, having struck it with the palm of his hand, elicited "a musical sound corresponding with extreme precision to the perfect accord major of *fa* natural." The fountain in question is in the grand court of the Institute.

La'pis-laz'u-li. A rare ornamental stone of a deep blue spotted with a deeper blue, and intermixed with a few grains of gold.

Lap-joint. One layer overlapping the edge of another; as the *clincher*-build of boats. Illustrations are also found in *halving*, *scarfing*, and *cauking* of timbers (which see).

Lap-ma-chine'. (*Spinning.*) A *spreader*, *spreading-machine*, *blower and spreader*. See LAPPING-MACHINE.

Lap'ping. 1. Grinding or polishing on wheels whose metallic rims are provided with emery and oil.

Glazing is done on wooden wheels.

Polishing on leather-covered wheels.

Buffing on leather, with rouge.

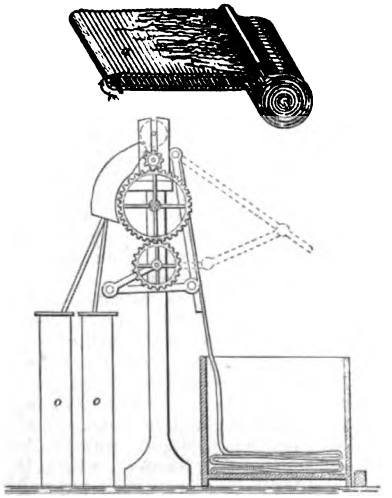
2. (*Spinning.*) Laying several fleeces or slivers together. See LAPPING-MACHINE.

3. (*Fabric.*) A machine blanket used by calico-printers.

4. (*Ordnance.*) Wearing away the land surface in a rifled gun to ease the entrance of the projectile.

Lap'ping-ma-chine'. (*Cotton Manufacture.*) *a.* A machine in which cotton is reduced to a downy condition, spread equally, subjected to a certain compacting pressure, and then wound in an even continuous wad (*wadding*) upon a roller, forming a *lap*.

Fig. 2806.



Lapping-Machines.

Prepared cotton may be spread upon the traveling apron *a*, in weighed quantities, covering a marked area, as between occasional black slats; or it may be formed into a *lap*, after a succession of scutching and blowing operations. See BATTING-MACHINE.

b. After cotton has undergone a preliminary carding in the *breaker*, from which it comes in the form of a thin fleece, several of these fleeces are joined to form one thickness.

In another form of *lapping-machine*, several cans *o o*, filled with a narrow fleece from the breaker-card, are placed in two rows, and the ends of the fleeces brought together between two rollers, the lower one driven by a wheel and pinion and the upper one pressed down upon the former by weights.

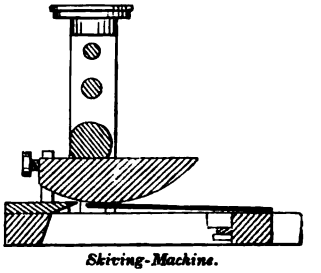
Lap-ring. An open ring in which the ends lap past each other without touching, so that it may form a connecting link for attaching the single-tree to the *clip* of the *double-tree*, or connecting the ends of a broken chain, etc. A *cotter* is a better device for the latter purpose, however. (See COTTER.) The *lap-ring* is somewhat like a *split-ring*, but the latter is elastic. The heavy material of the *lap-ring* precludes elasticity.

Lap-roll'er. (*Fiber.*) One in a lapping-machine, upon which the fleece or wadding is wound.

Lap-shav'er. A machine for shaving leather to a thickness by means of a knife set to a graduated distance from a roller or an edge over which the hide or piece of leather is passed. The term is derived from the old practice of shaving away inequalities by means of a knife while the leather laid upon a board in the lap.

Lap Skiv'ing-ma-chine'. A machine for scarfing off the thickness of leather towards the edge. In Fig. 2807, as the strap is drawn across the edge of the knife, the eccentric gage-block swings on its bearing and gradually descends, tapering the strap toward the end. Each part is adjustable to vary the operation within given limits.

Fig. 2807.



Skiving-Machine.

Lap-stone. A stone laid in the lap, and used as an anvil by a shoemaker in hammering his leather.

Lap-streak. A structure, usually in boats, in which each streak or plank *laps* over the one below it. *Clincher-built.*

Lap-weld. (*Forging.*) A weld in which the welding edges are thinned down, lapped, and welded.

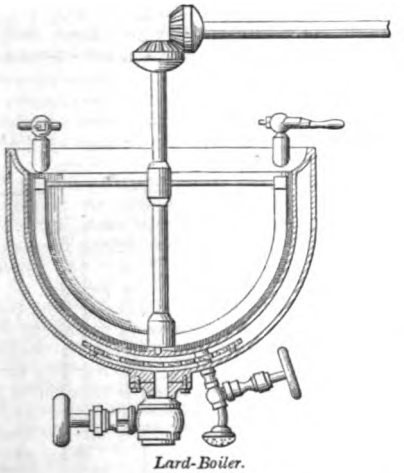
Lar'board. (*Nautical.*) The left side of a vessel to a person standing on deck and facing toward the bow. From the Italian *quella borda*, that side; in contradistinction to *questa borda*, this side; abbreviated into *la borda* and *sta borda*. *Port* is now substituted for larboard, to give a greater difference in the sound of the word of command.

Lard-boil'er. A steam-heated pan in which the fat of hogs is boiled, to obtain the lard by the shrinkage and hardening of the membranes. In the example, the hemispherical boiler has double walls, with openings for the inlet of steam, the discharge of air

Digitized by Google

and condensed water, and an exit opening, with a strainer for the lard. Stirrers revolve within the

Fig. 2808.

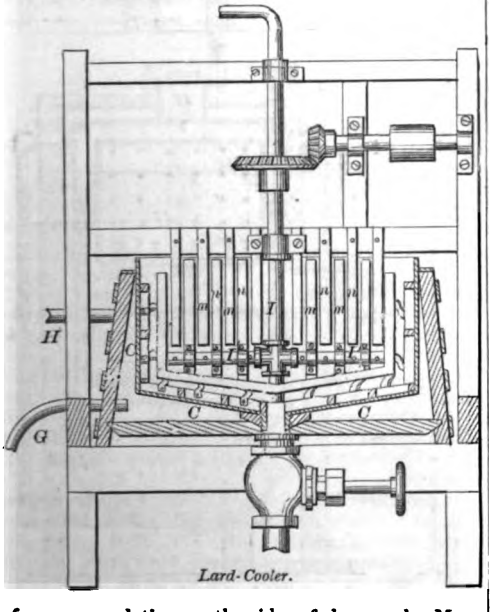


Lard-Boiler.

pan, and a perforated plate above the steam inlet distributes the steam upon the bottom of the pan. See also LARD-RENDERER; LARD-TANK.

Lard-cool'er. One in which rendered lard is artificially cooled. The inner vessel containing the lard is surrounded by a space *C* to be filled with cold water, passed in and out through pipes *H G*. Air is forced through a tubular shaft *I* into the inner vessel. Wooden scrapers prevent the cooled lard

Fig. 2809.

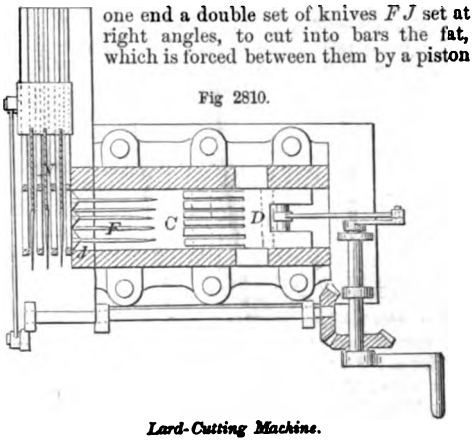


Lard-Cooler.

from accumulating on the sides of the vessel. Movable wooden slats *m* pass between fixed ones *n* to agitate the liquid contents of the inner vessel.

Lard-cut'ter. One for cutting lard for rendering. This is usually performed by knives at a bench; but, in the example, a close trough *C* has at one end a double set of knives *F J* set at right angles, to cut into bars the fat, which is forced between them by a piston

Fig 2810.

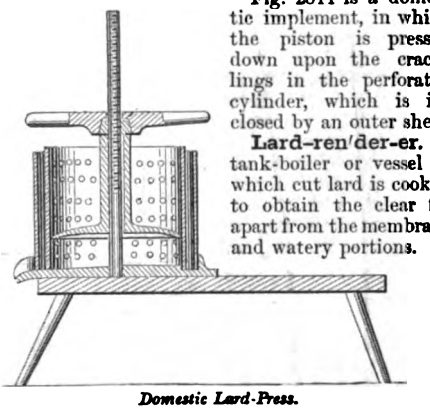


Lard-Cutting Machine.

D. The bars are then cut into short pieces by knives *N* reciprocated transversely to the trough.

Lard-press. A press in which cooked lard is pressed from the cracklings.

Fig 2811.



Domestic Lard-Press.

Fig. 2811 is a domestic implement, in which the piston is pressed down upon the cracklings in the perforated cylinder, which is inclosed by an outer shell.

Lard-ren'der-er. A tank-boiler or vessel in which cut lard is cooked to obtain the clear fat apart from the membrane and watery portions.

Lard-tank. A vat in which fats are cooked to obtain them free from watery matters and membrane.

Wilson's tank is a vertical cylinder with a charging hole at top; a steam-jacket and steam-coil for heating; try-cocks at different hights for examination of contents; discharge-cocks at different hights for drawing off the liquid oil and the water; discharge-hole, with cover at the bottom, to remove the solid matter from the bones and fibrine.

In Everett's apparatus (Fig. 2812) the digester, containing the fat, is surrounded by an outer shell constituting a hot-water and steam space, to which it is connected by stay-rods, which unite the water-space at bottom with the steam-space at top, and pass through the vertical flues *A B*. The vapors from the digester, charged with odors and organic matter, pass through a pipe at top of the apparatus into a super-heating coil over a furnace, into which they are finally discharged and consumed. A spiral flue surrounds the outer case of the boiler.

Broadnax's apparatus consists of an exterior casing of masonry in which the digester, which may be of the form shown either in the upper or lower figure, is placed. In the first it is stationary, and consists of an inner and outer shell, between which

Digitized by Google

and through flues in the inner one *A A* the heat circulates. The rendered fat, in a fluid condition, descends from shelf to shelf, and is strained through the perforated bottom *C*, whence it is drawn off. The furnace has an inclined flue at each side, through which the products of combustion pass to and around the digester. Gases from the digester are delivered into the furnace. This may be effected, as shown in the first figure, by an air-pump *J* and condenser *K*, by which the gases withdrawn from the digester are compelled to pass through a cylinder, heated by a grate *P*, in which the watery particles are condensed by a series of plates *i j* and drawn off by a pipe; the dry vapor, ascending, passes through another pipe to assist in heating the furnace.

In the lower figure, the perforated digester *G* is mounted on trunnions and rotated by a crank; the oil exuding is strained through the diaphragm *E*, and the gases pass through the pipe *I* to the furnace. *H* is the charging manhole.

Large-face Lathe. (*Wood-working.*) A lathe for turning patterns of wheels, heavy moldings, and other large circular work. It has a hinged tool-rest on a bracket, which may be moved out of the way to allow the work to swing to the floor if necessary; or even larger work may be done by preparing a pit for the object to swing in.

Lar'get. A piece of bar-iron, cut off to a length (and weighing say about 14 pounds for an average sheet), forming a blank to be heated and rolled into a sheet of iron. (English Spec. 14,244.) It is to the *sheet* what the *loop* is to the *bloom*, the *fagot* or *ball* to the *bar*.

Lar'i-at. A rope 1¼ inches in circumference and 30 feet long, used for picketing horses in camp. It is fastened to a ring on the picket-pin, which is driven into the ground, permitting the horse a limited circle to graze in.

Fig. 2813.

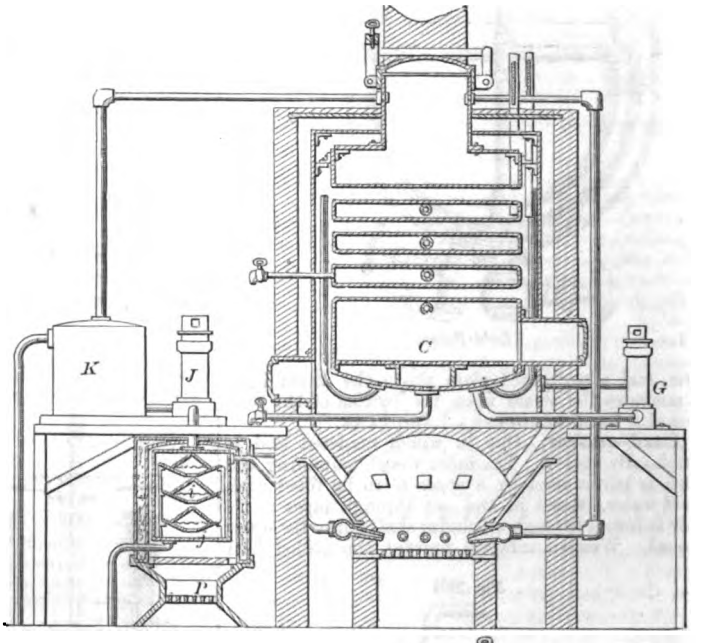


Fig. 2812.

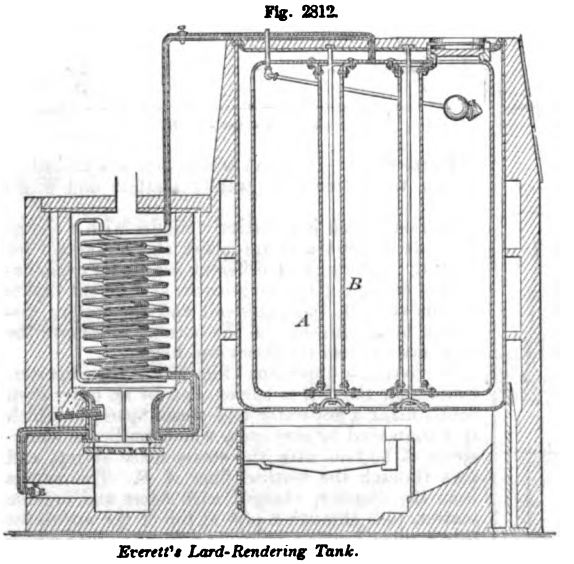
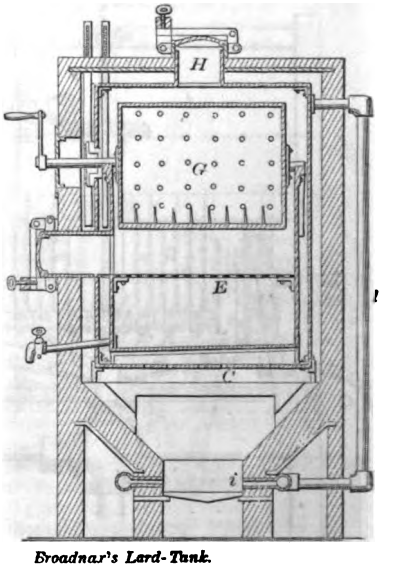


Everett's Lard-Rendering Tank.



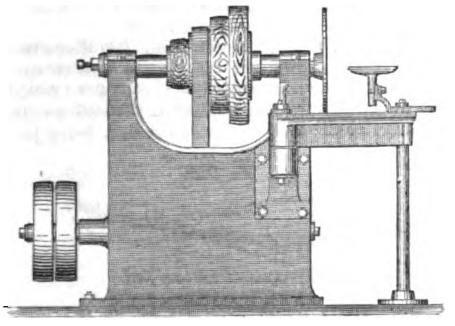
Broadnax's Lard-Tank.

Lar'mi-er. (*Architecture.*) The corona or dripstone of a doorway or window-way.

Lar'yn-ge'al E-cra'seur. (*Surgical.*) An instrument for extirpating abnormal growths of the larynx and epiglottis. It consists of a steel rod,

Digitized by Google

Fig. 2814.



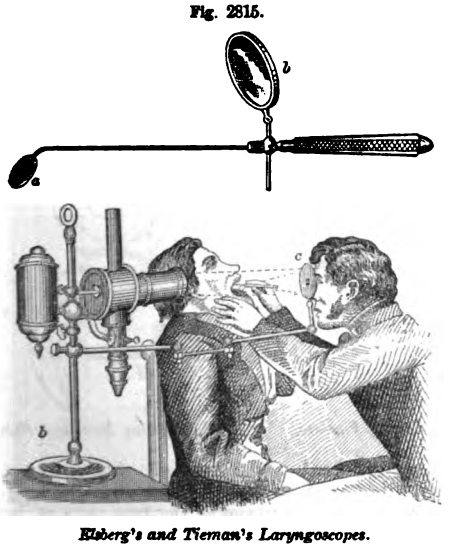
Large-Face Lathe.

about 8 inches long, curved, and fenestrated at one extremity. A wire loop is first passed around the object to be extirpated, is drawn through the fenestrum *slowly*, by means of either a screw or lever at the other end of the instrument, thus *crushing* it off.

By this method (ecrasion) the loss of blood is avoided.

La-ryn'go-scope. An instrument for obtaining a view of the larynx. It consists of a small plane mirror *a* on a long, slender stem, which is introduced to the back of the throat, and a *large* concave mirror *b* for reflecting light (solar or artificial). This last reflector may be either fixed to a stand or suspended from the forehead of the operator. An *inverted* image is seen in the *small* mirror. The upper figure is Elsberg's laryngoscope. When artificial light is employed, the patient should sit so that it is a little back of him and on his right side, as in Tieman's instrument (the lower figure). In this case, the light is reflected by a concave mirror *c* to

Fig. 2815.



Elsberg's and Tieman's Laryngoscopes.

the smaller mirror, which is held by the observer at the posterior part of the mouth, the uvula resting upon its back. By its means, the vocal chords of the interior of the larynx are exhibited, and have been photographed. One constructed by Dr. Turck in 1857 was modified and improved by Dr. Czermack of Pesth, 1856, who exhibited it in action in 1862, in London. Mr. John Avery of London is said to have constructed a similar apparatus in 1846.

La-ryn'go-tome. Laryngotomy, or the opening of the larynx, was practiced by the ancients in quinsey. It was recommended by the Greek and Arabian physicians, by Galen and Asclepiades decidedly.

Lash. 1. (*Weaving.*) A thong formed of the combined ends of the cords by which a certain set of yarns are raised in the process of weaving Brussels carpet. Each yarn (termed an *end*) passes through an eye (the *mail*), to which is attached a cord passing over a pulley above the frame of the loom. The cords required to raise to the surface a certain set of yarns, required for one row in the pattern, are bound together into a lash, so as to be operated by a single pull. See BRUSSELS CARPET.

2. The thong or braided cord of a whip.

Lash'er. (*Nautical.*) The rope which binds a gun to the rings at the cheek of the port.

Lash'ing. (*Nautical.*) A rope or gasket, by which anything is secured on board ship, by wrapping around it.

Fig. 2816.

Lashing.

As the *lashing* of a studding-sail boom.

The lashing of the parts of a pontoon-bridge.

The lashing at the head of a *shears*.

The lashing of a tail-block.

Also the act of binding one thing to another.

Las'ket. (*Nautical.*) One of the rings of cord on the head of a *bonnet* or *drabbler* to secure it to the foot of the sail above, by a lacing cord. A *latch*.

Lasque. (*Diamond-cutting.*) A kind of table diamond. See "Jeffries on the Diamond."

Las'so. A rope with a running noose, used in Spanish America and Texas for catching cattle, etc.

In the British cavalry, 10 men per troop are furnished with a *lasso*, not as a weapon, but that they may aid in drawing a load on emergencies.

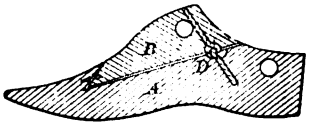
The lasso was used in war by the ancient Egyptians, as we see by the paintings at Thebes.

The Sagartians, a cavalry contingent of the army of Xerxes, used "lassoes which end in a noose." — HERODOTUS, VII. 85.

The lasso is seen in the sculptures upon the palace of Asshur-bani-pal, a son of Esarhaddon, which are now in the British Museum. Pausanias states that the Sarmatians used it; Suidas, that it was used by the Parthians. To this list may be added the Huns, the Alani, and among moderns the Pampas Indians of South America.

Last. A foot-shaped block *A B* placed inside a shoe, to give shape to the upper and hold the parts, which are tacked thereto previous to pegging.

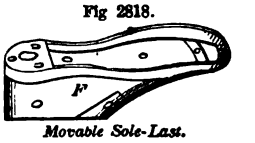
Fig 2817.



Shoe-Last.

F is a last, shown side up, to expose the sole, which has a metallic rim around the edge to hold a wooden sole, which may be replaced when worn out.

Fig 2818.



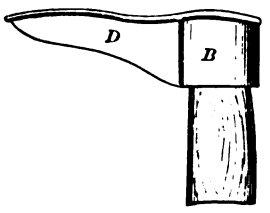
Movable Sole-Last.

D B is a metallic foot-shaped anvil for holding boots and shoes while clinching nails.

Lasts are mentioned by

Digitized by Google

Fig. 2819.



Last-shaped Anvil.

the Greek authors. Right and left lasts were introduced in England about 1785.

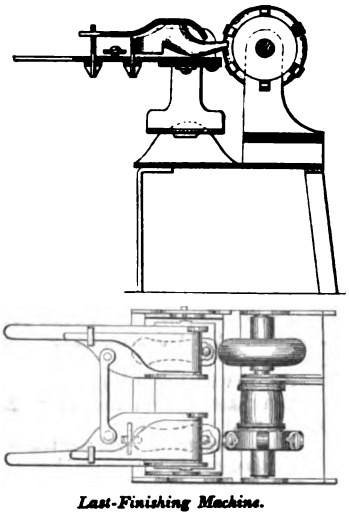
Last'age. (*Nautical.*) Ballast or lading in a ship.

Last'er. A tool for stretching the upper leather over a last. See LASTING-TOOL.

Last-fin'ish-ing Ma-chine'. A machine in which the ends of lasts, which are held in the chucks of a last-turning machine, are dressed up and finished.

Fig. 2820 shows a lathe having a revolving cutter

Fig. 2820.

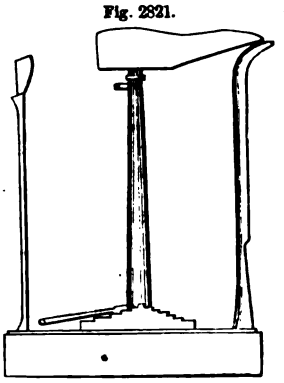


Last-Finishing Machine.

to operate upon the last at the same time and in the same direction that the guide-wheel presses upon the pattern. The supporting frame is on the pantograph principle, and any change in the position or form of the model is reproduced in the last.

Last-hold'er. (*Shoemaking.*) A standard for the last while lasting, pegging, sewing, soleing, etc.

Fig. 2821.



Last-Holder.

The last is placed upon a standard rotated by a lever, to bring the toe of the boot against the rest-standard at either end of the base. One standard gives an upward support for pegging, and the other a side support for sewing. The lever is held by a ratchet.

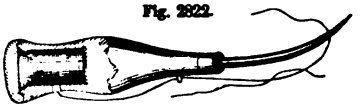
Last'ing. 1. (*Fabric.*) *a.* A five-leaf twill stuff; a stiff woolen fabric in which horsehair was formerly interwoven to form a stiffening for stocks or dresses.

b. A woolen fabric used in making women's shoes.

2. (*Shoemaking.*) The process of drawing the upper leather smoothly over the last.

Last'ing-awl. A sewing awl for shoe-closers. The example shows one carrying a bobbin in the handle of the awl, leading the thread out through a hole in the handle, and passing it through an eye in the point of the awl. In use, the awl, being passed

Fig. 2822.



Eye-Pointed Lasting-Awl.

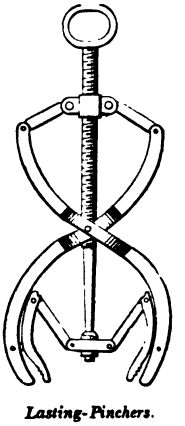
through the leather, carries with it the thread; then being slightly drawn back, it forms a loop through which a second thread is passed. The entire withdrawal of the awl then makes a lock-stitch, similar to that made on some sewing-machines.

Last'ing-jack. An implement to hold the last while straining and securing the upper thereon; and for centering or adjusting the insole and outsole for the subsequent action of the pegging or sewing-machine. Sometimes used in hand-pegging.

Last'ing-ma-chine'. (*Shoemaking.*) A device for drawing the upper leather of a boot or shoe smoothly over the last, turning the projecting edges down upon the insole, and holding them until they are properly secured by tacks or other fastenings.

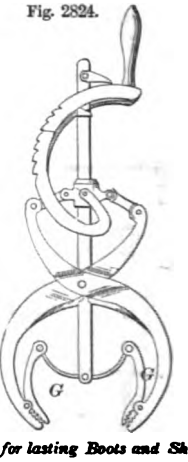
Last'ing-pinch'ers. (*Shoemaking.*) A tool to grip the edges of the upper leather of a boot and draw it over the last. The two jaws are gripped simultaneously upon the edges of the leather, by the motion of the nut *C* upon the screw, and the same movement brings the jaws toward each other and stretches the leather around the last.

Fig. 2823.



Lasting-Pinchers.

Fig. 2824.



Tool for lasting Boots and Shoes.

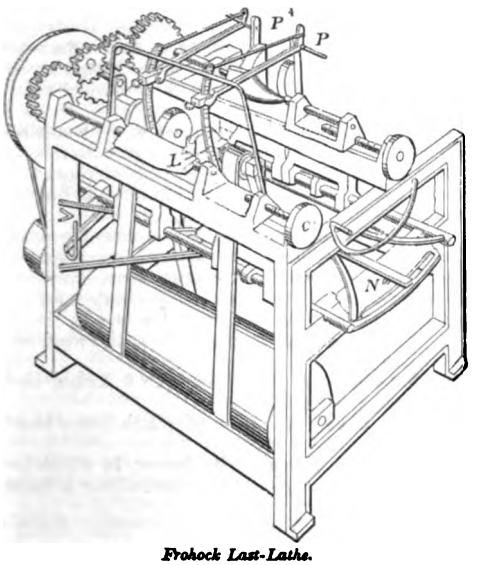
Last'ing-tool. (*Shoemaking.*) A tool for gripping the edges of an upper leather and straining it over a last. In the example, the two pairs of jaws *G G* engage the sides of the leather, being drawn thereupon and inward simultaneously, by the action of the cam lever.

Last-mak'ing Ma-chine'. (*Wood-working.*) A machine for cutting lasts from the block or blank. The work is usually done in a LATHE FOR TURNING IRREGULAR FORMS (which see).

Such is also the machine (Fig. 2825) in which, by a train of gearing, the block L^5, from which the last

Digitized by Google

Fig. 2825.



Frohock Last-Lathe.

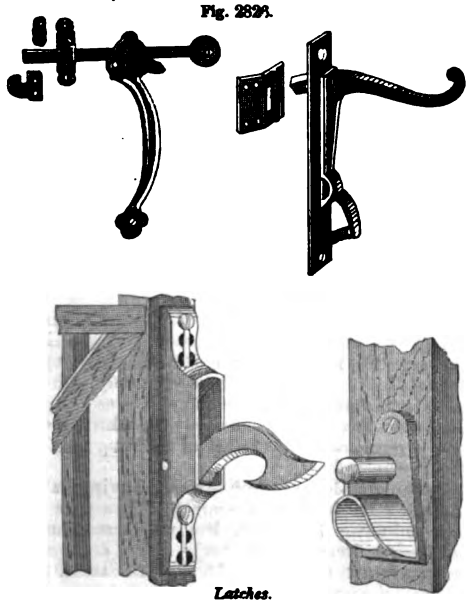
is to be cut, is made to present a face to the cutters precisely corresponding to the face of the model against guides on rods *P P'*. By moving links on these rods up or down on their graduated scales, the last may be enlarged or reduced in its relative proportions to the model. A similar variation of the bar N'' on the sector at the end of the machine will vary the work in relation to its length as compared with the model.

Last-turn'ing Ma-chine'. See LATHE FOR TURNING IRREGULAR FORMS.

Latch. 1. (*Hardware.*) A door-fastening, consisting of hinge-bolt and catch. A latch may be opened from either side of the door or gate.

Latches are known by purpose, or peculiarity of construction, as —

Fig. 2826.



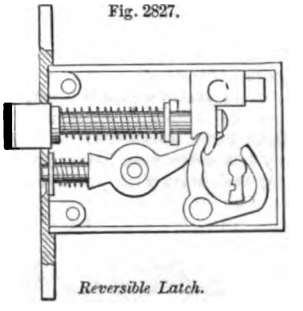
Latches.

Rim, night, sliding-door, gate, thumb latches.

The upper examples in Fig. 2826 are a *thumb*-latch and *gate*-latch respectively. The lower is a *gravitating* gate-latch, the catch and its keeper being shown detached.

A reversible latch is one in which the bevel of the bolt can be set in either direction, so as to make the latch answer for a right or a left hand door. The bolt is simply pulled out, turned half round, and then released, the spring bringing it back to place.

Fig. 2827.



Reversible Latch.

2. (*Knitting-machine.*) The piece hinged to the needle, which closes over the engaged loop to hold it in position in the needle while the latter is penetrating another loop. The latch is subsequently opened by the latch-lifter to allow the loop to be pushed back upon the needle, and is then closed by the latch-closer to enable the *knock-off* to disengage the formed loop or stitch. The *latch* is sometimes called the *fly*.

3. (*Nautical.*) *a.* A cord clamp which holds the in-board end of a mackerel-line. A *mackerel-latch.*

b. A loop on the head-rope of a bonnet-sail. A *lasket.*

Latch-clos'er. (*Knitting-machine.*) The piece which closes the latches, to enable the *knock-off* to slip the formed loops off the needles.

Latch-key. A private key for a street-door latch.

Latch'ing; Las'ket; Latch. (*Nautical.*) A loop formed on the head rope of a *bonnet-sail*, by which it is connected to the foot of the sail to which it forms an appendage.

Latch-lift'er. (*Knitting-machine.*) The rod or finger which lifts and reverses the latches to enable the loops or stitches to be pushed back along the needles.

La-teen'-sail. (*Nautical.*) A triangular sail, having its upper edge fastened to a long yard which is inclined at an angle of about 45°. The yard is slung at a point three quarters of its length from the peak end. It is used principally in the Mediterranean, upon *xebecs*, *galleys*, and *feluccas*, which have three, two, and one mast, respectively.

Lateen-sails of papyrus were used by the ancient Egyptians on the Nile.

La-teen'-yard. (*Nautical.*) One used in extending a *lateen*-sail. It is slung at a point one quarter of the length from the tack of the yard.

Lat'er. A brick or tile.

Lath. 1. (*Carpentry.*) One of the strips of wood nailed to the rafters to support the roof-covering.

2. (*Plastering.*) One of the narrow strips nailed to the studs of partitions to support plastering.

Strips of metal are sometimes used for this purpose in fire-proof structures. Such lath have means for securing to the studding or wall, and also affording a *key* to the mortar which is laid thereon.

Slips of wood, used in plastering, are noticed by Pliny.

Lath floated and set fair. Three-coated plasterers' work. The first is called "*pricking-up*"; the second, "*floated*"; the third, "*finishing.*"

Lath laid and set. Two-coated plasterers' work.

Digitized by Google

The first is called *laying;* the second, *finishing.*

Metallic lath for wooden or iron partitions has been made in various forms, of which the annexed instances may be given : —

a has a corrugated plate and transverse rods, behind which latter the plaster makes its lock.

b has plates with dovetail holes in which the plaster fastens.

c has corrugated plates which catch upon hooks on the studding.

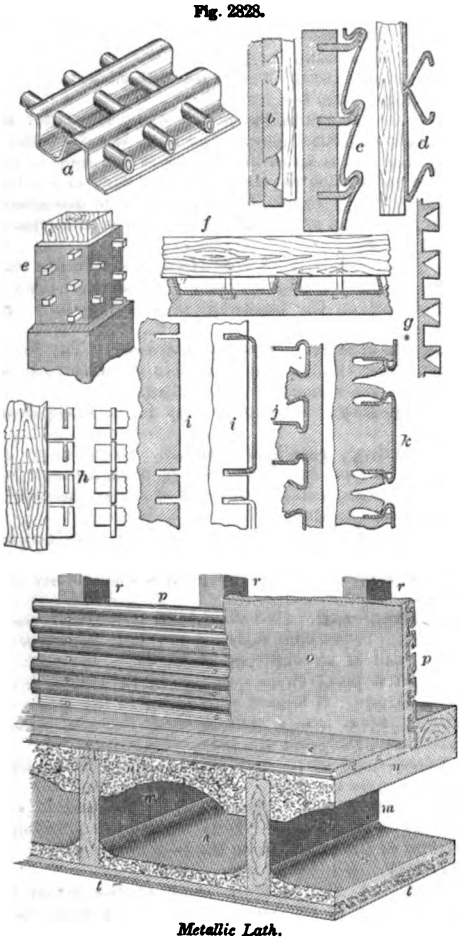
d has plates which present bent prongs.

e has metallic plates with frustums presenting their bases outwardly.

f has strips with flanged corrugated edges.

g has sheets with projecting studs of frustal form.

Fig. 2828.



Metallic Lath.

h has iron slats which are held by slotted iron plates driven into the studding.

i i show a form in which the edges of bent slips enter slots in the studding.

j has bent strips which occupy depressions in the studding.

k has means for pinching the edges of the lath.

The lower figure represents a portion of a structure in which the wooden joists and studding are so isolated from each other and protected externally that the wood cannot be readily fired by exposure to flame.

m m are the wooden joists ; *n n* protecting bodies of concrete ; *t* the corrugated lath whose trough-like shape enables it to form a key for the plaster, to protect the joist from the effects of fire in the room below, the portion of the plaster in the trough acting as a clinch for the outer portion of the plaster which forms the ceiling surface.

The same may be said in regard to the wall plastering *o*, which is spread upon similar metallic lathing *p* on the studding *r*. The upper body of concrete *n* extends above the joists, so as to isolate the flooring *s* therefrom.

This plan is a compromise, and retains the usual wooden portions of a floor or partition, excepting the wooden lath, for which corrugated sheet-iron laths are substituted. The laths are perforated for attachment by nails in the usual manner.

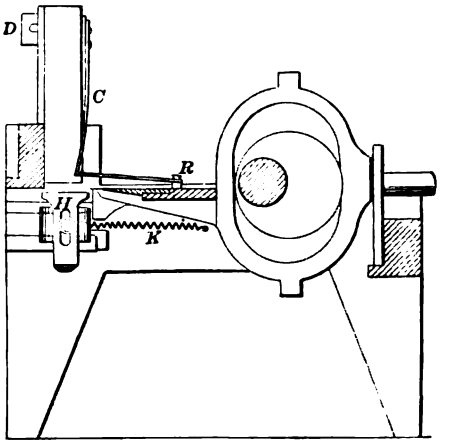
3. A bedstead slat for supporting the mattress. See BED-BOTTOM.

Lath-brick. A long brick, 22 × 6 inches, used for oast or grain-kiln floors.

Lath-cut'ter. One for cutting lath from a board or balk.

The example is one of the former, in which the lath is cut by a reciprocating knife from a board

Fig. 2829.



Lath-Cutter.

which is fed thereto by its gravity. A flexible adjustable guide *C* preserves the perpendicularity of the board and releases it after the cut. The rests *H* reciprocate in dovetail slides and are operated by the bumper on the knife-frame *R* and the recoil spring *K*. The knife is reciprocated by a cam and yoke.

Lathe. 1. A machine in which the object revolves while it is shaped by a cutting-tool applied to it.

Turning, as an art, is believed to have originated with the potter's-wheel, which consisted of a simple disk or table rotating in a horizontal plane, upon a vertical shaft. This wheel was used only with plastic material formed by the hand, and is as ancient as the oldest Egyptian monuments, in which the god Ptah is represented in the act of molding man upon the throwing wheel.

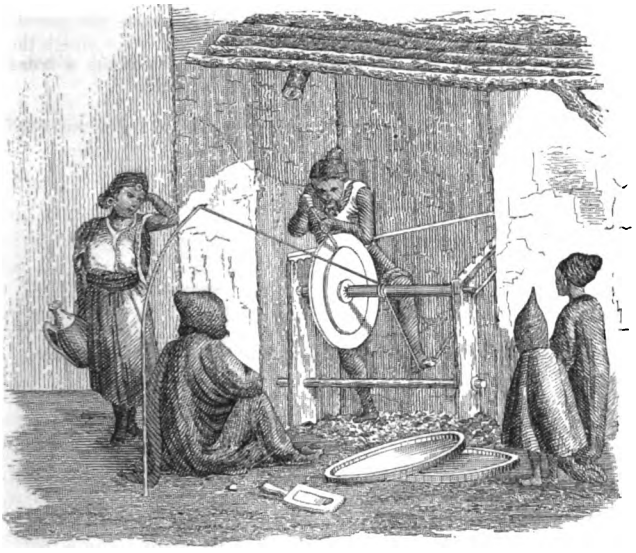
The turning-lathe proper (*tornos*), having its work suspended on horizontal centers, appears to have been unknown in Egypt, but was mentioned by the Greek writers some centuries before our era, and was employed on wood. Its use for metal is of comparatively recent origin.

Digitized by Google

The credit of the invention is given by Diodorus Siculus to Talus, the grandson of Dædalus, about 1240 B. C., and by Pliny to Theodorus of Samos. The initial mode is probably the *pole-lathe*, in which the stick of wood is suspended on two centers and rotated by power applied directly to it, while a cutting-tool is supported on a rest and brought into contact with the rotating wood. An advanced form would be to apply the power to a mandrel whose end formed one of the centers and upon which the wood was chucked.

Fig. 2830 shows the foot-lathe of the Kabyles, an African people. The turner is shown making a wooden bowl. The motion is reciprocating; as the man presses with his foot in the bight of the cord the bowl is rotated towards him, and he applies the chisel or other cutting-tool. He then lifts his foot, and the elasticity of the spring-bar, which has been bent over, rotates the bowl in the other direction and

Fig. 2830.



Pole-Lathe (Africa).

lifts the bight of the rope, ready for another effective stroke.

The lathe of the native East-Indian consists of two upright pieces of wood driven into the ground at the requisite distance for holding the work, with spikes projecting horizontally. The work is held between these spikes and made to rotate backward and forward by a bow held in the left hand, and the string of which is passed once round the wood. Fig. 2831 shows a pole and treadle lathe used by people of the Carpathian Mountains. The work *a* is suspended on centers *b b*, and rotated by the cord which connects the end of the spring-pole with the treadle *c*. The chisel rests upon the bar.

Fig. 2831.

Lathe of the Carpathians.

The earliest screw-lathe known is one described in the work of Jaques Besson (see Plate 9 of that work) published at Lyons, France, in the year 1578. This curious lathe, which is also illustrated and described on page 616, Vol. II., Holtzapffel's "Turning and Mechanical Manipulation," has its tool traversed alongside the work by means of a guide-screw, which is moved simultaneously with the work to be operated upon, by an arrangement of pulleys and cords clearly shown in the engraving. Besson's machine was capable of cutting screws of any pitch by the use of pulleys of different diameters, and could be made to cut right-hand or left-hand screws at pleasure, by crossing or uncrossing the cord. The inventor also describes its application to elliptical, conical, or other solids.

A metal-turning lathe, in its most essential details, is found described on page 214 of "Mechanick Exercises, or the Doctrine of Handy Works," by Joseph Moxon, hydrographer to King Charles II., printed in London, 1694. This is cited, however, rather as one of the earliest intelligible and illustrated descriptions which have come down to us, than as fixing the actual date, — for evidence exists of its much earlier origin; for example, a bronze drinking-vessel, five inches in diameter, and *evidently turned*, was exhumed from an ancient tomb in Thebes, Egypt. This vessel may be seen in the Abbott collection, museum of the Historical Society at the corner of Second Avenue and Eighth Street, New York.

In the earlier construction of the lathe, the *slide-rest* was the first great step toward the principle of the *slide-lathe*, and no doubt led to that invention, which was considered impracticable before planing-machines were made of sufficient magnitude to plane a lathe-bed of even small dimension. A few slide-lathes had indeed been made, the beds of which were composed of a timber framing, covered with iron plates on the upper side to preserve the surface, similar to those which were previously used for the ordinary hand-lathes, with the exception that the outer edges of the iron plates were made of suitable shape to form the Vs for the carriage to slide upon. It was not, however, until some time after the introduction of the planing-machine that slide-lathes came into general use, and their utility was fully acknowledged.

The application of a *screw* to the *slide-lathe*, so as to render it capable of both *sliding* and *screw-cutting*, was the next important improvement; and a great amount of time, perseverance, and capital was expended by a few persons in endeavoring to perfect this portion of the lathe. A short screw was first made, as accurately as possible with the rude means then possessed, from which one was cut double the length, by changing the turned bar end for end in the lathe after cutting one half. Subsequently, by following out this principle, screws were made of any length required.

After this, the *surfacing motion* was introduced, and also the use of a shaft at the back of the lathe, in addition to the regular screw, for driving the slid-

Digitized by Google

ing motion by rack and pinion, instead of both the motions of sliding and screw-cutting being worked by the screw alone; for it was found that the threads of that portion of the screw nearest the fast head-stock, being most in use, were worn thinner than the other parts; and, in consequence, the lathe did not cut a long screw with the degree of accuracy which it otherwise would have done.

Thus, step by step, improvements were gradually brought forward; the fore-jaw and universal chucks and other important appliances were added, so as to render the lathe applicable to a great variety of work, even cutting spiral grooves in shafts, scrolls in a face-plate, skew-wheels, and also turning articles of oval, spherical, or other forms. The duplex lathe, with one tool acting in front and the other behind the work, is also found to be a very useful arrangement for turning long shafts, cast-iron rollers, cylinders, and a great variety of work, where a quantity of the same kind and dimensions has to be turned. See DUPLEX-LATHE.

The *slide-rest* is the invention of General Sir Samuel Bentham, and is the precursor and original of the planing-machine for metal. General Bentham is the inventor of the planing-machine for wood, patented in England in 1791. It seems to have been a reciprocating machine, acting after the manner of a hand-planer. He afterward invented the planing-machine with circular cutters. See PLANING-MACHINE.

Since the beginning of the century, numerous improvements in the lathe, some of them valuable, have been made the subjects of letters-patent in this country and in England; so numerous, indeed, are they that a bare recitation of their titles would fill considerable space. The more important improvements will be found described in the book called "The Lathe and its Uses; or, Instruction in the Art of turning Wood and Metal," copiously illustrated, published by Wiley & Co., New York; and in "Turning and Mechanical Manipulation," by Joseph Holtzapffel, an English work not republished in the United States.

Lathes are known by various names, according to construction, mode of driving, etc.

The *bar-lathe* has a single beam or shear, generally of a triangular shape. On this the heads or puppets slip.

The *bed-lathe* is the usual form, and has two parallel shears.

The *center-lathe* has head and tail stocks, which afford centers for each end of the work turned.

The *chuck-lathe* supports the work being turned, by means of a grasping tool or socket on the mandrel of the head-stock.

The *foot-lathe* is driven by a treadle.

The *geometric lathe* is an instrument for producing wavy or eccentric patterns with a general concentric arrangement. See GEOMETRIC LATHE.

The *hand-lathe* is driven by a crank or bow, and is of small size, for the bench or table.

The watchmaker's lathe is a small bench-lathe, sometimes having pivot centers, on which the work is turned by a bow, and sometimes a *hand-lathe* or a foot-lathe of small proportions.

The *last*-lathe is a LATHE FOR TURNING IRREGULAR FORMS (which see).

The *mandrel-lathe* supports the work on a spindle, which is attached to the axle of the head-stock, or on the head and tail centers, according to circumstances.

The *pivot*-lathe is a small bench-lathe whose centers are the ends of rods clamped in the heads and not partaking of the revolution.

The *pole-lathe* supports the work on puppets, and the cord passes from the treadle two or three times round the work, and then upward to a spring-bar. See Figs. 2830, 2831.

The *power-lathe* is driven by horse-power, water, or steam.

The *rose-engine* lathe is a form of the geometric.

The *spindle-lathe* has a rotating axis in the head-stock, to which the work is attached.

The *spoke-lathe* is a LATHE FOR TURNING IRREGULAR FORMS (which see).

The *turn-bench* is a small portable lathe for the work-bench or desk.

The parts of a lathe are, —

The *bed*, *sheers*, *cheeks*, *sides*, on which the puppets slide. The *puppets*, which form the *head-stock* and *tail-stock*. The *mandrel*, or live spindle of the live head, and on which is the speed-pulley. The centers on the *live* or *front spindle*, and the *dead* or *back spindle*, respectively, on which the work is turned.

The *fly-wheel* (of a foot-lathe), on which is the cord passing to the *speed-pulley* of the head-stock.

The *treadle*, or *foot-board*, to which the power is applied.

The *collar-plate*, *cone-plate*, *face-plate*, *chuck*, or other means of connecting the work.

The *rest* for the tool.

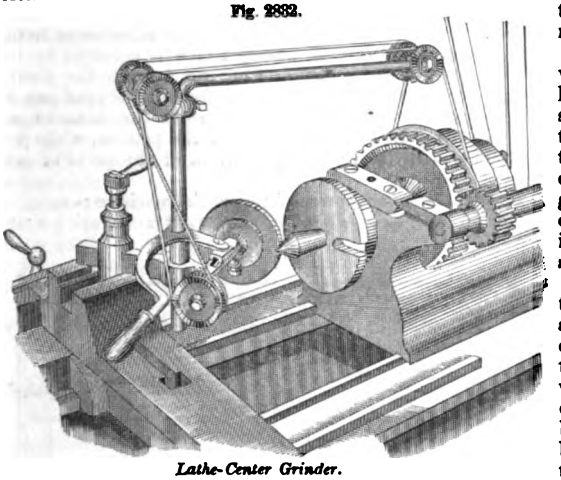
2. (*Weaving.*) The wooden frame beam which forces up the weft. The *lay* or *batten.*

It may consist of these parts : —

The *swords ;* two upright laths at the ends of the race.

Fig. 2832.



Lathe-Center Grinder.

The *lay-cap* or *pull-to ;* the top bar by which it is handled.

The *reed, sley,* or *slay,* which has parallel slips of metal or cane which separate the warp-threads and batter against the weft.

The *race,* or shuttle-track.

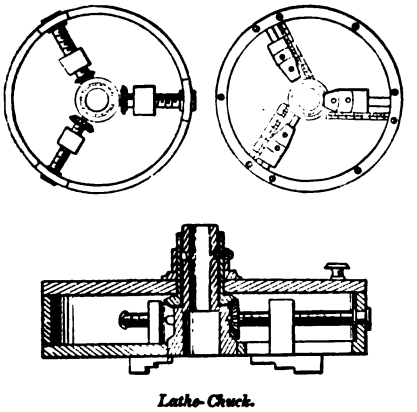
The *shuttle-boxes,* at the ends of the race.

The *picker, pecker,* or *driver,* which strikes the *fly-shuttle* and drives it along the *race* through the *shed,* which is formed by the decussation of the warp.

The *picker-cord,* which jerks the *picker.*

Lath-cen'ter Grind'er. An attachment to a lathe for truing the hardened live center *in situ,* by means of an emery-wheel rotated by a band conducted over idlers from the lathe-pulley.

Fig. 2833.

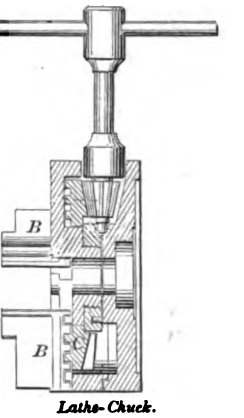


Lathe-Chuck.

Lathe-chuck. One for holding work to the live mandrel, or a mandrel between centers of a lathe.

Fig. 2833 shows a universal chuck, in which the gear is placed at the center of the chuck, and pinions are arranged at or near the inner end of the driving-screws. The gear-hub is retained in place by a set-screw made to play in a groove in the gear-hub. Scales on the face-plate serve as guides in setting an eccentric, and also in adjusting the jaws at the right point.

Fig. 2834.



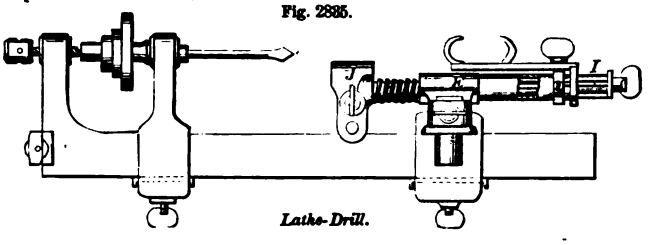
Lathe-Chuck.

The right-hand view is on an enlarged scale, and shows the dogs, the screws, and the back-plate, carrying the bevel-gear which meshes with the pinions on the dog-screws.

In Fig. 2834, the dogs *B B* are advanced or receded by the action of a wheel *C* with a spiral worm on its face and a bevel-gear on its back, actuated by the bevel-pinion which is turned by the key. See also CHUCK.

Lathe-dog. A piece on a mandrel or on work in a lathe, which, by contact with a pin on the face-plate of the live head, is caused to turn the work. See DOG.

Fig. 2835.



Lathe-Drill.

Lathe-drill. A bar-lathe arranged as a horizontal drilling-machine. The work is grasped by the vise *J,* and fed to the tool by the slipping of the piece *I* in the tube *E.*

Lathe for turn'ing Ir-reg'u-lar Forms. Previous to the present century, we read in the works of Condamine, De la Hire, and Plumier of lathes adapted to turn irregular forms.

De la Hire shows how all sorts of polygons may be made by the lathe, and Condamine shows how a lathe may be made to turn all sorts of irregular figures by means of tracers moved over the surface of models and sculptures, medals, etc.

Plumier's work enters extensively into the art of turning. Among other machines, he describes the slide-rest in combination with a planing-machine. This he calls an English invention.

In addition to the citation of these authors, we may refer to a number of elaborate machines made by Sir Samuel Bentham, 1793, and Joseph Bramah, 1802.

The machine invented by Brunel for making the groove around ship's blocks for the insertion of the ropes by which they are attached to the rigging has a revolving disk of brass with two cutters. It trav-

Digitized by Google

erses around one side of the block, receiving its direction from a shaper placed parallel thereto, making the groove deeper at the ends than at the central part, where the sheave-pin is inserted.

The parent of all recent machines of this kind is, however, the lathe invented by Thomas Blanchard of Philadelphia, and patented by him September 6, 1819.

This lathe for turning irregular forms contains the generic idea of all machines for duplicating shapes by using a model in conjunction with a blank, the outline of the model guiding the cutting-tool to produce a duplicate from the blank.

This ingenious device may be said to have wrought a complete revolution in that branch of wood-working to which it appertains. Originally applied to turning lasts, it has since been employed to shape the most difficult forms, gun-stocks for example, which it was formerly imagined could only be produced, and in a far less finished manner, by the drawing-knife, the gouge, and the chisel.

Fig. 2836, *A* shows a plan of the machine as originally patented. *a* is the frame, *b* a drum driving the pulley *c*, whose shaft serves as a common axis to the rapidly rotating pattern-wheel *d* and cutter *e*. These are maintained respectively in contact with the pattern *f* and the roughed-out block *g*, which is to be turned, so that as the former moves transversely back and forth the latter follows its motions.

The common axis of the wheel and cutter is caused to recede or advance, as projections or depressions of the model are brought in contact with the pattern-wheel, by means of a spring. A screw *h* produces a longitudinal movement.

It is obvious, as stated by the inventor in his specification, that various alterations in the positions of the working parts, with relation to each other, may be made without interfering with the general principle.

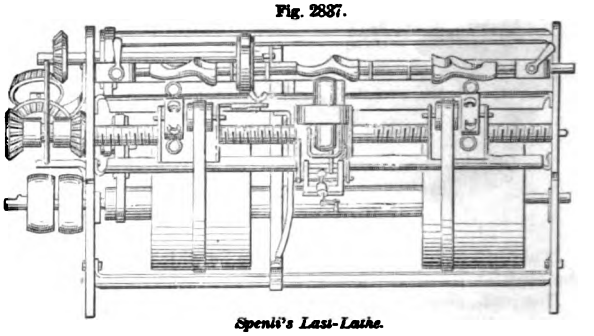
B, Fig. 2836, is a recent form of lathe of this description, all the parts of which are of iron.

In Spenli's lathe, a right and left last are turned at the same time in the same lathe, and from a single pattern, which may be larger or smaller than the last produced. The cutter-heads are traversed by the right and left hand screws of the single spindle, so as to simultaneously advance or recede from the central wheel, which is actuated by the pattern-last. By shifting the bolt in the slotted lever, the motion of the pattern-wheel head can be accelerated or retarded to make the lasts respectively smaller or larger than the pattern, while preserving the relative proportion of the parts of each last.

There are several forms of the machine :—

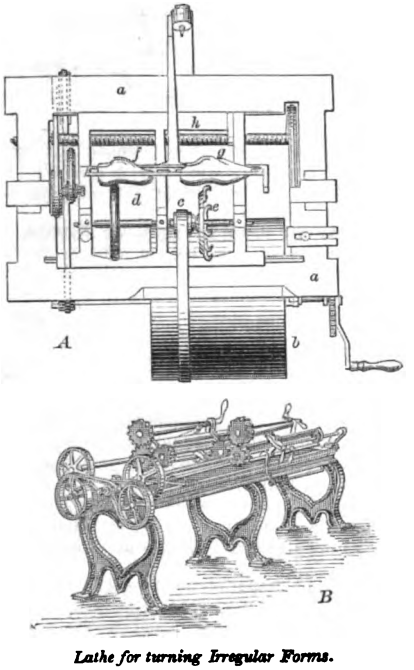
1. The slowly revolving model and work ; a rapidly rotating cutter acting on the work, and regulated as to proximity to the axis of the work by a tracer which rests against the rotating model.

Fig. 2837.



Spenli's Last-Lathe.

Fig. 2836.

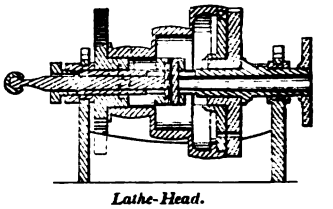


Lathe for turning Irregular Forms.

2. Rapidly rotating work and a rapidly rotating cutter, whose proximity to the work is regulated by a templet.

3. Rapidly rotating work and a cutter actuated by a templet.

Fig. 2838.



Lathe-Head.

Lathe-head. The poppet-head which contains the mandrel, on which is a cone-pulley for the belt and a means for attaching a face-plate or chuck for the work.

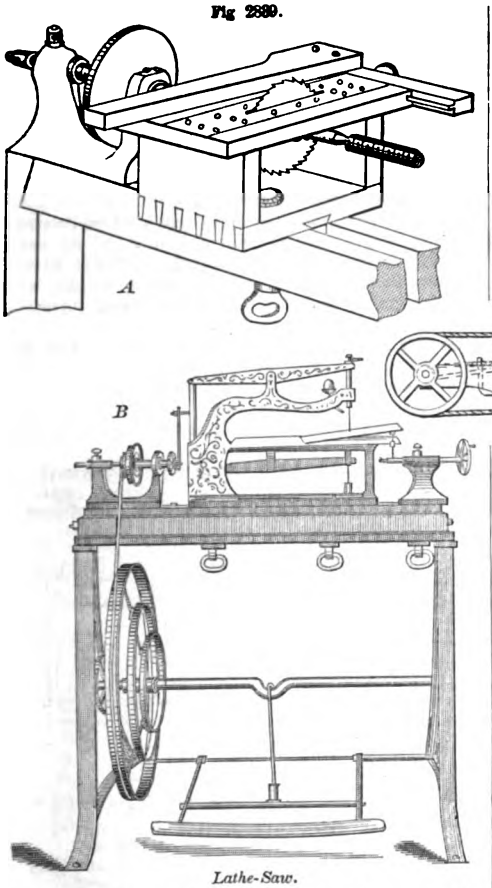
Lathe-saw. For some of the smaller uses of circular saws they may be retained on the mandrel, supported on the lathe centers, as shown at *A*, Fig. 2839, while a bench is arranged upon the shears of the lathe. The wooden box is secured by a screw-clamp beneath the shears, and the platform is hinged to the back of the box, the saw projecting through a slot in the platform.

A *fence* can be arranged on the platform to act as a gage and guide in slitting a number of pieces to a size. A guide against which the work may be held, so as to present it at any angle to the saw, is a convenient adjunct.

B (Fig. 2839) shows a small fret-saw mounted on an ordinary lathe. The table is adjustable in hight, so that, being half an inch above the lathe-center, the saw will have an inch stroke, or a quarter of an

Digitized by Google

Fig 2839.

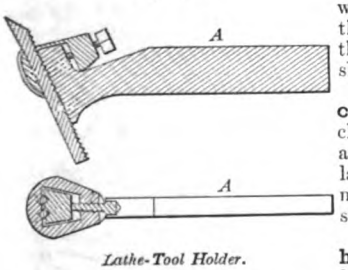


Lathe-Saw.

inch will give a half-inch stroke, and so on. The post uniting the back ends of the levers is connected to a wrist on the face-plate of the lathe-mandrel.

Lathe-tool Hold'er. A socket or holder for a lathe-tool, having a shank *A* which is held by the set-screw on the post of the slide-rest.

Fig. 2840.

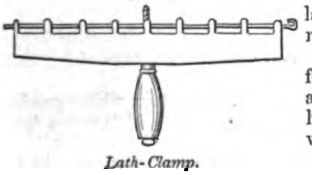


Lathe-Tool Holder.

Lath'ing-clamp. A clamp to hold a set of spaced laths while nailing to the studding.

Lath'ing-hammer. A hatchet, whose *bit* and *poll* present a straight line, so that the bit does not interfere with nailing up laths in corners of rooms.

Fig. 2841.



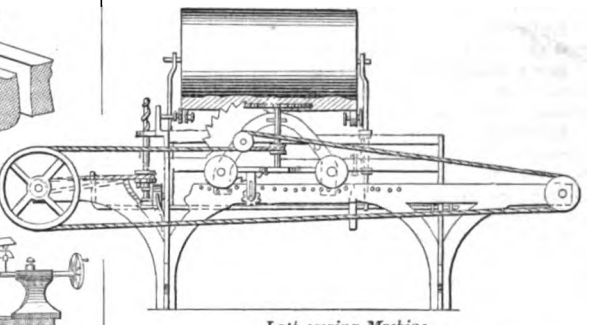
Lath-Clamp.

The bit is used for cutting lath to a length, and it has a notch for withdrawing nails.

Lath-nail. A small cut nail (about 4 *d.*), for fastening laths to studding.

Lath-saw'ing Ma-chine'. One for sawing lath from the board or the bolt. The cylindrical log is mounted on journals upon gravitating guide-bars, and supported and rotated by rollers. The laths are sawn from its periphery by saws cutting rectangularly to each other.

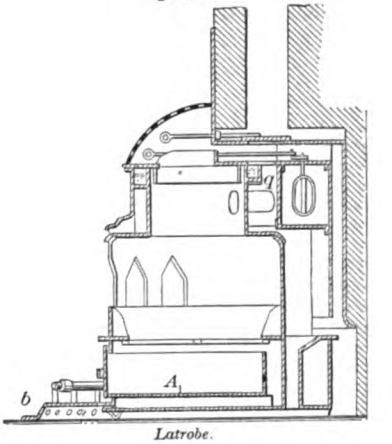
Fig. 2842.



Lath-sawing-Machine.

La-trobe'. A form of stove which sets into the fireplace of a room, has a projecting ornamental front, and is arranged for heating floors above. In the example, the furnace portion has a means of direct access to the flue in kindling fire or urging a strong draft, the lower damper shown in the cut, which moves the butterfly-valve in the partition between

Fig. 2843.



Latrobe.

the downcast flue and the upward or reverting flue, which conducts the smoke to the chimney. The upper damper governs the opening by which the air heated by the stove is conducted to the hot-air flue and led upward to the registers of the rooms on the upper floors. The lower plate *A* is elevated above the floor, and the air heated beneath it is also conducted to the room at the passages leading to the upper rooms. The air is admitted through a perforated extension-plate *b* of the base-plate. *q* is a vessel for water, which is evaporated and mingles with the hot air which passes to the room or rooms.

Lat'ten. Thin metal. Metal in sheets.

In the Middle Ages, a thin plate of brass or bronze, used for cutting into crosses, bending into candlesticks, etc.

Digitized by Google

Black-latten is brass in milled sheets, used by braziers and for drawing into wire.

Shaven latten is a thinner article.

Roll-latten is polished on both sides, ready for use.

Latten-wire is wire made from latten-plate. It was thus made before the invention of wire-*drawing*.

Lat'ten-wire. Wire made from strips of latten.

Lat'ter-kin. (*Plumbing.*) A pointed piece of hard wood, used for clearing out the grooves of the *cames* in *fret-work* glazing.

Lat'tice. A structure of crossing laths or bars, as a *lattice-window*, *lattice-girder*, etc.

Lat'tice-bridge. A bridge supported by a girder whose web consists of diagonal crossing-pieces. See IRON BRIDGE.

Lat'tice-gird'er. A girder consisting of two horizontal bars united by diagonal crossing-bars. See IRON BRIDGE.

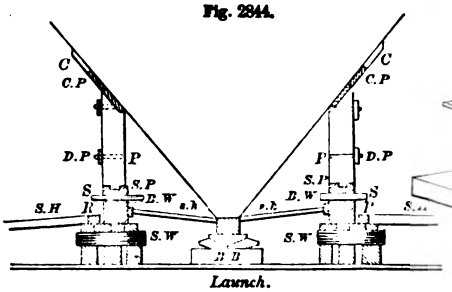
Lat'tice-truss. One having horizontal chords and inclined intersecting braces.

Lat'tice-win'dow. A window formed of leaden frames, called *cames*. The panes are usually diamond-shaped, and are set with an acute point upward.

Launch. 1. (*Shipbuilding.*) A term comprehending the apparatus for launching a ship.

S W, the *slip-ways* or *sliding-ways*. The structure above them, giving temporary support to the ship, is the *cradle*. The *slip-ways* are parallel, inclined platforms of timber, firmly founded on the floor of the slip, and kept steady in their positions by shores *S H*. Their slope varies from 1 in 12 for small vessels to 1 in 24 for the largest. The breadth is from three to four feet. The distance apart of the *slip-ways*, from center to center is about one third of the width of the vessel.

Fig. 2844.



Launch.

R R are ribbands to act as guides.

B W are the sill-pieces of the cradle-frame, and are termed *bilge-ways*. Their length for wooden ships is about five eighths of the length of the ship.

P, the *poppets*, are posts rising from the sole-pieces *S P*, which rest on the *bilge-ways*.

S, the *slices*, are wedges by which the *cradle* and ship are lifted clear of the *building-blocks B B*, to prepare for launching.

The upper ends of the poppets *P* rest against planks *C P*, which are prevented from slipping by means of the *cleats C*, bolted to the side of the vessel.

D P, the *dagger-planks*, are longitudinal ties by which the *poppets* are stayed.

S H, *s h*, are outer and inner shores, by which the *bilge-ways* are held to their places on the *sliding-ways*.

2. (*Nautical.*) The largest boat belonging to a ship of war. It is only used for service which cannot be performed by the smaller boats, being hoisted in board and kept on deck just abaft the foremast, where it serves as a receptacle for lumber and stores. In large men-of-war the launch is sometimes decked over, and is capable of mounting several light guns. The corresponding boat of merchant vessels is called the *long-boat*.

The launch is from 30 to 40 feet long, having a beam from .29 to .25 of its length. It has 10 or 12 oars, and is carvel-built.

Steam-launches are now used in the navy, and as despatch and revenue boats.

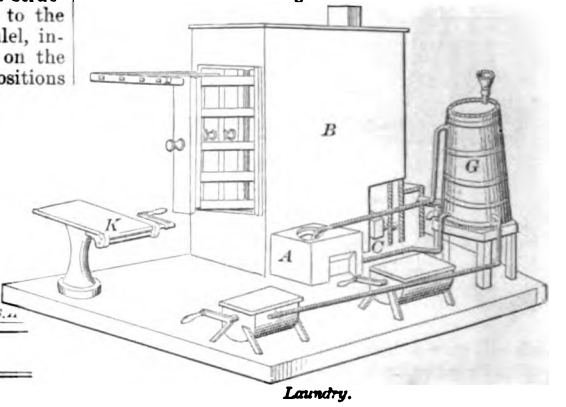
Launch-en'gine. Launch-engines generally consist of a boiler with engines attached thereto, and are used for propelling the launches of large ocean steamers in shallow harbors, etc. Such launches are used for general service, the transportation of men and stores, and as despatch-boats.

Laun'der. (*Mining.*) A wood water-gutter or pipe. A trough for conveying water to a stamp-mill or other hydraulic apparatus for comminuting or sorting ore.

Or a trough or box to receive the slimes from the stamps.

Laun'dry. An apartment arranged for washing, drying, starching, mangling, and ironing clothes, as in the example, which has a boiler *A*, drying-closet *B*, water-reservoir *G*, mangle *K*, and washing-machines.

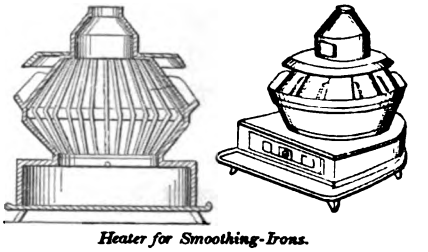
Fig. 2845.



Laundry.

Laun'dry-heat'er. A stove adapted to the uses of a laundry, especially for heating smoothing-irons, having an inclined heating-surface with a shelf.

Fig. 2846.



Heater for Smoothing-Irons.

Law-bind'ing. (*Bookbinding.*) A plain style of binding in leather of the natural tan-color; calf or sheep.

Lawn. 1. (*Fabric.*) A very fine white goods, cotton or linen, finer than *cambric*; of an open texture, plain or printed.

White lawn is part of the flowing dress of a bish-

Digitized by Google

op. It has the odor of ecclesiastical preferment, and, according to Pope, of sanctity also, which is not always the same thing.

"A saint in *crape* is twice a saint in *lawn*."

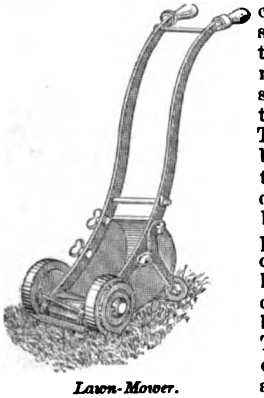
A certain Right Reverend Lieutenant-General was felled a few years since by a round shot. His three-starred coat hid the lawn.

2. (*Porcelain.*) A fine sieve of silk, 300 threads to the inch, through which *slip* for porcelain is strained, to insure an impalpable, creamy fluid. See SLIP.

3. A smooth, grassy surface in the vicinity of a house.

Lawn-mow'er. A machine for cutting sward.

Fig. 2847.

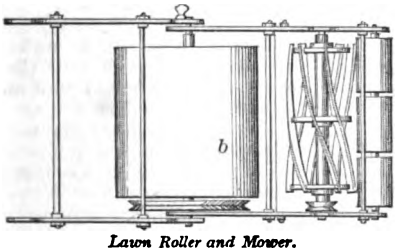


Lawn-Mower.

One form of lawn-mower has a revolving cylinder, armed with spiral knives, which rotate in contact with the rectilinear edge of a stationary knife, placed tangentially thereto. The cylinder is rotated by gear connection to the supporting and driving wheels. The blades of grass are nipped between the edges of the spiral and straight knives, are cut off and delivered into a trough behind the cylinder. The machine is made of different sizes, to cut a swath of from 18 to 36 inches, and is pushed before him by the gardener.

Fig. 2848 has a roller *b* and a set of spiral knives, which cut against a straight edge, near the supporting rollers, which support the hinged portion when

Fig. 2848.

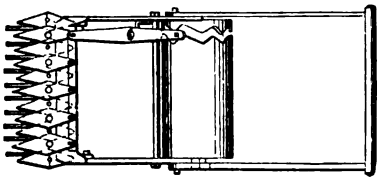


Lawn Roller and Mower.

the mower is brought into action. The mower may be thrown up and over the handle end when the machine is to be used for rolling only.

In Fig. 2849, a row of knives are vibrated by the arm which is oscillated by the zigzag on the roller.

Fig. 2849.



Lawn-Mower.

Lay. 1. (*Rope.*) The direction in which the respective *yarns*, *strands*, etc., are wound in forming them into a *rope*, *hawser*, *cable*, etc.

Hemp is *laid-up right-handed* into *yarns*.

Yarns are *laid-up left-handed* into *strands*.

3-*strands* are *laid-up right-handed* to form a *hawser*.

3-*hawsers* are *laid-up left-handed* to form a *cable*.

The terms signifying the respective forms are, *single-laid*, *hawser-laid*, *cable-laid*.

2. (*Cotton-manufacture.*) *a.* 120 yards of yarn. The yarn is wound on a reel 4½ feet in circumference, 80 revolutions of which make a *lay*, and 7 lays make a *hank* of 840 yards. This is the length of a *hank* of any grade of cotton yarn. The yarn is rated by the number of hanks which go to make up a pound. Nos. 40 to 50 are ordinary *throstle* weaving; Nos. 300 to 400, ordinary mule weaving. By the mule much higher numbers have been reached. No. 700 being exhibited in 1853. See YARN; HANK.

The *lay* is also called a *rap* or *ley*.

3. (*Flax-manufacture.*) 300 yards of linen yarn. See LEA.

4. (*Wool-manufacture.*) A quantity of wool or other fiber in a *willow* or carding-machine.

5. (*Weaving.*) The *batten* or *lathe* of a loom, by which the weft-threads are beaten up in the shed to compact them against their predecessors. See LATHE, 2.

Lay-cap. (*Weaving.*) A slat which lies on top of the *reed*, and which is grasped by the hand in working the *lathe* or *batten*.

Lay'er. 1. (*Tanning.*) A pit containing a strong solution of tannin; used for hides near the conclusion of the tanning process. A *bloomer*.

The pits containing the weaker solution, used in the earlier portions of the process, are termed *handlers*.

2. (*Leather-manufacture.*) A welt or strengthening strip.

3. (*Husbandry.*) A limb laid a part of its length beneath the surface-ground, that it may strike root.

4. *a.* A course of stone or brick.

b. A thickness or bed of puddled clay in a canal.

c. A bed of mortar or cement.

Lay-fig'ure. An artist's model. A jointed figure to clothe in imitation of the human body.

Lay'ing. 1. (*Rope-making.*) The twisting of three (or more) yarns into a *strand*, or of three strands into a *rope*. The rotating hooks by which the *strands* are made are rotated in a direction contrary to the twist of the separate *yarns*. The *rope* again receives a *twist* the opposite of the *strands*. See LAY; ROPE.

2. (*Plastering.*) The first coat of plastering in two-coat work. The surface is made rough by a broom to form a key for the next coat.

The first coat of *three-coat work* is called the *rendering*.

Lay'ing-hook. (*Rope-making.*) One of the iron hooks on the poles of a ropewalk in which the strands are laid as twisted.

Lay'ing-ma-chine'. A machine for laying up yarns into rope. See ROPE-MAKING MACHINE.

Lay'ing-on Tool. (*Bookbinding.*) The tool wherewith the gold-leaf is laid on to the cover or the edge.

Lay'ing-top. (*Rope-making.*) A conical piece of wood placed between the strands, and gradually receded as the lay progresses, in order to keep the twist well to the point at which the strands diverge, and not let it degenerate into a slack twist throughout the length of the strands in the walk.

Digitized by Google

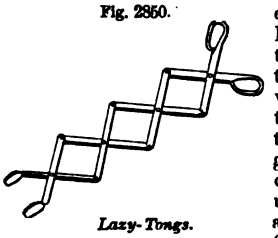
Lay-race. (*Weaving.*) The shuttle-path on the lay of a loom. The *shuttle-race.*

La'zy-back. (*Vehicles.*) A high back-bar to a carriage-seat. It is sometimes made shifting, so as to be removed at will.

La'zy-jack. A lifting-device of compounded levers on the principle of the *lazy-tongs.*

La'zy-tongs. A system of levers, moved by the impulse communicated to the first pair. It is called the lazy-tongs, inasmuch as the grippers are advanced at the same time they are closed together, reaching and grasping simultaneously. The motion is used in many appliances and machines. Gates, guards between platforms of cars, elevators for fire-ladders, drop-lights, and extension gasaliers, and others which will appear occasionally in this work under their respective heads.

Fig. 2850.



Lazy-Tongs.

Lea. 1. (*Flax-manufacture.*) A measure of 300 yards of linen yarn.

Table.

300 yards, 1 *lea.*
10 *leas*, 1 *hank.*
20 *hanks*, 1 *bundle* = 60,000 yards.

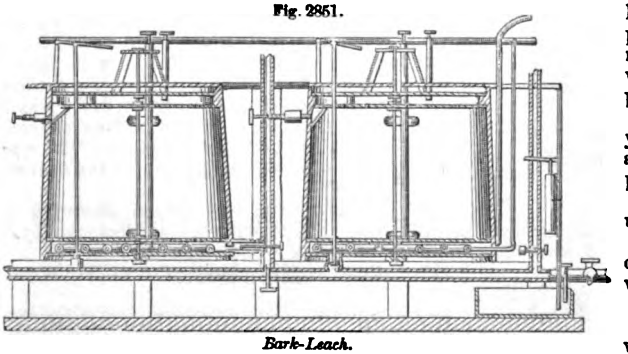
Also called a *lay*, *ley*, *rap*, or *cut.*

2. (*Cotton.*) 120 yards of yarn.

3. (*Weaving.*) *Leas.* One of the alternate sets of threads into which a warp is divided. The whole series is divided into alternate sets, which are to be placed in the loops of the respective *heddles*, so as to be raised and depressed alternately to form the shed in which the shuttle traverses. See WARPING-MILL.

Leach. A vat or chamber in which a body is placed, in order that its soluble portions may be removed by soaking and infiltration. It is a filtering operation in which the liquid removes the soluble matter from the material through which it flows. A familiar instance is the ash-leach.

Fig. 2851.

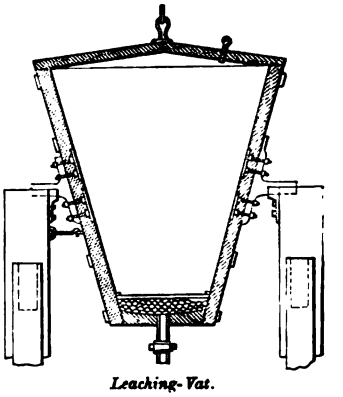


Bark-Leach.

In the bark-leach, the bark is contained between two perforated horizontal partitions in the leach, the lower one having a coiled steam-pipe for heating the contents. The menstruum may be forced through the bark in either direction by means of pipes furnished with valves to determine the said current.

Leach'ing-vat. A vessel in which a material containing a soluble portion is exposed to the action of a solvent, say water, which dissolves and carries away the said portion.

Fig. 2852.



Leaching-Vat.

The example shows the form for leaching-vat used in the process of chlorinating gold. This is made of two-inch plank and painted inside with pitch. Leaden discharge-cocks are placed at the bottom, and pieces of quartz laid loosely under the perforated earthenware false bottom, which is arranged so that it will remain in the vat when the latter is overturned. The vat is closed air-tight by means of a thick lid pressing upon a rubber band on the rim. A pipe inserted into the lid leads the chlorine gas from one vat to another, so that it passes consecutively from one to another in the row until it is exhausted. The vat is charged with auriferous slimes, the lid fastened, gas admitted. After the gold is dissolved, water is admitted, carrying off the chloride of gold to a vat. When the ore is thoroughly leached, it is discharged into a car by overturning the vat, and is then driven off and dumped outside the works.

Lead. 1. A soft, bluish-gray, fusible, ductile, heavy metal. Volatile above red heat. Equivalent, 103.5; symbol, Pb.; specific gravity, 11.44; fusing point, 612° F.

It usually occurs as *galena* (sulphide of lead), and is easily reduced. This is, —

Picked; to remove trash.

Broken and washed; to separate earthy and siliceous matters.

Roasted; a portion is moderately heated to convert it into the sulphate, and then mixed with an unroasted portion. The two are then well roasted to eliminate the sulphur. See LEAD-FURNACE.

The protoxide of lead is litharge, a yellow powder much used in the arts, and as a glaze for pottery and a component in flint-glass.

A compound oxide, red lead, is used as a pigment and a flux.

The white-lead of commerce is a carbonate of lead, and a valuable white paint. See WHITE-LEAD.

The uses of lead are manifold.

Its tractability, softness, fusibility, weight, and cheapness render it particularly suitable for bullets, shot, packing of projectiles, etc.; lining of cisterns, boxes, gutters, and numerous other articles; and it is specially useful in type metal, in all solders and fusible alloys (see ALLOYS), as well as in the composition of various articles of use and ornament, domestic and mechanical.

The lead of commerce is divided into: —

Pig-lead.
Sheet or *milled* lead.
Lead pipe.
Shot.

Digitized by Google

White-lead. *Chromate of lead.*
Litharge. *Red*-lead.

Lead was known in old times. "They sank as lead in the mighty waters," is a part of the triumphal song of Miriam, 1491 B. C. Job refers to its use for writing-tablets, "An iron pen and lead." A work of Hesiod was preserved for many centuries scratched on leaden tablets. "Iron, tin, and lead" were enumerated by Ezekiel as among the commercial objects of the Tyrian trips to Tarshish. The mines of the Cassiterides, that gave the tin to alloy with copper for the vessels of the temple at Jerusalem, gave also lead to the brave merchants of Phœnicia. The Romans used sheet-lead largely for water-pipes.

2. (*Sounding.*) An ordinary *hand-lead* is a mass of lead, weighing from 7 to 11 pounds, attached to a line of 20 fathoms length. The line is marked at 2, 3, 5, 7, 10, 13, 15, 17, and 20 fathoms; the numbers between the *marks* are called *deeps*. Thus, "by the *mark twain*," "quarter less 5," "and a half 7," "by the *deep* 9," indicate those depths respectively.

The *deep-sea lead* weighs 25 to 30 pounds, with a much larger line marked at every 10 fathoms. See SOUNDING.

3. (*Printing.*) A thin plate of type-metal, less than type-hight, and used to separate lines in printing.

Spaces separate the letters or words.

4. (*Knitting-machine.*) *a.* Solder in which various members are imbedded, and by which they are attached.

b. The tin socket which forms a haft for the knitting-needle.

5. The graphite for filling the grooved cedar staff to form a lead-pencil. See PENCIL.

6. (*Plumbing.*) *a.* A roof covered with sheet-lead.

b. The *came* of the diamond-paned casement.

Lead. 1. (*Sawing.*) The overhang of a saw, to extend the cut throughout the length of the saw and to carry the saw back in the *kerf* during the return stroke.

2. (*Mining.*) A lode or vein of ore.

3. (*Engineering.*) The distance from an earth-cutting to an embankment.

4. (*Steam-engine.*) *a.* An arrangement of the ports of a steam-valve by which steam is admitted in front of the piston a little before the end of the piston-stroke. Also an arrangement of the ports to provide for the escape of the steam from behind the piston before the completion of the stroke.

When on the *steam* side, it is called *outside* lead. When on the *exhaust*, it is *inside* lead. It tends to check the velocity of the piston at the end of the stroke, and allows of the valve being open and ready to admit a larger supply of steam the instant the motion of the piston is reversed.

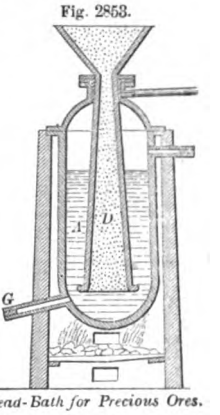
b. (*Lead of the crank.*) The setting of the crank of one engine a little in advance of the right angle to the other; namely, at 100° or 110° in place of 90°. This assists in rendering the motion of the piston more uniform, by moderating its velocity at the end of the stroke.

Lead-bath. A process for the extraction of gold or silver from comminuted ore by exposing it mechanically to molten lead, with which it forms an alloy. The subsequent separation is by cupellation or, with silver, by Pattinson's process. See *infra*.

In reducing silver ores, the ancient Peruvians mixed them with galena or lead in portable ovens. It is still practiced in that country. Quicksilver was well known in Peru among the Incas, but was used to make the pigment vermilion, not to amalgamate the precious metals. Hawks writes, A. D. 1572, that the process of amalgamating silver ores with mercury is being substituted for melted lead. See AMALGAMATOR.

In Bursile's English patent, February 12, 1853, the ore is treated with an amalgam formed by the union of quicksilver in a readily fusible alloy of lead and bismuth, or lead, bismuth, and tin.

Fig. 2853.

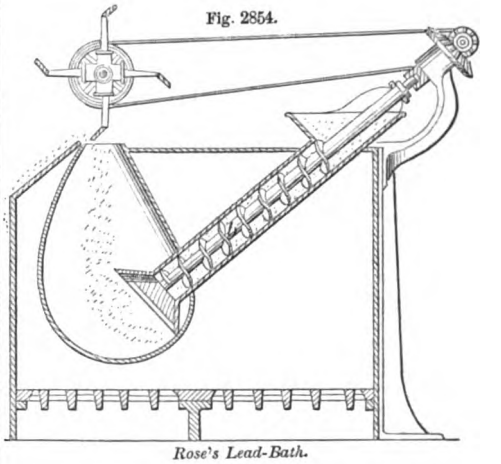


Lead-Bath for Precious Ores.

In Fuller's apparatus, the comminuted ore occupying the central shaft *D* is discharged in a diffused condition beneath the column of lead *A*, which is kept in a molten condition by the furnace beneath. The heavier portion of the alloy is drawn off at times at the pipe *G*. The ore rises through the lead, bringing the particles of gold or silver in contact with the lead, with which they unite. The flow of ore is encouraged by withdrawing air from above the lead by an air-pump. *H* is the discharge-pipe for tailings.

In Fig. 2854, the vessel is suspended in a furnace through which extends an inclined tube, which discharges its contents near the bottom. The tube has a propelling screw having a shoulder and elastic collar at its bearing, and a grinding plate at its lower end, which works against a grinding surface attached to the lower end of the tube. Above the

Fig. 2854.



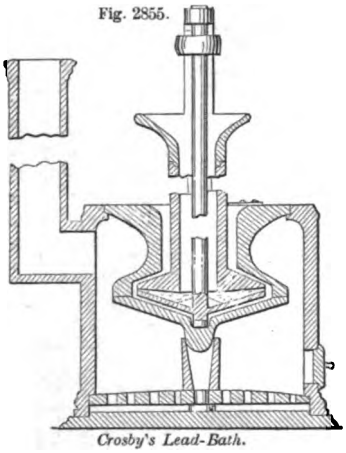
Rose's Lead-Bath.

mouth of the vessel is a wheel which removes the waste ore as it rises to the surface of the molten lead.

In Crosby's apparatus the bulbous vessel contains a lead-bath, and is supported in the furnace. The tubular conductor has a disk on its lower end, against which rotates a grinding-plate attached to the vertical axial-shaft. The ore passes down the tube, is associated with lead which flows through openings in the side of the ladle, and the combined mineral and metal are triturated together between the grinding-surfaces, the precious metals becoming amalgamated with the lead while the refuse mineral rises to the top and is skimmed off.

Digitized by Google

Fig. 2855.



Crosby's Lead-Bath.

Lead-cut'ter. (*Printing.*) A knife for cutting leads which are held in a tray the while.

Lead'er. 1. (*Pyrotechnics.*) A long paper tube of small diameter, enclosing a strand of quickmatch, used for communicating fire rapidly from one point to another. Quickmatch thus enclosed burns much more rapidly than in the open air.

2. (*Nautical.*) A thimble for conducting or guiding a rope which passes therethrough. A *fair-leader.*

3. (*Machinery.*) A *master* wheel or principal wheel in a piece of machinery.

4. (*Printing.*) A row of dots on a line, to lead the eye across the page or column, are called leaders, as : —

Anchor.....page 94.

5. (*Mining.*) A small vein of ore ; indicating proximity of a larger lode, usually leading thereto.

6. (*Surveying.*) The forward one of the two chain-carriers.

7. (*Plumbing.*) A rain-water pipe to conduct to the ground the water collected by the spouting.

Lead'er-hook. A hold-fast hook clasping a *leader* or rain-water pipe, and having its tang driven into the wall of the house.

Lead'ers. Dotted signs for leading the eye across a space. See LEADER.

Lead-flat. A level roof consisting of sheet-lead laid on boarding and joists.

Lead-fur'nace. The furnace by which the ores of lead are reduced to the metallic state. The sulphuret, commonly known as galena, is the principal source from which the pure metal is derived.

The ore having been picked is broken and washed to separate earthy and siliceous matters.

It is then roasted until about half the charge is converted into sulphate of lead, when this and the portion which remains intact are thoroughly mixed together, and the heat rapidly increased, by which means sulphurous-acid gas is driven off and pure metallic lead remains.

The furnace (Fig. 2856) is used in the north of England, and is known as the Scotch furnace. It has a rectangular cavity of masonry, lined with cast-iron. The inclined sole-plate is also of cast-iron, and has an upright ledge at its back and sides, shelving towards the interior, where it passes through the *work-stone* leading towards a pot which receives the molten lead. The tuyere is introduced through the *back-stone*, and the charge is introduced above. The chimney *d* communicates with flues leading to condensing-chambers. Quicklime and powdered charcoal are introduced during the process of reduction, in order to decompose the oxide of lead formed during the operation, and to render the slag less fusible, that it may be the more readily removed. The lead is said to be purer than that obtained by the smelting-furnace, as the heat is lower, and the silver and lead are *sweated out* without reducing the other metals.

Fig. 2856.

Lead-Furnace.

In Carpenter's furnace, steam is used in conjunction with air, the two being introduced either separately or together into the space above the ore.

Lead-glance. Galena. Sulphuret of lead.

Lead-har'ness. That appertaining to the *leading*-horses of a team ; in contradistinction to that for *wheel*-horses, which have breeching to enable them to hold back the vehicle.

Lead'ing-ax'le. An axle ahead of the driving-wheels in British locomotives.

Lead'ing-block. (*Nautical.*) One for guiding the direction of a purchase or rope.

Lead'ing-buoy. (*Nautical.*) A buoy placed as a guide in sailing.

Lead'ing-light. (*Nautical.*) One character of light as displayed for the benefit of seamen on a coast. Two lights are exhibited from two towers ; one may be higher than the other, so as to confer a special characteristic. Certain bearings as to channel are indicated when the lights are seen in one line, the opening of the lights on either side of their conjunction indicating when to tack. Other indications may be given by the conjunction, according to the nature of the case.

Lead'ing-part. (*Nautical.*) The portion of the tackle between the fall and the standing part. It is that portion which passes over the sheaves. The fall is that which, in pulling or easing, does not reach the sheaves.

Lead'ing-rod. One used in draw-boring and polishing the bores of rifle-barrels.

Lead'ing-screw. (*Lathe.*) The longitudinal screw between the *shears* of a lathe, by which the *slide-rest* is moved longitudinally of the lathe-bed. *Lead-screw.*

Lead'ing-springs. The springs fixed upon the leading axle-box of a locomotive-engine, bearing the weight above. (*English practice.*)

Lead'ing-wheel. A wheel of a locomotive-engine, placed before the driving-wheels.

Lead-lights. A form of casement window in which small panes are fixed in leaden *cames*, which are attached to cross-bars called *saddle-bars.*

Lead-line. (*Nautical.*) A sounding-line.

Lead-mill. A circular disk of lead with an abradant powder, and used by the lapidary for roughing and grinding. See LAPIDARY-MILL.

Lead-nail. 1. A small, round-headed, copper-alloy nail, used for fastening on lead-sheets on roofs.

2. (*Nautical.*) A scupper-nail.

Lead-pot. (*Metallurgy.*) A crucible or pot for melting lead.

Lead from Sil'ver sep'a-rat-ing. Pattinson's method (English) of separating lead from silver is an economical substitute for cupellation. It is founded upon the property which pure lead has of crystalizing out of a solution of silver in lead. The argentiferous lead being fused is allowed to cool slowly, solid crystals of nearly pure lead are first formed, and are separated by an iron strainer from time to time, the melted remainder becoming still richer in silver. At Beaumont's works, Allenheads, Northumberland, the process is conducted in hemispherical, cast-iron pans, each holding about 3 tons of metal and heated by a fire beneath. The process is several times repeated, and the remaining metal is treated by cupellation.

Argentiferous lead ores containing only 3 ounces

Digitized by Google

of silver to the ton can be profitably worked for the silver by this means, while 20 ounces of silver to the ton scarcely paid when treated by the process of cupellation. See also CUPELLATION; PATTINSON'S POTS; LEAD-BATH.

Lead-pen'cil. A marking and drawing instrument, made by enclosing a slip of graphite (commonly called *plumbago* or *black-lead*) in a casing of wood. This is generally round or hexagonal, but large pencils for the use of carpenters and others are sometimes made oval in section.

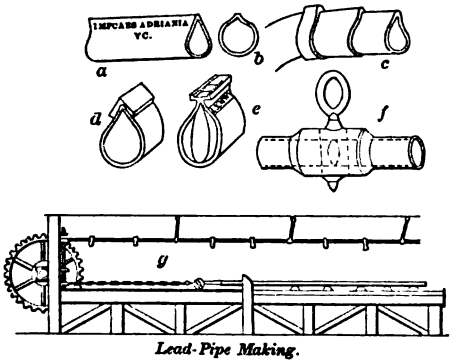
Graphite is generally ranked as a native carburet of iron, but the proportion of the latter metal is so small that it may be considered nearly a pure carbon. It is found in veins, often forming considerable masses. The mines of Cumberland, England, were long the principal source of supply, but are now nearly exhausted. By the old practice, the graphite is first calcined in close vessels at a bright red heat, and is then sawn in slips of the required size, which are inserted in a longitudinal groove in the case, which is formed in two similar parts and grooved by appropriate machinery. The two parts are afterward glued together.

Pencils of the second and inferior qualities are prepared from the dust and other refuse, ground fine and mixed with a kind of fine clay and water, into a paste which is placed in a receiver having an orifice at bottom, of the size and shape of the core. This is cut into proper lengths, straightened, dried at a moderate heat, and afterward baked in close crucibles, when they are ready for insertion into the cases. See GRAPHITE.

America now makes its own pencils. See description of the method pursued at the Dixon Pencil Works, Jersey City, under PENCIL.

Lead-pipe. The use of lead-pipes for conducting water is very ancient. Those of the Romans,

Fig. 2857.



Lead-Pipe Making.

used in their aqueducts, were made out of sheets 10 feet long, and a width proportioned to the diameter required, and averaging about 15 pounds to the square foot. The lead was brought from Britain, and beaten into sheets by heavy hammers. — PLINY.

A sheet 100 inches wide made a pipe weighing 120 pounds to the foot; and would be about 30 inches diameter, allowing for a little lap, were it cylindrical.

The sheets of lead were soldered by the assistance of tin and rosin, the sides being brought flatly together, exposing both edges outside and giving a *pear*-form to the section. Over the joint was soldered a capping ridge, and the whole was hooped around with straps of lead. *a b c d e* show the forms of pipe found at Lyons. Metallic cocks like the modern were used, as seen at *f*.

"Abderahman Ben Alhakem (d. A. D. 852) constructed the Rusafa or embankment along the edge of the river at Cordova, caused water to be brought from the mountains in tubes of lead, and gave orders for the building and erection of numerous fountains in different quarters of the city, with baths of marble." — CONDÉ.

Leaden pipes were used in England as early as A. D. 1236, and Henry III., about 1270, granted the citizens of London the liberty to convey water from the town of Tyburn to the city, by pipes made of lead. A leaden cistern, built round with stone, was erected in 1285. The length of lead-pipe then laid down, from Paddington to the Cross in Cheapside, was 1,096 rods. Cisterns and supply-pipes of lead were numerous in the fifteenth century. The art of casting them was invented by Rev. Robert Brooke, 1539.

In 1582, the water-works of London Bridge were established by Peter Morice, and the water distributed by lead-pipes to certain parts of the city.

In 1613, the New River, an open aqueduct 40 miles long, and having a fall of 3 inches to the mile, was finished by Sir Hugh Middleton, and the water was distributed by wooden mains and leaden branches. In 1804, cast-iron pipes were substituted for the wooden mains.

Lead-pipe is made by *casting*, *drawing*, *pressing*, and *rolling*.

It may be cast in lengths in an ordinary *core-mold*, or consecutive lengths may be cast together by pulling out the core, opening the mold, shifting the pipe along *nearly* its length, replacing mold and core, and then pouring again.

In *drawing* lead-pipe, —

The lead is cast in an iron mold upon a rod of the intended bore, leaving the metal four or five times the thickness it is intended to be eventually. The pipe, with a triblet or mandrel inserted, is then drawn through openings in steel plates of gradually decreasing diameter, which reduce it to the thickness required. When power is applied, the chain winds upon the drum and hauls a little carriage which runs on ways, and has a double claw to engage the head of the mandrel. The perforated steel plate or *whirtle* is held in a cross-bearer above the bench. This mode is shown at *g*, Fig. 2857, and is described in Wilkinson's specification, English patent, 1790.

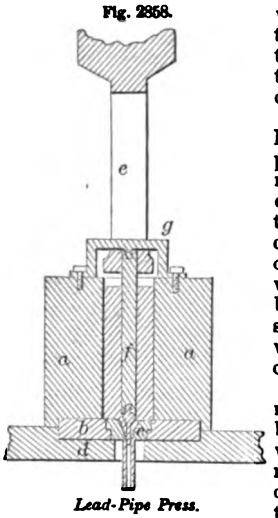
Instead of the plate, a series of rolls may be employed, gradually diminishing in size, successively reducing the diameter of its exterior, while the mandrel maintains the uniformity of its bore.

The first machine for *pressing* lead-pipe was patented in England by Hague, in 1822. The melted lead was forced through a circular throat whose axis was occupied by a mandrel. The lead was driven through at such a rate that it solidified by exposure to cold surfaces. By another plan, the lead is cast into a short heavy cylinder, and the ingot is forced through a throat at the lower end by the exertion of considerable force upon the piston which fits in the cylinder. This would make a round bar, but occupying an axial position in the middle of the throat is a mandrel, which forms the inside of the tube. This mandrel is supported by a bridge-piece in the cylinder, the lead opening to pass it and closing again before reaching the throat; or the mandrel is supported by the piston, which prevents the cleavage and obviates the necessity for rejunction of the metal. A large number of patents have been granted for machinery for making lead-pipe.

Fig. 2858 illustrates the operation. *c* is the triblet in the holder *b*, which rests on the bed *d*. *f* is a core suspended from the bridge *g*. *e* is the ram,

Digitized by Google

Fig. 2858.



Lead-Pipe Press.

which descends upon the cylinder of lead in the box *a*. The bridge traverses a slot in the descending ram.

Lead pipes of great length are formed by pressing the molten metal, contained in a cylinder having a tightly fitting piston connected with the ram of a hydraulic press, which forces the metal between a tube and a solid mandrel; after which it may be coiled on to reels.

Titus's mode of making lead-pipe is by the pressure of a vertical column of melted lead, of sufficient hight to force the metal past a forming die and mandrel.

Lead-pipe Tin'ning. The first attempts in this direction were by Alderson in England, who patented his invention in 1804, which consisted in putting an interior casing of tin pipe within the leaden one.

Dobbs, in 1820, gave a coating of resin to the lead pipe, and then placed it in a mold, a core being also placed in the center, or axial position. Tin was then cast upon it and within it, the two becoming perfectly united. It is then ready for drawing or rolling, whichever may be preferred.

Warner treats the lead pipe with resin, so as to encourage the junction of the tin, and the pipe is then submerged in a bath of melted tin. The pipe may be bent, and thus drawn continuously through the bath, receiving its coat as it passes. If any part, say the outside, is not required to be tinned, such part is covered with lampblack and size. The film of tin may be very thin and does not detract from the flexibility. Tin melts at about 440° Fah. and lead at 612°, but at the point of junction an alloy is formed which melts at a lower temperature and forms a solder.

The purer the water the greater the liability to contract impurity from the lead. Waters containing chlorides, sulphates, or carbonates, throw down insoluble salts of lead. The oxide of lead formed on the pipe protects the metal. Pure waters dissolve the oxide slowly, and the gradual decomposition and removal eat away the pipe.

Owing to galvanic action, the lead is more liable to corrosion in spots not covered by the tin, and therefore an imperfectly tinned pipe is worse than one of lead. To insure the continuity of the coating, Naylor of New York City has patented a process of drawing a sponge saturated with a flux that protects the lead and assists in the adherence of the molten tin.

M. J. Grand's process consists in forming an ingot of tin and lead, the latter metal being on the exterior. A single crucible suffices for melting both metals simultaneously, the tin being uppermost and separated from the lead by an iron diaphragm. The lead is run first into a rapidly revolving mold having a gate in its axis, and while still liquid the tin is let on. The two metals thus become firmly cemented together, the pipe is drawn out in the usual way.

Leads. 1. (*Printing.*) Thin metallic slips used for spacing lines, etc. Invented by Scheeffer about 1465.

2. A flat roof covered with sheet-lead.

Lead-shav'ing Ma-chine'. A machine for cutting lead into shavings, to be used in the manufacture of white-lead.

A series of rotary knives are, by means of a weight and pulleys, brought into contact with the lower surface of a cylindrical ingot of lead, from which they remove shavings proportionate in thickness to the projection of their edges beyond the box in which they are contained.

Lead, Sheet. Sheet-lead was formerly made by melting pig-lead and pouring the metal on a table having a ledge supporting a roller, which passed over the metal and reduced it to an even thickness. The ledge was all around the table, and determined the thickness of the sheet. The modern process is to reduce an ingot of lead by repeated rollings to the required thickness. This is called in England *milled lead*.

The thin sheet-lead which lines tea-chests is said to be made by pouring a quantity of molten lead upon a flat stone; and upon this, while the lead is yet in a fluid state, a corresponding flat stone is suddenly dashed, the superfluous portion, which is squeezed out around the edges, being afterward trimmed off.

Lead-shot. See SHOT.

Lead-sink'er. (*Knitting-machine.*) One of the devices which alternate with the *jack-sinkers* in the depression of the loops between the needles. The lead-sinkers are all attached to one bar, called the sinker-bar, and are raised or lowered all together. See KNITTING-MACHINE.

Leaf. 1. A relatively thin and wide object having a flat surface; as, —

a. The leaf of a book, having a page on each of its opposite sides.

b. A valve or hinged member of a bridge, table, door, shutter, hinge, or screen.

c. One member of a pair of lock-gates.

d. A hinged platform for a ferry or wharf boat.

e. A tooth of a pinion.

f. One section of a fan.

Digitized by Google

g. A thin sheet of hammered gold.

h. One of the elevating flaps of a rifle-sight.

2. (*Weaving.*) The heddles which are connected to the same shaft, and moved at the same time. (See DRAFT.) The *leaf* is connected with a treadle by a cord. The *number* of leaves is according to the requirements of the pattern, and forms the *set of the draft*; beginning at the back, the *setter* works forward to the front leaf, after which they are again moved in the former succession. Hence we read of a *five-leaf* pattern, an *eight-leaf* pattern. The set of warps which are drawn up by one leaf form the upper part of the *shed* or *shuttle-way*. All the other warps are down for that time, and form the *way* on which the shuttle travels.

Leaf-bridge. A form of drawbridge in which the rising leaf or leaves swing vertically on hinges. One form of *bascule* comes under this description.

Leaf-met'al. 1. Gold-leaf; hammered gold. See GOLD-BEATING.

2. Bronze leaf, or Dutch leaf. The qualities are known as, —

a. Common; soft, reddish color, composed of zinc 1, copper 3.

b. French; harder, less ductile, yellow, larger proportion of zinc.

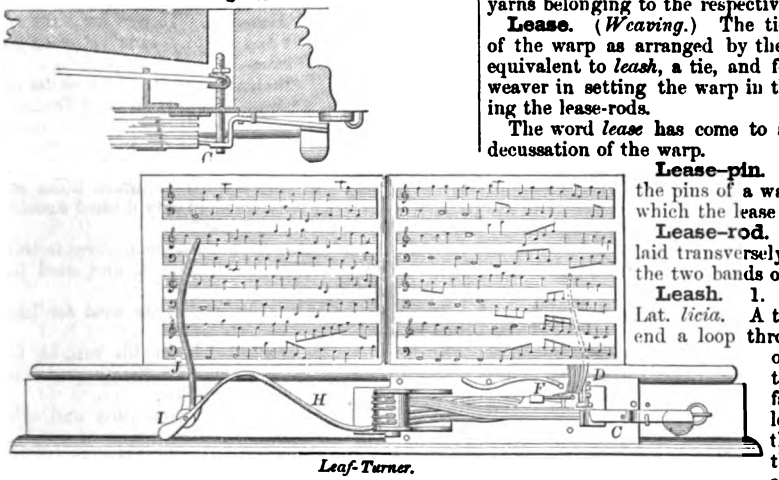
c. Florence; greenish-gold color, still larger proportion of zinc.

d. White leaf; TIN-FOIL (which see).

Leaf-sight. One on the breech of a fire-arm, having a hinged elevating piece (one or more) as a guide for elevation in firing. A *back-sight.*

Leaf-turn'er. A device for turning sheets of music or leaves in a printed book. The fingers *D*

Fig. 2859.



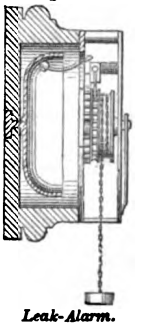
Leaf-Turner.

are inserted between the leaves, and by pressing a key *C* are successively released as required from a catch *F*, allowing a spring to act, carrying the finger from the right to the left hand side of the book, and turning the sheet with it. A free arm *H*, with finger-piece and finger *I J*, serves to keep down the leaves on the left-hand side and to turn back the whole series when a piece of music is finished. The fingers *D* may be pressed downward and held in horizontal position by a catch, so that the leaves may pass freely above them when required.

Leaf-valve. (*Pumping-engine.*) A clack-valve. One hinged or pivoted on one side. A *flap-valve; clack-valve.*

Leak-a'larm. An arrangement by which the accumulation of water in the hold of a vessel is made to sound an alarm to call attention to the leak. It is a regular part of duty on shipboard to sound the pumps, but it is a duty sometimes overlooked. Even when the amount is not dangerous, the accumulation of bilge-water may injure the cargo. See BILGE-WATER ALARM.

Fig. 2860.



Leak-Alarm.

In the example, the water rising in the hold elevates the float, permitting the spring drum to revolve and wind up the chain. This rings the alarm-bell, and moves the index which signifies the depth. As the water falls, the float rewinds the spring.

In another case the staff of a rising float trips an escapement and releases a clapper-alarm.

Leak-In'di-ca-tor. See LEAK-ALARM.

Leak-sig'nal. (*Nautical.*) A device to notify the watch of the rising of water in the hold. See LEAK-ALARM.

Leam. A ditch in a marshy district.

Lean-face. (*Printing.*) Type with unusually thin face-lines.

Lean-to. A shed built against the wall of another structure. A *shed-roof.*

Leap. 1. (*Mining.*) The shifting of a vein. A *fault.*

2. (*Hydraulic.*) A wicker fish-net. A *leap-weel.*

Leap'er. A hollow cylinder with a hook at one end, employed in untwisting old ropes. *Loper.*

Lea-rod. (*Weaving.*) One of the rods placed athwart the warp-threads and separating the *leas*, or yarns belonging to the respective *heddles.*

Lease. (*Weaving.*) The tie around each band of the warp as arranged by the *heck.* The word is equivalent to *leash*, a tie, and forms a guide for the weaver in setting the warp in the loom, and inserting the lease-rods.

The word *lease* has come to signify the plane of decussation of the warp.

Lease-pin. (*Weaving.*) One of the pins of a warping-mill, between which the lease is formed.

Lease-rod. (*Weaving.*) A slat laid transversely across and between the two bands of the warp.

Leash. 1. (*Weaving.*) From Lat. *licia.* A thread having at one end a loop through which a thread of the warp is passed, the other end being fastened to a rod or lever, to which all the other leashes of the same set are also attached. A *heddle.*

2. A leathern thong to hold dogs in couples, to be slipped simultaneously after game.

Leat. An artificial water-course. A mill-race.

Leath'er. The *tanned* or *tawed* skin of an animal.

Tanning was practiced in early ages in some localities, but the references to it are comparatively unfrequent. The Bible has but two notices of it, the girdles wherewith the prophets Elijah and John the Baptist were girded about their loins, — type and antitype.

It is not easy to distinguish in the early mentions of leather what was raw-hide and what was really dressed; even of dressed leather there are many kinds, such as the soft dressing with brains and fat,

Digitized by Google

the tawing with alum and salt, the tanning with bark extract. The latter is the more complicated process.

Leathern dresses and fringes of thongs have long been common in Africa, being described by Herodotus: "The Libyan women wear goat-skins stript of the hair, fringed at their edges and covered with vermilion; and from these goat-skins the Greeks get their word *Ægis*" (goat harness). IV. 189.

It is believed that tanning and dyeing of leather was first practiced in Libya, and thence carried to Egypt, from whence it was carried across the sea to Greece. Leather was stained and embossed in Egypt. The "*rams' skins dyed red*," mentioned in the Mosaic account of the tabernacle, were of African manufacture. The Africans yet excel in this art. Yellow, red, and black *morocco* yet attest it.

The old national dress of the Persians was a close-fitting tunic and trousers of leather. Leathern helmets, cuirasses, belts, shirts, and buskins were common among the nations in the motley army of Xerxes.

The Libyans wore dresses of leather.

The Paphlagonians leathern buskins and helmets.

The Gordian knot was of leathern thongs, and was summarily cut about 330 B. C.

Alum was used in *tawing* leather by the Saracens.

We do not recollect any account of human hide leather, but as raw-hide or parchment it has been utilized. The doors of Rochester (England) Cathedral were formerly covered with the skins of Danish pirates. The same is reported of the doors of the churches of Hadstock and Copford, Essex, England. In the case of the Hadstock church, the microscope has determined the truth of the tradition, for a portion having been removed and tested, it proved to be the skin of a fair-haired person. Upon the north doors of the cathedral at Worcester was formerly nailed the skin of a person who had sacrilegiously robbed the high altar. The doors date from the end of the fourteenth century, and have been long ago removed, but were lately still to be seen in the crypt.

The use of the human hide as a drum-head is mentioned by Byron, who celebrates the desire of Ziska for a posthumous place at the head of the army of Bohemians who attacked the Emperor Sigismond and defeated him, in retaliation for the treachery of the latter in leaving John Huss to the cruelty of his Romish persecutors. Ziska died of the plague A. D. 1425, and left orders that his skin should be made into a drum-head, "to beat the advance," as Byron says.

The varieties of tanned leather are classed as *hides*, *kips*, and *skins*.

Hides include the skins of the larger animals, as those of cattle and horses. The parts of hides are known as *butts*, *backs*, *flanks*, etc., and form grades of thickness and quality.

Kips are the skins of small and yearling cattle, beyond the size of calf-skins.

Skins include those of calves, deer, pigs, sheep, seals, and some kinds of fur-bearing animals. The latter are usually called pelts or peltry, and of course preserve their hair.

Cattle-skins are the chief source of supply, and it is needless to cite the purposes to which they are applied. The former uses for armor, shields, and boats have decayed, but modern demands far more extensive have arisen. Calf leather is principally used for boot and shoe uppers and for bookbinding.

Sheep-skins are used for a commoner description of bookbinding, bellows, whips, aprons, bags, women's shoes, cushions, and seat-covers, carriage-tops, gloves, leggings, trunks, and many other purposes. Tanned in oil they form a substitute for real chamois leather.

Goat and *kid skins* form the best material for gloves, morocco leather, and ladies' shoes.

Deer and *antelope skins* are dressed in oil (see BUCKSKIN), and are used for gloves and other purposes. Their former use for breeches has become out of date. They afford material for making what now sells as *chamois* leather.

Horse-hides are used as a substitute for those of cattle in some cases, and probably unsuspected by those who buy articles made of this material. Split horse-leather is made up into shoes. Horse-hides are useful for making horse-collars.

Dog-skin is thin, tough, and valuable. It is good in gloves and for *whang*.

Seal-skin is much used as a fur, and, deprived of its hair, forms a good leather.

Hog-skin is yet to be found on saddles, for which it is better adapted than any other leather, being soft and pliable.

Porpoise-skins yield a soft, strong, durable leather, capable of a high finish.

Hippopotamus-hide makes a leather of great thickness, resembling a board when tanned. It is used in the construction of implements used for beetling in bleaching and washing cotton and linen goods.

Alligator-skins are now largely used.

Buffalo, *elephant*, *shark*, and *rhinoceros* skins also find their way to the tan-vat and a market.

1. *Morocco leather* is made from *goat* and *kid* skins, a peculiar grain being given to the surface.

2. *Chamois*, *shammy*, *shamoy*, or *shamois* leather was originally prepared from the skin of the *chamois*, but the skins of other goats, and even of sheep, are now dressed in the soft manner, and furnish skins for polishing, for gloves, and other purposes.

3. *Buff-leather* is so named from the *buffe* or wild bull of Poland and Hungary. It was used for armor, and tanned soft and white. It is yet used for cartridge-boxes and saber-belts in Europe.

4. *Whang* is tough leather made from skins of calves, dogs, ground-hogs, etc. It is used for bag-strings, whip-crackers, belt-lacing, and other occasional purposes.

5. *Russet* is leather finished except the coloring and polishing. In this condition tanned hides are stored, so as to be completed in any desired manner as the demand may suggest.

6. *Roan*; a leather made from sheep-skins in imitation of morocco, except the grain, and used for bookbinding.

7. *Skiver*; a thin split of leather used for hat-linings, etc.

8. *Wash-leather* is a soft-dressed skin suitable for polishing, for specie-bags, and for cleaning metals, plate, and highly polished articles.

9. *Tawed leather* is tanned with alum and salt, soaked in bran-water, dressed with flour of yolk of eggs, softened by rubbing and stretching.

10. *Fair leather* is finished in the natural color imparted by the bark, and not specifically colored.

11. *Russia-leather* is prepared by a careful and prolonged process, and is said to owe its peculiar smell to oil of birch.

12. *Shagreen* is an Oriental production, and resembles parchment. The hides of horses, asses, and camels are used. These are not tanned, but are indented by a covering of seeds and pressure. The dried skins are then sheared. They are then steeped to raise bulbs where the indentations existed.

13. *Enameled leather*. Leather split to the required thickness, and then subjected to two operations; one to make it impermeable to the varnish, and the other to coat it with varnish.

Digitized by Google

14. *Split leather.* Leather which has been split, the grain from the flesh side, in a machine for that purpose. It is sometimes done to lighten a leather, sometimes to make two thicknesses, both of which are utilized.

15. *Cordovan.* A Spanish leather supposed to be made of goat-skins, tanned and dressed, but often made of split horse-skins.

16. *Oil-leather* is curried in oil. Fish-oil, with or without potassa, is employed in alternation with drying. Fulling, graining, and pummeling are employed, followed by coloring, stretching, and surfacing.

17. *White-leather*, the same as *tawed leather.* The process leaves the leather *white*, differing thus from that tanned by ooze.

18. *Alum-leather.* The skins are tanned white by a solution of alum and salt. This process is adopted in making wash-leathers. See TAWING.

19. *Bazil.* Sheep-skins dyed with bark and used for making slippers.

20. *Jucten.* A name by which Russia leather is known. See RUSSIA LEATHER.

21. *Hungarian leather.* Made by a peculiar process, allied to *tawing.* See page 1142.

22. *Patent leather.* Made by a process of enameling.

23. *Saffian.* A kind of leather prepared in Asiatic Russia from goat skins.

24. *Maroquin leather.* Same as *saffian.*

Japanned, patent, varnished leather. See ENAMELED LEATHER, *supra.*

See the above under their alphabetical arrangement in the body of the work.

In connection with this subject it may be stated that sales of hides in the American market are made according to the following classification : —

Green hides are those which are sent in just as they come from the animal, never having been salted.

Part cured are those that have been salted, but not long enough to be thoroughly cured.

Green salted are those that have been salted and are thoroughly cured.

Dry flint is a thoroughly dry hide that has not been salted.

Dry salted is a thoroughly dry hide, having been salted while green.

In *green-salted* hides and skins, those weighing less than 8 pounds are called *deacons;* 8 to 14 pounds, *calf;* and 14 to 25 pounds, if plump, *kip,* but if thin and poor are called *runners* or *murrains,* and are sold at two thirds the price of good kip ; all above 25 pounds are called hides.

A green-salted hide is understood to be thoroughly cured, free from salt, dirt, meat, water, horns, tailbones, and sinews, and before being weighed all such substances are removed, or a proper reduction is made from the weight.

All stag, tainted, and badly scored, grubby, or murrain hides are called damaged, and go at two thirds price, unless they are badly damaged, when they are classed as *glue stock,* and sell at a much lower figure. A deduction of about 10 per cent is made on all branded hides. In dry hides there are other kinds of damaged, such as moth-eaten, sunburned, or weather-beaten.

For varieties of leather and leather-working tools, see under the list in the next column, *et seq.*

Leather is formed by the combination of the substance of the skin with any other compound which has the property of rendering it imputrescible and elastic. — MUSPRATT.

Tannin is the substance generally employed, and has the effect of solidifying the gelatino-fibrous membranes, so that they are no longer putrescible under the joint influence of warmth, air, and moisture.

The *copperas* process, which impregnates the fiber with an insoluble sub-sulphate of peroxide of iron, is effective in the same way.

The *alum process* is one in which the alumina combines with the tissue. See TAWING.

The supposed reaction is the decomposition of the alum by the salt, producing sub-chloride of aluminium, which unites with the fiber. See TANNING.

Tanned skins are *curried* by soaking, rubbing, and paring (see CURRYING), smeared with *dubbing,* which penetrates the leather as the moisture evaporates ; *waxed,* by rubbing on the flesh side with oil and lampblack ; *black*-sized with a brush or sponge ; *tallowed ; slicked* on the flesh-side with a glass-*slicker.*

Leather curried on the *hair* or *grain* side, termed *black on the grain,* is blackened with *iron-liquor* and rubbed with an iron slicker before applying the grease.

The *grain* is raised by a *pommel* or *graining-board.*

The varieties of leather commercially considered are, —

Leath'er, Ar-ti-fi'cial. Cloth treated with oils, pigments, and gums, to give it a shining, water-proof surface.

The materials used are :—

Linseed and resin oil.

Glue, glycerine, boiled linseed-oil, caoutchouc, coloring matter ; impressed with a design while hot, to imitate morocco, afterwards treated with a solution of chrome alum or copperas.

Turpentine and naphtha.

Lampblack.

Caoutchouc and gutta-percha.

Stearine, gelatine, leather parings.

Bark infusions, alum.

In various combinations and proportions.

Gunby's artificial leather, 1824 (English), cotton, linen, woolen, or felt cloth is coated with the following composition :—

Common glue-size, 8 parts ; boiled linseed-oil, 4 parts ; lampblack, 1 part ; white-lead, 2 parts ; pipe-clay, 2 parts.

This is to be melted and well mixed. The cloth is stretched and the composition spread by a palette-knife. Dry by a stove ; repeat the composition and dry. Four or five coats may be thus applied. Varnish to give a gloss.

Hancock's artificial leather (English). A card or wide sliver of flax or cotton fibers is condensed so as to resemble a felted material. This is treated with liquid caoutchouc laid on by a spatula. It is then rolled, coated with resin, and rerolled.

Bonneville's artificial leather is made from leather cuttings, shavings, and parings, by reducing while in a dry state to powder. This powder is next mixed with a solution of india-rubber, with or without a solution of gum-lac, or of marine glue, to a suitable consistence. When partially dried, which process is effected by straining on wire-cloth or perforated metal, the sheets or slabs of artificial leather are pressed between rollers, and, if required, are ornamented in any suitable way.

In general terms, artificial leather may be stated

Digitized by Google

to be any kind of cloth or paper immersed in a solution of the following ingredients, or any of them in combination : Gelatine, glue, soap, oil, glycerine, saccharine matter, water, clay, aluminous earth, plaster, ground slate or stone, cement, any oxide of metal, or pigment.

Or any kind of fabric or paper in a composition embracing any of the gums or resins, — dextrine, caseine, albumen, gluten, or starch.

The following ingredients are also used : tannic-acid, cutchin, gallic acid, boracic acid, alum, borax, chrome alum. See also LEATHER-PAPER.

Leath'er-awl. 1. A shoemaker's piercing-tool for stitching or lasting. See AWL.

2. A tool for lacing belts. In one case it has a broad point, which fades away into two cutting edges on a conical scoop-shaped blade, which make a clean, circular cut of the desired size within the capacity of the blade.

Or it has an eye-point to carry the lacing through.

Leath'er-board. (*Leather.*) A composition of leather scraps and paper material, ground together and rolled out into sheets.

Leath'er-board'ing Ma-chine'. A machine in which tanned leather may be pressed and rubbed to supple and soften it, so as to fit it for the subsequent operations, which are generally comprised under the term *finishing*. See BOARDING-MACHINE, Figs. 740, 741.

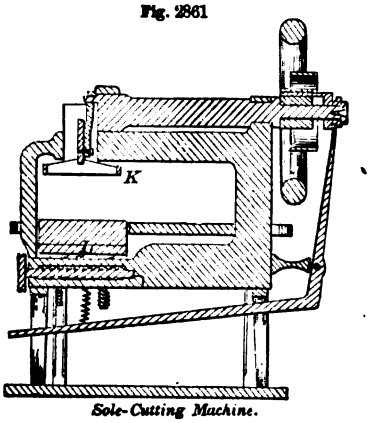
Leath'er-buff'ing Ma-chine'. A machine in which the surface of leather is reduced to a smooth but not polished surface, the face being left with a slight nap, velvety, like buff leather.

Leath'er-cham'fer-ing Ma-chine'. A machine for beveling the edges of straps or strips of leather, giving a feather or thinned edge thereto. It is a skiving process, and is usually performed on a *skiving* or *shaving* machine.

Leath'er-cloth. (*Fabric.*) A fabric covered with a water-proof composition, usually having a polished surface. It generally consists of a paint or a varnish, sometimes the former with a covering coat of the latter. The changes in menstruums, resins, pigments, and coarse and cheap materials, which are added for quantity, are so various that room cannot be afforded for stating them at length. See ENAMELED CLOTH ; LEATHER, ARTIFICIAL.

Leath'er-cor'ru-gat'ing Ma-chine'. A machine in which leather is crimped, corrugated, or fluted for certain purposes in manufactures. It is usually done by passing between a fluted and a plain roller and drying while the indentations are preserved ; or it may be done by passing the leather while damp between plates or dies of the requisite form.

Fig. 2861



Sole-Cutting Machine.

Leath'er-creas'ing Ma-chine'. A machine for ornamenting the edges of leather straps by passing between rollers indented with the required patterns in intaglio and cameo.

Leath'er-cut'ting Ma-chine'. A machine for cutting leather into shapes for shoe-stock or other purposes ; sole-leather into soles and lifts, for instance. The sole-leather is placed on the adjustable table *L* beneath the platen *K*, and a die which is of the shape of the piece to be cut is placed upon the leather. Pressure on the treadle throws the friction-clutch into operation, and the cam-shaft is rotated, depressing the platen upon the die and cutting a sole from the leather.

Leath'er-dio'ing. Another name for *leather dressing* or *finishing* or *polishing*. Also known as *glassing*, the tool for the purpose being usually a slip of glass set in the grooved edge of a wooden strip which forms the handle.

Leath'er-dress'ing Ma-chine'. A machine in which tanned and curried leather undergoes the finishing operations which improve its texture and surface. The term is somewhat indefinite, as *boarding* or *graining*, *scouring*, *coloring*, and *glassing* or *polishing* are or may be all performed upon the leather in course. See under those heads.

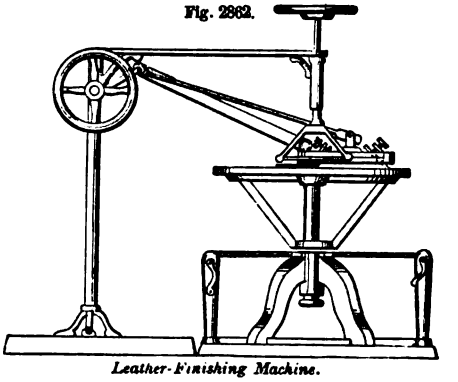
Leath'er-em-boss'ing Ma-chine'. A press or roller having an engraved pattern or one otherwise procured by casting or electro-plating, and which is impressed upon leather in a damp state. Schroth's English patent, 1839, describes dies of type-metal or a fusible alloy containing bismuth ; the leather is beaten soft in water, wrung, pressed, rolled, and fulled, until it becomes quite supple. It is then laid on the die and driven in by a bone tool or by a press. It is allowed to dry *in situ*. See also LEATHER-PEBBLING MACHINE.

Leath'er Feath'er-edg'ing Ma-chine'. One for skiving off the edge of a piece or strip of leather, gradually thinning it toward the edge, which is left comparatively sharp. See LEATHER-SKIVING MACHINE.

Leath'er-fin'ish-ing Ma-chine'. A machine in which tanned and curried leather is dressed to give it the required texture and surface finish.

In the example, the leather is placed on the table, which has horizontal and rotary movement

Fig. 2862.



Leather-Finishing Machine.

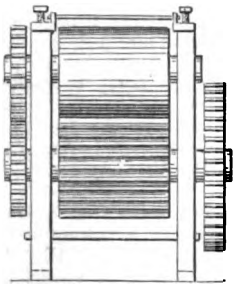
beneath the reciprocating "plane stock," which carries two slickers and a circular knife, which act upon the surface of the leather. The term is somewhat indefinite, and may include boarding, graining, glassing, polishing, etc.

Digitized by Google

Leath'er-flesh'ing Ma-chine'. A machine for reducing the thickness of leather by shaving off a portion of the flesh side.

Leath'er-flut'ing Ma-chine'. A machine for corrugating leather, as in the example, in which the leather when damp is run between a fluted and a plain roller, and afterward dried between heated plates of similar conformation. Sole-leather so prepared is used for work of a cellular character.

Fig. 2863.



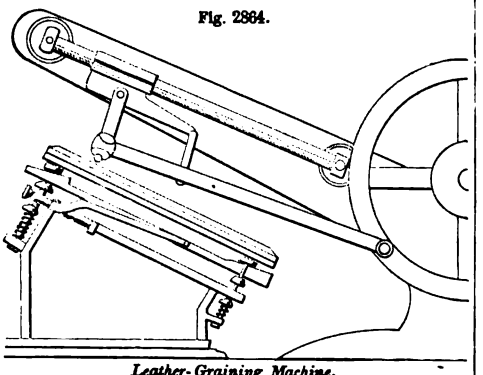
Fluting-Machine.

Leath'er-glass'ing Ma-chine'. One in which the leather is dressed or polished in a machine which has a "glassing-tool" attached to a suspended arm, which is vibrated by crank and pitman over the leather, which rests on a yielding bed below, curved to the arc of the swinging tool. The glassing-tool has an elastic bearing at its pivot to enable it to yield to inequalities. See LEATHER-POLISHING MACHINE.

Leath'er-glu'ing Ma-chine'. A machine for holding firmly together the scarfed ends of united sections of leather belting. See GLUING-PRESS, in which the contiguous, beveled, cemented ends of the leather strips are clamped between the bed-piece and the face of the pivoted platen.

In Fig. 2864, the leather is laid upon an inclined table, vertically adjustable by inclines and supported by springs which give a certain elasticity to the bed.

Fig. 2864.



Leather-Graining Machine.

The graining-tool is reciprocated above the leather, a crank acting upon a pitman and arm, the latter depending from the sliding carriage.

Leath'er-gouge. (*Saddlery.*) A tool used to cut channels in leather for receiving the thread of a line of stitches.

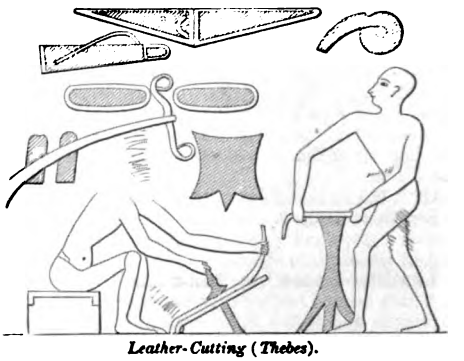
Leath'er-grain'ing Ma-chine'. A machine in which tanned hides may be boarded, grained, or softened, to render them flexible, that they may be in the supple and absorbent condition fit for the other finishing processes. See BOARDING-MACHINE, Figs. 740, 741, *ante*.

Leath'er-grind'er. A machine for reducing scraps of leather to shreds, in order that the material may be made into washers, in-soles, and heels for shoes. The machine has a feeding-box, a follower or piston, by which the shreds are kept in a compact mass while being acted upon by a set of revolving tearing teeth. A set of revolving clearers act to clear out the tearing teeth, and a contrivance is used for throwing streams of water upon the teeth.

Leath'er-ham'mer-ing Ma-chine'. A machine of the nature of a drop-hammer or *oliver*, for compacting leather for shoe-soles.

Leath'er-knife. The leather-cutter's knife with a curved blade seems to have undergone no special

Fig 2865.



Leather-Cutting (Thebes).

change for three thousand years. The figure in the accompanying cut is from a group on a building at Thebes; it represents men cutting out harness.

Leath'er-pa'per. A mode of preparing paper, in which it is made to assume the appearance of leather. The Japanese process is about as follows: Sheets are damped and laid in pairs between sheets of varnished paper, which have a crinkled grain running in one direction. They are then wound upon a roller, the grain of the pattern of the paper derived from the crinkled sheets between which it was laid running around the roller. The roller being slipped out, the roll of paper is slipped into a cylinder and subjected to endwise pressure, reducing it to three quarters its original length. It is then unwrapped and pressed to remove the deep marks. It is then again rolled, colored, oiled, varnished, pressed, and dried. By means of parallel or cross lines on the rollers, the upper surface of the paper is made to resemble leather exactly in all its varieties. The paper being pressed to one third, or even to one half, its original thickness, and the passage through the rollers giving it a fine-grained appearance, makes it valuable to picture-printers, as the surface has the appearance of crêpe silk.

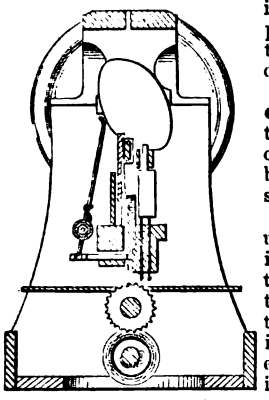
There is another variety of leather-paper which is smooth and transparent, resembling hog-skin very much. This is manufactured by a process of hammering, and is the higher priced.

Leath'er-peb'bling Ma-chine'. One in which a fancy surface is given to dressed leather, resembling morocco, levant, hog-skin, or other fancy style. The leather is passed upon a bed beneath a roller having the desired pattern. The pattern is given by soft metal, which has been cast upon an original surface of the required character (see LEATHER-EMBOSSING), or the pattern of the roller is obtained by taking an electrotype copy of some selected piece of leather and transferring to the roller.

Leath'er-piero'ing Ma-chine'. A machine for stabbing objects of leather, as, for instance, straps or soles for stitching. In the example, the leather is fed first to the piercing-tool, and then to the die which forces the wire into the openings, the two operations being performed simultaneously in consecutive openings. The wire is fed by a cam

Digitized by Google

Fig 2866.



Leather-Piercing Machine.

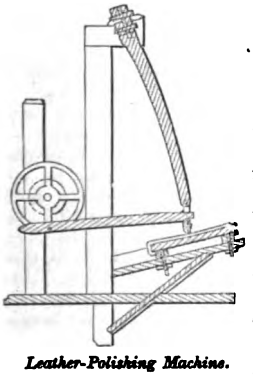
acting on feed-wheels, is cut by a chisel, and placed in proper position for the driving-die.

Leath'er-pol'ish-er. A machine in which the surface of leather is condensed and polished beneath a reciprocating slicking-tool.

The leather is placed upon a table whose top is curved to agree with the arc of oscillation of the tool. The glassing-tool has an elastic bearing at its pivot, which enables it to yield to inequalities, and it is reciprocated by connection to a wrist on a hand-wheel.

Leath'er-press'ing Ma-chine'. A machine in which leather previously damped, and in some cases after receiving a preliminary local stretching, is pressed into form between corrugated or salient and receding surfaces, as the case may warrant. Used for making harness-pads and many other purposes.

Fig. 2867.



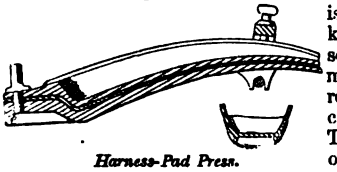
Leather-Polishing Machine.

In the example, the pad-holder consists of a thin shell of cast-iron, having on its bottom two ribs to form a support for the holder when clamped on the stitching-horse.

Leath'er-punch. A hand-tool for making holes in leather for the insertion of eyelets or lacing.

Fig. 2869 has a lock-plate pivoted by its shank within the jaw of the punch, and is operated by a key-like handle, so that it may be made to hold and release different cutting-tools. The folded end of the strap is operated upon by the cutter, and an oblong opening is formed thereby.

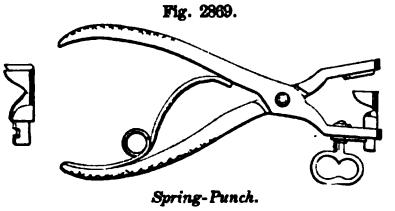
Fig. 2868.



Harness-Pad Press.

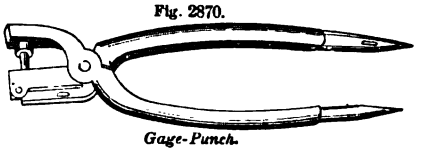
Fig. 2870 is a belt-punch, in which the jaws and punching-devices are combined with a knife-blade, a punch, a needle, and an awl, arranged with reference to each other upon the respective portions.

Fig. 2869.



Spring-Punch.

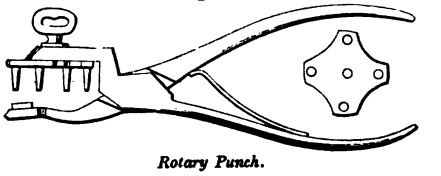
Fig. 2870.



Gage-Punch.

Fig. 2871 is a spring-punch, having a series of tubular cutters which differ in size, and either of which may be readily brought into requisition.

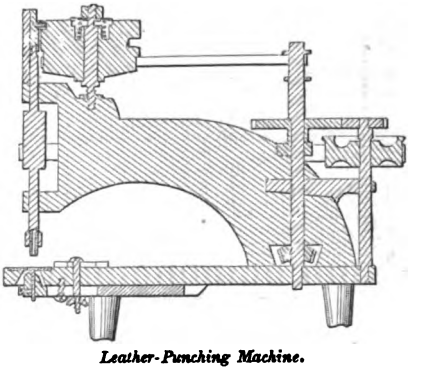
Fig. 2871.



Rotary Punch.

Leath'er-punch'ing Ma-chine'. A machine in which punch and die are automatically operated, while the material is fed between them by hand or otherwise. The punch has an annular sleeve-die which makes a circular imprint around the opening, a pin beneath forcing the pellet into the throat of the die. The punch and die-stock are reciprocated by a wrist and cam-wheel, a certain elasticity of the latter on its shaft providing for the requirements of

Fig. 2872.



Leather-Punching Machine.

varying thicknesses of leather. The punch is revolved by band and wheel.

Leath'er-quilt'ing Ma-chine'. A form of sewing-machine.

Leath'er-rais'ing Ma-chine'. (*Harness.*) A machine for giving raised and ornamented or beaded edges to straps. A *leather-creasing machine.*

Leath'er-re-duc'ing Ma-chine'. A machine to shave or reduce the inequalities of the flesh side and bring the piece of leather to a uniform thickness.

In the example, the machine has pairs of receiving and delivering rolls, and between them a flat reciprocating knife, which is set obliquely across the path of the leather and thus delivers a draw-cut.

Leath'er-roll'ing Ma-chine'. A machine to compress and harden leather, instead of hammering it. The journals of the lower or pressure roller are mounted in a movable lever frame, which is provided on the under side of either end with projec-

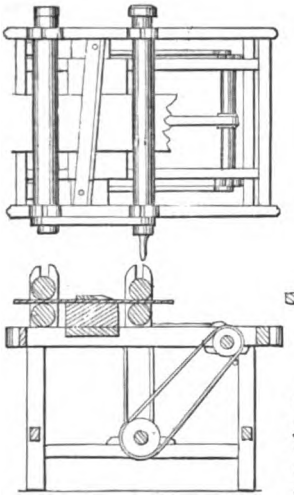
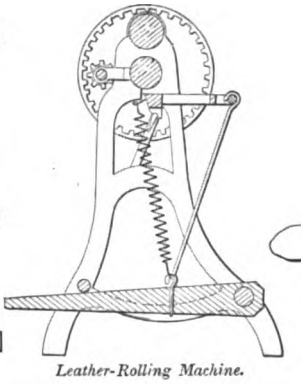
Fig. 2873.



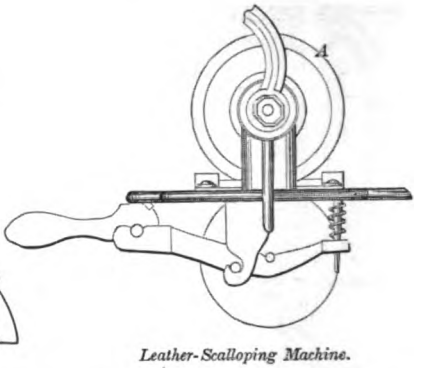
Leather-Reducing Machine.

Fig. 2874.



Leather-Rolling Machine.

Fig. 2877.

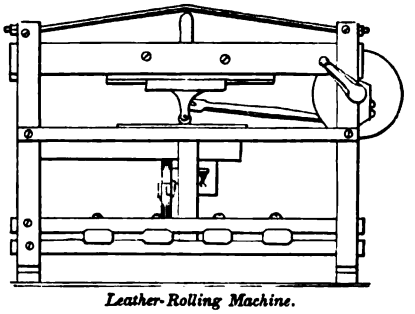


Leather-Scalloping Machine.

tions resting upon joints, which are supported upon the central portion of a cross-piece in the main frame, in such manner as to operate with the lever frame like a toggle-joint, in addition to the usual compound lever employed for moving the pressure-roller.

In another machine, the skin of leather is placed on the table, which is raised more or less by toggle-levers, to regulate the pressure of the roller. The

Fig. 2875.

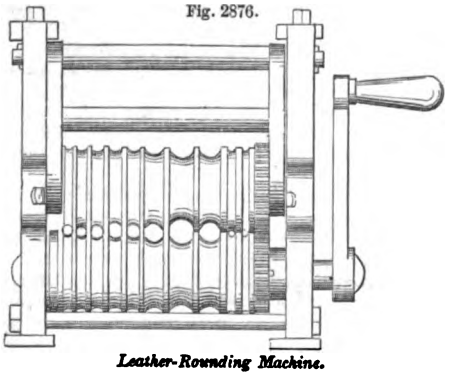


Leather-Rolling Machine.

roller is journaled to a slide reciprocated by connection to a crank. The tool is a steel roller or glass edge.

Leath'er-round'ing Ma-chine'. (*Harness-making.*) A machine for making round lines or whip-covers from flat strips of leather, by gradually turning the edges inward and strongly compressing the material. In the example, the rolls have graduated circular apertures between them, and the upper one is carried in a frame pivoted so as to be adjustable in distance from the other roller. The action is somewhat similar to that of rolling gun-barrels from skelps.

Fig. 2876.

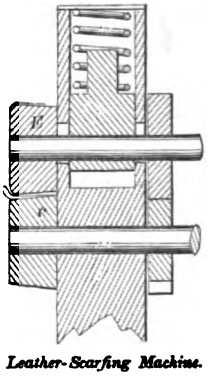


Leather-Rounding Machine.

Leath'er-scal'lop-ing Ma-chine'. A machine for giving a wavy outline to the edges of leather straps to be used in making ornamental harness, and for other purposes. The example has a pair of wavy-edged disks set at any required distance apart, according to the width of strap operated upon. In the drawing, the scalloped shape of the disk *A* is not apparent, and the farther disk is hidden by the near one. The pressure of the bed-roller against the scalloped disks is increased by a cam-lever at one end of the supporting lever of the bed-roller. Motion is given to the scalloped disks by a winch.

Leath'er-scarf'ing Ma-chine'. One for beveling the edges of leather, slanting off the thickness to enable pieces to be united by a scarf-joint. In the example, the stationary horizontal cutter, opposed to the space between the rollers *E c*, cuts the leather obliquely as it passes through between them.

Fig. 2878.



Leather-Scarfing Machine.

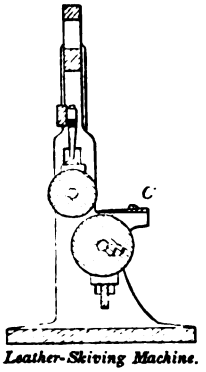
Scarfing, skiving, chamfering, and *feather-edging* are synonymous terms; the first two more often applied to leather generally, and the last to *beveling* leather for soles, leaving a blunt edge. The lap-seam uniting the vamp and quarters, in fine work, is sometimes formed with skived edges to avoid a ridge. In coarse work, as plow-shoes, the leather about the ankle-opening is chamfered from the inside to prevent chafing. Leather is also skived for making lap-joints in round work and belting.

Leath'er-scour'ing Ma-chine'. A form of leather-finishing machine, or rather one of the modes of operation of such a machine, which is usually adapted for *scouring, graining,* or *boarding* or *polishing,* according to the character of the tool which is brought upon the skin under treatment. See LEATHER-FINISHING MACHINE.

Digitized by Google

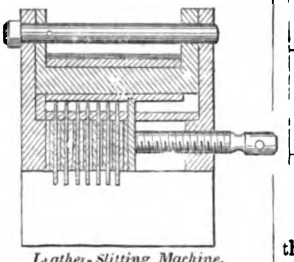
Leath'er-skiv'ing Ma-chine'. A machine for shaving leather to a thickness, skiving off a portion of the flesh side. In the illustration, the leather is passed obliquely upward between the rollers and against the edge of the knife *C*, whose

Fig. 2879



Leather-Skiving Machine.

Fig. 2880.



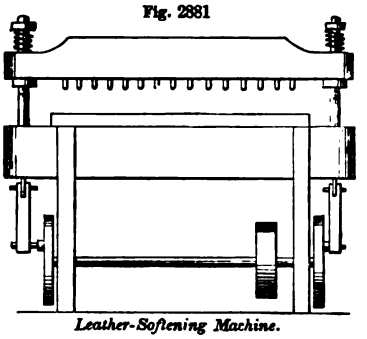
Leather-Slitting Machine.

position relatively to the adjustable roller *D* determines the thickness of the leather which passes between the knife and roller, the skive passing above the knife.

Leath'er-slit'ting Ma-chine'. A machine used principally by harness-makers and saddlers, for cutting leather into straps; the knives are adjustable in distance from each other, to fit them to form straps of different widths. In the example, a series of knives is placed between guides separated by plates and clamped by a set-screw. A segmental, leather-covered frame is hung so as to be brought down over the cutters or thrown up therefrom. The leather, after reduction to the proper thickness, is placed on the cutters and the block brought down thereon. The leather is then drawn through between the gang of cutters and the segmental plate above, which form a surface against which the knives cut.

Leath'er-soft'en-er. A machine for working dry hides or leather, to make them flexible, and enable them to be worked without breaking. It is a preliminary to the operations of tanning dry hides or of finishing processes with tanned skins. The machine has corrugated rollers which press and extend the leather, or it acts by pounding. In the

Fig. 2881

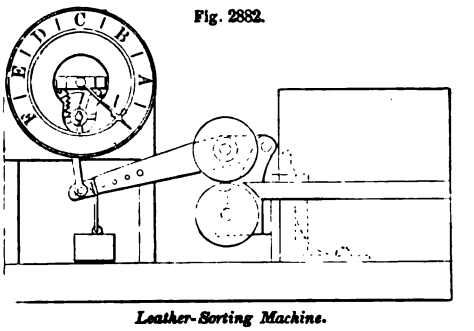


Leather-Softening Machine.

example, the bed has a series of depressions, and the cross-head a series of matching projections, between which the leather is passed. The cross-head has vertical reciprocation from two cranks on a rotating shaft beneath.

Leath'er-sort'ing Ma-chine'. A machine in which leather strips are assorted according to thickness. In the example, the strips of leather cut from the skin to form shoe-binding are thus sorted. Connected with the contacting surfaces, between which

Fig. 2882.



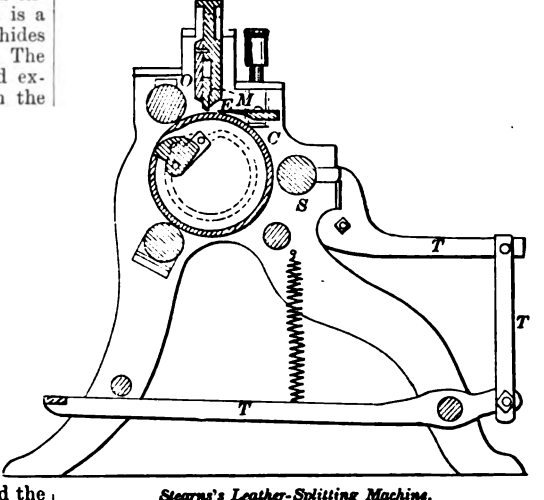
Leather-Sorting Machine.

the strips pass, is mechanism indicating by a finger and dial the thickness of the passing strip.

Leath'er-split'ting Ma-chine'. An apparatus for dividing leather into two or more layers. Split leather is much used in making boots and shoes of cheap quality. The advantage in using the splitting-machine is that the quantity of leather surface is doubled. By splitting so as to preserve the *grain side*, one sheet of very fair leather may be obtained, while the other (*skiving*) is fit for trunk-covers, etc. The machine consists essentially of one or more rollers, which draw the leather against the edge of a horizontally arranged long knife, by which it is divided, one half passing above and the other below the knife.

In Stearns's machine (Fig. 2883), the leather is drawn forward by the tooth *e* on the carrying cylinder *C*, passes between the roller *O* and presser-bar *E*, and after being split by the adjustable knife *M* is drawn between the carrying cylinder and the roller *S*, in order to compress and smooth it; the amount of pressure being governed by the treadle and levers *T T T*.

Fig. 2883.

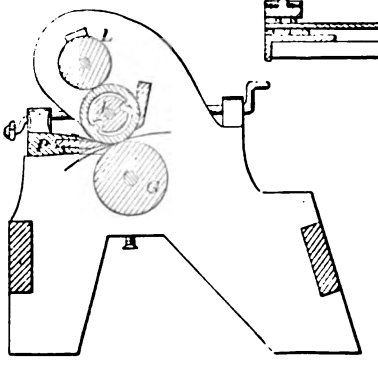


Stearns's Leather-Splitting Machine.

In Marden's machine (Fig. 2884), the leather is drawn to the knife *P* between the rollers *G J*, the latter gears loosely with both the rolls *G L*, and its bearings are elongated vertically, that it may rise and fall to admit leather of varying thickness.

Digitized by Google

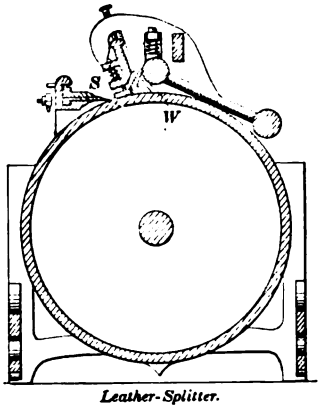
Fig. 2884.



Marden's Leather-Splitter.

Fig. 2885, the knife *S* reciprocates longitudinally, the cylinder is adjustable, and the leather is held down by a foot on the presser-bar *W*.

Fig. 2885

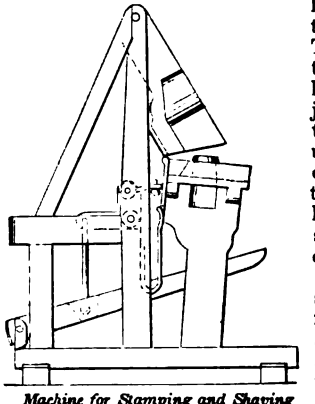


Leather-Splitter.

In another machine, the leather is split by an endless, knife-edged, steel band, sharpened by an emery-wheel while running.

Leath'er-stamp. A machine for stamping and shaping leather. The die and follower are jointed to form a toggle. The lever operates the bell-crank lever and toggle-joint, and brings the follower down upon the knife or die-plate, and thereby cuts the leather to the shape of the face of the die.

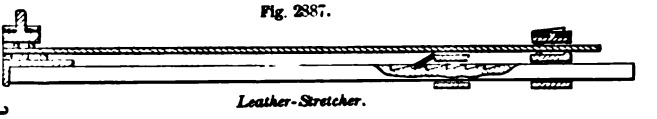
Fig. 2886.



Machine for Stamping and Shaving Leather.

Leath'er-stretch'er. A frame in which a side of leather is stretched, that it may dry flat. Some frames have tenter-hooks, others are made with sides expanded by wedges, like a painter's canvas. In the example, the bar has one fixed and one movable clamp, and between them is a slide-bar having a pawl to catch in a ratchet in the main bar, and rubber springs acting on the movable clamp.

Fig. 2887.



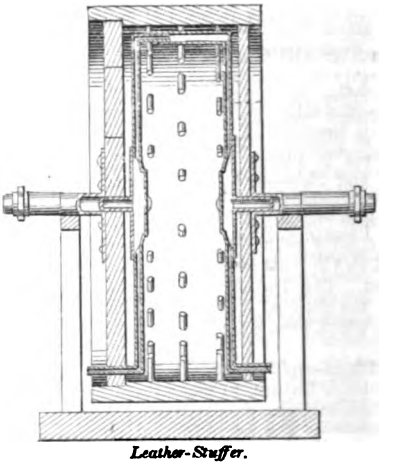
Leather-Stretcher.

Leath'er-strip'ing. (*Shoemaking.*) A machine for marking binding-leather with stripes to be cut into strips for shoe-binding, etc.

Leath'er-strip'ping Ma-chine'. A machine for cutting sides of leather into strips of uniform width, from which soles and heels are afterwards to be punched by hand or by power.

Leath'er-stuff'er. A machine or a revolving chamber in which hides are made supple and stuffed with dubbing, to make them soft and pliable. It is the equivalent of the breaking-machine, which is used to break dried hides before tanning. The hand-process is to rub and bend them gently until the fibers yield and gradually absorb moisture. In the stuffer shown in the figure, the heating-chambers of the cylinder are placed inside the heads, and receive steam through the tubular gudgeons. The steam passes off through radial pipes. The hides tumble about in the box, become softened by heat and impact, and absorb the dubbing, which is tallow mixed with fish-oil or petroleum.

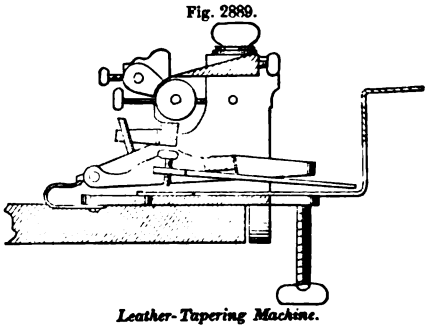
Fig. 2888.



Leather-Stuffer.

Leath'er-ta'per-ing Ma-chine'. A machine

Fig. 2889.



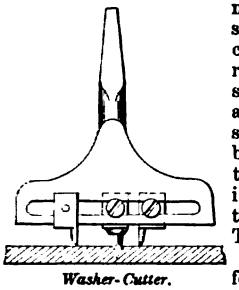
Leather-Tapering Machine.

Digitized by Google

in which leather straps may be shaved or beveled toward the end. Such a machine is arranged so as to be adapted to any width or thickness of leather. In the example, the cutter is hinged at one end to a stationary frame, and is vertically adjustable at the other end. The axis of the friction-roller connected with the vertically adjustable frame is directly under the cutting-edge of the knife. The roller is supported on a sliding frame that is gradually raised toward the knife, for tapering the ends of leather belts.

Leath'er-wash'er. Tools for cutting leather-washers are on the principle of the trepan or the annular auger. The example shows one in which the cutters are both adjustable relatively to the center-pin, so as to cut a washer of any size with a hole of any size. The washers are cut by revolving or turning the tool upon the center-pin, in the material from which the washer is to be made. The tool is held in a brace.

Fig. 2890.



Washer-Cutter.

Leav'en. Sour dough, for producing fermentation in a quantity of freshly made dough. A substitute for *yeast*. See BREAD.

Le-clanche' Bat'ter-y. A form of galvanic battery invented by Georges Lionel Leclanche, a French electrician.

Two forms of battery are known by this name: —

1. A porous cup in which the carbon or − element is placed, the remaining space in the cup being filled with a mixture of peroxide of manganese, chlorohydrate of ammonia, and sawdust. This cup is placed in a cell in which the zinc or + element is also placed. One liquid is used containing a salt which has no chemical action on the peroxide of manganese, but which is capable, by its electrolytical decomposition, of rendering soluble the oxides of manganese. The salt commonly used in the exciting liquid is muriate of ammonia. The battery-cup is hermetically sealed for convenience of transportation. Patented August 23, 1867. Reissued February 17, 1874.

2. A plate of copper with wire attached is covered in the jar with powdered carbonate of copper; over this is placed a stratum of sand, in which is imbedded the zinc with wire attached. The whole is then saturated with a solution of chlorohydrate of ammonia. June 5, 1866. Reissued February 17, 1874.

Lec'tern. (*Architecture.*) The reader's desk in a church.

Ledge. 1. (*Architecture.*) A small molding, as the Doric drop-ledge.

2. (*Joinery.*) *a.* A piece against which something rests; as the batten on the back of a door, the fillet against which a door closes, etc.

b. A shelf.

3. (*Mining.*) A stratum of metal-bearing rock.

4. (*Shipbuilding.*) A thwart-ship piece in the deck-framing. See SHELF-PIECE.

A support for the decks, parallel to and intermediate between the beams. See HEAD-LEDGE.

5. (*Printing.*) A piece of furniture; a stick used in wedging up.

Ledg'er. 1. (*Scaffolding.*) A horizontal pole, parallel to the walls, lashed to the *standards* or vertical poles, and supporting the *putlogs* on which the boards of the bricklayers' scaffold rest.

2. (*Masonry.*) A large, flat cap-stone, over a tomb for instance.

Ledg'er-blade. The stationary blade with a rectilinear edge, placed as a tangent to the spirally bladed cylinder, by which cloth is shorn and the nap reduced to a length.

Another form of cloth-shearing machine has a semicircular ledger-blade, and a large revolving-wheel containing 8 small cutting-disks, revolved by planetary pinions, and acting as shears in connection with the edge of the ledger-blade. See CLOTH-SHEARING MACHINE.

Ledg'ment. A string-course, or horizontal suite of moldings, such as the base-moldings of a building.

Lee. (*Nautical.*) The side of a ship opposite to that from which the wind blows; the sheltered side. The *lee-way* of a vessel is the amount of its drifting to *leeward*.

Lee-board. (*Nautical.*) A board lowered on the lee side of a flat-bottomed vessel to act as a temporary keel in avoiding lee-way, preventing the vessel drifting to leeward.

A *center-board* is a lee-board, raised and lowered in a water-tight well amidships. See CENTER-BOARD; SLIDING-KEEL.

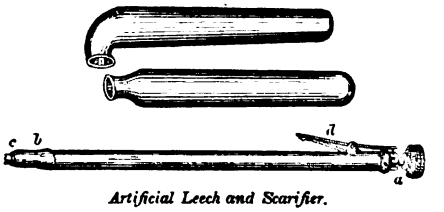
Leech. (*Nautical.*) The side edge of a square sail. The foremost edge (for the time being) is the *luff* or *weather-leech*.

In a *fore-and-aft* sail, the after edge is the *leech*.

Leech, Ar-ti-fi'cial. (*Surgical.*) A light glass tube from which the air is expelled by the vapor of ether, and whose mouth is then applied to a previously scarified portion of the body.

To expel the air from a tube, a few drops of ether are poured into it, and it is then immersed as far as the mouth in hot water until the ether boils briskly. The mouth of the tube is then applied to the skin,

Fig 2891.



Artificial Leech and Scarifier.

and held for an instant, when it will be found to be firmly attached, and can be left to itself. Each tube will draw about two ounces of blood. For uterine practice they are made long enough to be applied through a speculum.

The scarifier is simply a tube one eighth inch in diameter, having a cutting-edge at one extremity. By a simple device this is made to rotate rapidly, making, when applied to the skin, a circular incision, the depth of which is regulated by a gage.

In the cut, *a* represents the buttons by turning which the instrument is wound up, *d* the trigger by which the spring is released, *c* the cutting-edge, and *b* the gage for regulating the depth of the incision.

Themison, a physician of Laodicea who flourished a little before Celsus (first century A. D.), mentions the use of leeches.

Michael Servetus, burnt at Geneva in 1553, announced and explained the circulation of the blood, correctly describing the action of the heart, the duty of the arteries and the veins, and the influence of the lungs. He correctly describes the single circulation, and is the first to employ the term of *anastomosis* to express the communication between the veins and arteries in the tissues. See Servetus, "De Christianissimi Restitutione." See LANCET.

Digitized by Google

Leech-line. (*Nautical.*) A line attached to the leech-rope on the edge of a sail, and passing up through a block on the yard, to haul on the leech; as the *bunt* and *leech lines*, the *preventer leech-line*.

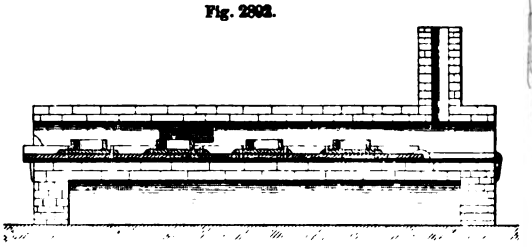
Leech-rope. (*Nautical.*) That part of a bolt-rope along the vertical edge of a sail. The *leeches* are hauled by *leech-lines*, which pass up through blocks on the yards, and *braid* up the sail.

Lee'fange. (*Nautical.*) An iron across a deck or on the taffrail, for the sheet of a fore-and-aft sail to slip on in tacking.

Leer. The annealing chamber or arch of a glass manufactory. *Lier.*

It is sometimes a simple oven, or it may be a long chamber through which the ware is pushed in trays, the period of passage being sufficient for the annealing operation. In the example, the heat is received

Fig. 2892.



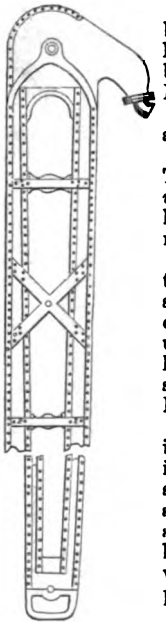
Leer.

at an opening between the points of reception and discharge, and is graduated toward both ends.

Left-hand Rope. Rope laid up and twisted "against the sun," as it is termed. *Water-laid* rope.

Left-hand'ed Screw. A screw whose threads advance "against the sun," that is, from right to left. This is the opposite to the common, or *right-handed* screw, which is operated by turning it in the direction of the hands of a watch.

Fig. 2893.



Elevator-Leg.

Leg. 1. (*Elevator.*) The movable dependent case containing the lower end of the belt of iron buckets of a grain-elevator. See ELEVATOR.

2. (*Furniture.*) A support of a table, chair, stove, etc.

3. One limb of a compass. The legs are called *pencil*, *pen*, *wheel*, *extension*, *reversible*, *point* legs, etc., according to their furnishing or adaptation.

Leg, Ar-ti-fi'cial. A prosthetic lower limb, which is made specially for amputations above or below the knee. The form is usually in imitation of the natural leg, but sometimes it is made skeleton-wise for lightness, as in Fig. 2894.

Among the materials used for its structure are raw-hide, which is very light and stiff for its strength; splints crossing at right angles and glued together; bands and strips of wood interlaced; hollow shell of wood; basket-work of wire; vulcanite; gutta-percha.

"The cripple may go out on the Sabbath with his wooden leg: such is the dictum of Rabbi Meir; but Rabbi José prohibits it." — MISHNA.

The compass-joint for the knee, and the ball-and-socket joint for the ankle, are described in Pott's English patent, 1801.

Fig. 2894 is an artificial leg adapted for leg amputation at the upper third, where the knee rests in a

Fig. 2894.

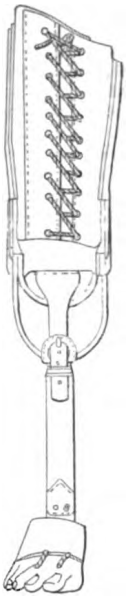


Fig. 2895.

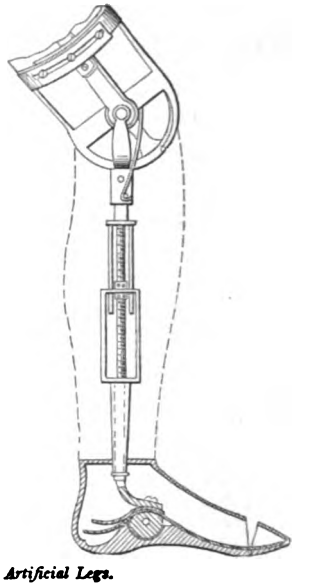
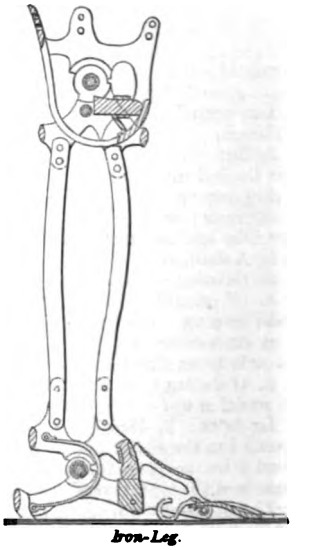


Artificial Legs.

cushioned socket, or it may answer for the less common amputation at the knee-joint, the axis of movement being above the knee-rest and in prolongation of the axis of motion of the knee. *b b* are branches of the thigh-straps; depending from the knee-joint are branches which connect with and brace the tibia post.

Fig. 2895 is a leg adapted for thigh amputations. The bar of the leg is adjustable in length, and is planted upon a segment of a cylinder, which has a backward and forward oscillation in its socket; the toe and heel leaf-springs modify and limit its vibrations. The toe-spring extends the toe-section, which is hinged to the front part of the foot, and flexed by the act of walking. The slotted hoops and set-screws of the thigh adjust its capacity. An axial coil on the knee-articulation extends the leg for forward movement when raised from the ground.

Fig. 2896.



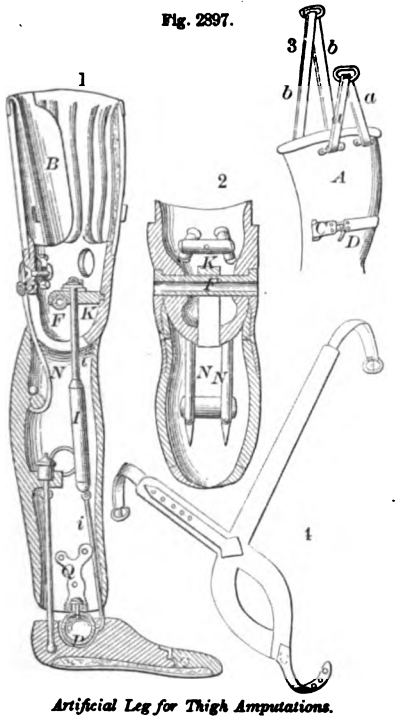
Iron-Leg.

Digitized by Google

In Fig. 2896, the frame is made of malleable cast-iron, with projections to correspond with the natural processes. Straps unite the anterior and posterior portions of the knee-frame and keep the covering in place. The toes are of spring metal, and attached separately to the foot; a spring at the ankle articulation depresses the heel.

Fig. 2897 is an artificial leg for thigh amputations. The socket *A* has a pad *B* and strap *D* for adjusting the size to the stump. *K*, in 1 and 2, is a bridge-piece in the upper section, resting on the knee-bolt *F*, and affording the superior point of attachment for the extensor-spring *I* and tendons *i i*, which throw the foot upward and forward as soon as it is lifted from the ground in walking. The ham-

Fig. 2897.



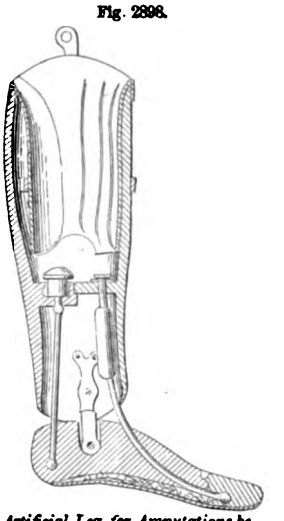
Artificial Leg for Thigh Amputations.

strings *N N* are attached to the posterior portions of the thigh and leg, to act as checks to the forward motion of the leg.

The ankle-joint consists of a socket in the foot, and a ball *P* attached by its neck and the iron frame *Q* to the leg, and has a horizontal stud upon it, fitting its appropriate recess in the socket in the foot, so as to prevent vibration in a horizontal plane, while leaving the joint free for motion in vertical planes, as described. The elastic straps *a b* (3) are proportioned as to length and strength, and afford a means of attaching the suspensory yoke (4), whose straps pass over the shoulders, so as not alone to bring the weight upon the framework of the body, but also to enable the shoulders, by their motion, to influence the action of the artificial limb. See patents of Bly, Condell, and others.

Fig. 2898 is an artificial limb intended for amputations below the knee, and is supported by straps secured to the sides of the socket, and an elastic band secured to the front of the socket, the said straps and band uniting in a stronger elastic strap which passes upward, and is suspended from a yoke-strap over the shoulder. The foot-piece has a socketed axial-bolt passing transversely through its rear portion, which is secured to a bar projecting up into the leg, and forms the ankle-joint.

Fig. 2898.



Artificial Leg for Amputations below the Knee.

Le'gend. An inscription or motto in heraldry or on a coin.

Leg'gings. Wrappers used in connection with shoes or bootees, to form a protection for the legs in hunting, riding, or in rough and exposed work. They are very common among the agricultural part of the population of England, and in some parts of the continent they seem to be considered a necessary part of the hunting-costume. They are made of pliable, unblacked leather, dressed like buckskin, and are buttoned down the outer edges.

When used to protect the pantaloons or boots of an equestrian, they are sometimes called spatterdashes. One form has pliable springs in the upper edge and just above the ankle. The legging is sprung open to admit the foot, and the springs then close the legging around the leg.

The Romans had leather spatterdashes, buttoned at the sides, and probably introduced them into England. They were common among the Anglo-Saxons.

Leg and Foot Guard. (*Menage.*) A device to protect a horse's feet or legs.

They are of several kinds.

1. To prevent the cutting of the fetlock or foot by *interfering* or *overreaching*; that is, by striking the fore or hind foot against its fellow as they pass each other in motion, or striking the heel or shoe of the front foot by the toe of the hind foot or shoe.

2. To prevent the cutting of the knees in kneeling or falling forward on to the knees.

3. To prevent the unhairing or abrasion of the hide by hopples. See HOPPLE.

Rotch's flexible elastic horseshoe, patented in England in 1810, and with improvements in 1830, consisted of a sheet-metal sole and a body of india-rubber made to fit over the crown and upon the pastern. The immediate purpose of the caoutchouc cover was to hold on the sole to which a regular bar-shoe was riveted, if necessary. The india-rubber covering, in the case of *interfering* horses, was prolonged over the fetlock in order to keep the hide from abrasion by the blows of the other foot, or from being barked or cut by the toe of a hind foot in horses addicted to *overreaching*.

Fig. 2899 shows several kinds.

a has a protecting pad, which catches in the crevice between the heel and the shoe, and is fastened by a hook engaging with the clip in front.

b has a pad or fender to fit the inside of the knee-joint and ankle-joint of a horse addicted to interfering; it has also an interlining or stiffener, and a whalebone strip at the upper end of the fender to prevent the pad from turning round the leg.

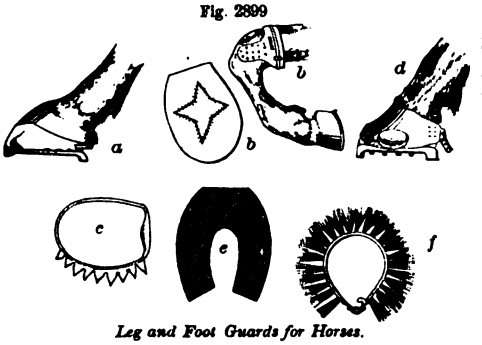
Digitized by Google

In *c*, a band surrounds the hoof at its crest, with flexible projections of caoutchouc, to prevent injury from interfering.

In *d*, the spur is inserted between the shoe and the hoof, and holds in position the inflated pad on the strap, which is secured around the hoof.

In *e*, the upper surface of the elastic inner shoe conforms to the shape of the hoof; the under surface

Fig. 2899



Leg and Foot Guards for Horses.

rests on the shoe, and the peripheral flange prevents cutting by interference.

f has a strap with bristles protruding.

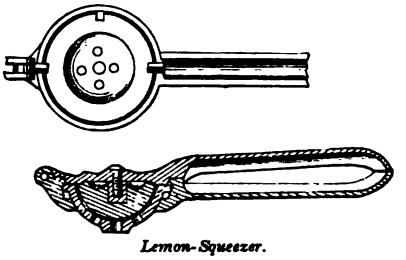
2. A lined sleeve, as a hopple-ring, to prevent abrasion of the fetlock. See HOPPLE.

3. A stout piece of leather, strengthened by a longitudinal iron plate. It is strapped to the right leg of an artillery-driver, to prevent injury from the pole of the carriage.

Leis'ter. A pronged fish-spear.

Lem'on-squeez'er. One for pressing the juice from lemons. In the example, the parts have a cup

Fig. 2900.



Lemon-Squeezer.

and a bulb respectively, and are pressed together by the handles.

The making of orangeade and lemonade was introduced into England from France about 1632. These fine acids need sugar, and this is a comparatively modern ingredient in Europe. See SUGAR.

Length'en-ing-bar. An extension-piece for the leg of a drafting compass, when the reach of the ordinary legs is insufficient.

Length'en-ing-piece. (*Shipbuilding.*) One of the timbers added to the ribs above the *top-timbers*, to impart the necessary hight to the sides of the vessel.

Length'en-ing-rod. A rod with a screw and screw-socket at the respective ends; attached endwise to form a long shank for an auger or drill in deep boring.

Le'no. (*Fabric.*) An open cotton goods, thinner than *buke-muslin*, used for veils, window-curtains, etc. It is plain, colored, or checked.

Lens. A piece of a transparent substance fashioned into a shape affording two regular opposite surfaces, both curved, or one curved and the other plane. The curved surfaces are usually spherical, and the ordinary lenses of this description are of six varieties.

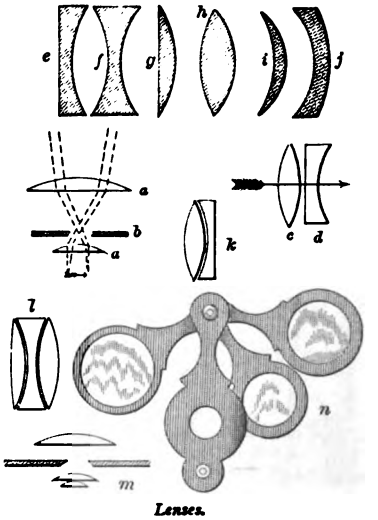
They are: —

e, plano-concave.	*h, double convex.*
f, double concave.	*i, meniscus.*
g, plano-convex.	*j, concavo-convex.*

A lens changes the direction of rays of light, diminishing or increasing the apparent size of objects viewed through it. Combinations of lenses increase this effect. For an explanation of the principles, see treatises on optics.

There are varieties of lenses peculiar from their

Fig. 2901.



Lenses.

proportions, their construction, arrangement, or their specific effects.

The *crossed lens* is a double convex, in which the radius of one face is six times that of the other.

The *polyzonal lens* is built up of several pieces arranged in zones or rings.

The *multiplying lens* is plano-convex, and its curved surface is covered with a number of plane faces or facets, each of which affords a separate image.

The *aplanatic lens* is a lens constructed of different media, so as to correct the unequal refrangibility of the different rays.

The *achromatic lens k* is a combination of a double convex lens of crown-glass and a plano-concave or a concavo-convex lens of flint-glass. The advantages of a lens formed in this manner are freedom from spherical aberration or distortion, and the rays of light are not decomposed into the primary colors; in other words, the light passes through the lens and suffers no change thereby. They were formerly combinations of three lenses, as shown at *l*. They were made by Dollond in 1753. See ACHROMATIC LENS.

The *Coddington lens* is of spherical form, and has a deep equatorial groove around it filled with opaque matter, acting as a diaphragm to diminish the quantity of light and exclude lateral rays.

A spherical silica lens is ascribed to an experiment of Sir Humphry Davy. One end of a wheat straw is ignited, and the spear is allowed to consume grad-

Digitized by Google

ually. The cinder is then heated in the blue flame of a burner, and from the silica obtained a solid globule of glass is formed, which is said to be well adapted to microscopic purposes.

A *cylindrical lens* has a body formed of a segment of a cylinder, or of two such segments united by their bases. A *Stanhope* lens.

A *diamond lens* is made from a diamond whose high refractive power is supposed to render it specially suitable for an eye-glass. Diamond lenses were made by Andrew Pritchard in 1824.

A *doublet* is an arrangement of two plano-convex lenses, invented by Wollaston, as shown at *a a*; *b* is a diaphragm. *c d* is Herschel's doublet.

A *triplet m* is an arrangement of three plano-convex lenses in a microscope. Invented by Holland.

n is also a threefold arrangement of lenses, any two or all of which may be used in combination, according to the power desired.

Eye-glass; the lens nearest to the eye in a simple arrangement, and the one nearest to the eye of the glasses forming the combination *eye-piece* of a telescope or microscope.

Compound eye-glasses are *doublets* and *triplets* (which see). See NEGATIVE EYE-PIECE.

An *immersion lens* is an achromatic objective for the microscope, which is used with a drop of water between the front lens and the cover of the object examined. See IMMERSION-LENS.

Object-glass; the *field*-glass, or the one farthest from the eye, in the combination of lenses forming a telescope or microscope.

Periscopic lens; a concavo-convex lens, the ratio of the radii of whose respective faces constitutes it a magnifying or diminishing lens; the general curve of the lens approximating that of the cornea and increasing the distinctness of the image when viewed obliquely.

Polyscope; a plano-convex lens, whose curved side has facets by which the images are multiplied. A *multiplying-lens.*

Polyoptron; a plano-convex lens, whose curved face has a number of *concave* facets which afford a number of diminished images.

The *spherical lens* is of a globular shape, and has usually an equatorial groove filled with an opaque object to exclude lateral rays. A *Coddington lens.*

The *Stanhope lens* is of a cylindrical form, and has convex ends having different radii.

It is, perhaps, impossible to determine when lenses were first made. The first observations of their effects were, no doubt, with drops of dew upon leaves, and occasionally by a spawl of crystal or a tear of vitreous matter from the inside of a furnace.

Whether the means by which Archimedes burnt the fleet of Marcellus at Syracuse was a combination of mirrors or lenses, it is hard now to determine. Probably mirrors. The same may be said of the burning by Proclus of the besieging ships of Vitalian the Scythian, at Constantinople, in the sixth century.

Refraction was observed by the ancients, and Archimedes is said to have written a book upon the subject. Plutarch speaks of instruments used by Archimedes "to manifest to the eye the largeness of the sun."

The appearance of a straight stick when thrust obliquely into water seems to have led the ancient philosophers to consider the subject. They determined that a ray of light was bent in passing from one medium to another; and Ptolemy, the astronomer and physicist, says that "the light of the heavenly bodies falling upon our gross atmosphere is bent out of its rectilinear course, which causes these luminaries to appear to rise sooner than they do in reality."

Euclid's treatise on optics was about 280 B. C. He is the one who told his royal master Ptolemy Philadelphus, "There is no royal road to learning, sir."

"Ptolemy was the first to measure refractions, and is therefore the founder of an important part of optical science." — HUMBOLDT.

"The magnifying power of hollow glass spheres filled with water (Seneca, 1, 6) was, indeed, as familiar to the ancients as the action of burning glasses or crystals (Aristoph. Nub. V. 765 [424 B. C.]) and Nero's emerald (Pliny, xxvii. 5)." — HUMBOLDT'S *Cosmos.*

Layard found in the ruin called Nimroud a plano-convex lens of rock-crystal 1½ inches in diameter and $\frac{3}{10}$ of an inch thick. It shows the marks of the lapidary's wheel. It gives a focus 4½ inches from the plane side. Sir David Brewster says, "It was used as a lens, either for magnifying or for condensing the rays of the sun." Two glass bowls were found in the same chamber. Before the discovery of the lens, it had been surmised that the minute inscriptions in the cuneiform character must have been executed by the aid of a magnifying-glass.

There are other notices of lenses scattered through the pages of antiquity. Pliny mentions that the ancients had globes of glass and crystal, and that Nero used glasses when he watched the fights of the gladiators. The old scoundrel was probably troubled with myopia, and had concave glasses. This we must suppose rather than that he had a combination of lenses similar to a telescope or opera-glass. Lactaneus says that a hollow glass sphere full of water will produce the effect of a solid sphere of glass. Iamblichus, in his "Life of Pythagoras," tells us that the latter strove to contrive instruments that should aid hearing as effectually as optic glasses and other contrivances aided sight.

Coming down from the time of Ptolemy to the revival of learning and science under the Saracens, we find that Alhazen, in the twelfth century, wrote on the refraction of rays and the magnifying power of lenses. Draper's remark here is too good to omit.

"I join, as, doubtless, all natural philosophers will do, in the pious prayer of Alhazen, that, 'in the day of judgment, the All-Merciful will take pity on the soul of Abu-r-Raihân, because he was the first of the race of men to construct a table of specific gravities'; and I will add Alhazen's name thereto, for he was the first to trace the curvilinear path of a ray of light through the air."

Abu-r-Raihân was a native of Byrun in the valley of the Indus, and a friend of Avicenna, who lived with him at the Arabian academy in Charezm. His history of India belongs to the years 1030 – 32.

Vitellio, a Pole, wrote a treatise on lenses about 1270.

The magnifying power of segments of spheres was known by the Florentine Salvino degli Armati, who died 1317.

To come down to later times, we find that spectacles were well known in the thirteenth century, and it is not known by whom they were invented. The invention has been credited to Roger Bacon (1250), and to Alexander de Spina (1280).

Roger Bacon speaks in regard to the effect of lenses as familiar, and the remarks he makes belong to the second branch of the subject, which concerns the combinations of lenses to produce the compound microscope and the telescope.

This invention consists in placing lenses of certain character at proper distances on a common axis. The character will determine the effect, and the

Digitized by Google

focal length will determine the proper distance; the common axis is imperative. Who first held two lenses in the proper relation, so as to produce an effect the result of their combination?

A few of the items in this inquisition may be noted.

Roger Bacon (1250) says: —

"We can give such figures to transparent bodies, and *dispose them in such order*, with respect to the eye and the objects, that the rays shall be refracted and bent towards any place we please; so that *we shall see the object near at hand*, or at a distance, under any angle we please. And thus from an incredible distance we may read the smallest letters, and may number the particles of dust and sand by reason of the bigness of the angle under which we may see them."

The change in apparent magnitude of distant and near objects by a proper disposition of several lenses of the required character involves the invention of the telescope and compound microscope.

In a book printed in 1551, "the glasse he [Friar Bacon] *made* at Oxford" is referred to, and the venerable philosopher is defended from the assumption that its marvels were due to the infernal power; "for," said the writer, "I know the reason to be good and natural, and to be arright by geometry, and to stand as well with reason as to see your face in a glass."

This must have been the combination of lenses referred to by Bacon, as a mere lens was well known and would excite no marvel, spectacles having been well known for three centuries, and the naked lens for a time that the memory of man runneth not to the contrary.

Frascatoro, who died in 1553, states the matter properly: "If any one will look through two lenses, one placed over the other, he will see everything much larger and clearer."

J. Baptista Porta (about 1560) states: "If you know how to combine a convex and a concave glass, one of each sort, you will see, far or near, objects larger and clearer." He is believed to have invented the camera-obscura about this time.

Dr. Dee says (1570) that "perspective glasses" will enable a commander to ascertain the strength of an enemy's forces; referring apparently to an optical instrument then in use.

Leonard Digges (about 1571) appears to have been able, "by proportional glasses duly situate," to discover things afar off, read letters and inscriptions on coins at a distance, and tell what was passing seven miles off. Such is the claim in his son's book, second edition, published in 1591.

Jansen (about 1608), a spectacle-maker of Middleburg, Holland, was struck by the effect of a concave and a convex lens held in the proper relation and distance. For the purpose of observation, he fixed the glasses on a board in proper position, and afterwards in a tube. He seems to have considered it interesting but not valuable, and Prince Maurice of Nassau became possessed of it.

Lippersheim, also of Middleburg, seems to have been concerned in it in some way.

Another claimant of the invention about the same date is Metius, who was a glass-cutter, and casually observed the effect of a concave and convex lens held in line in the hands. The three latter claimants had their supporters as the authors of the invention.

Descartes, who lived near the time, supported the claims of Metius. Borelli, about 1650, examined the question, and decided in favor of Jansen and Lippersheim. Porta is said to have hastened his death, which happened in 1615, by the fatigue and anxiety incurred in supporting his claims.

Galileo had a hint of the invention, studied it out, and made a telescope which he soon put to use. See TELESCOPE.

Kepler (1571 – 1630) was, perhaps, the first to state with precision the effects of lenses in making the pencils of light converge or diverge. He showed that a plano-convex lens makes rays that were parallel to its axis to meet at the distance of the diameter of the sphere of convexity; but that if both the sides of the lens be equally convex, the rays will have their focus at the distance of the radius of the circle corresponding to that degree of convexity.

Cavallieri laid down the rules in regard to lenses whose sides are unequally convex. As the sum of both the diameters is to one of them, so is the other to the distance of the focus. The rule for convex glasses is applicable to concave, with the difference that the focus is on the contrary side of the glass.

Kepler, in his "Catoptrics," explains the rationale of the system of lenses in a telescope. Scheiner constructed one on this principle in 1630. His description is as follows: "If you insert two similar lenses (that is, both convex) in a tube, and place your eye at a convenient distance, you will see all terrestrial objects, inverted indeed, but magnified and very distinct, with a considerable extent of view." He afterward added two more glasses, which reversed the image and brought it to the natural position.

Rheita was the first to employ the combination of three lenses, the *terrestrial telescope*.

Snellius of Leyden, Descartes (1596 – 1650), and Leibnitz (1646 – 1716) stated the doctrine of refraction more or less fully; and Grimaldi, an Italian painter, demonstrated the ellipticity of the sun's image after refraction through a prism; Newton (1642 – 1727) determined that it was owing to the difference in the refrangibility of the respective portions of the rays.

Newton supposed that *refraction* and *dispersion* were indissolubly united, but Dollond demonstrated that by using two different kinds of glass he could abolish the color, and yet leave a residue of refraction.

Refraction has reference to the deflection of the ray, *dispersion* to the diverging of the components of the ray, incident to the different refrangibility of the parts of which it is constituted. *Dispersion* is therefore *decomposition*, while *refraction* is *bending* at an angle. The *direction* of the dispersion depends upon the form of the surface on which the ray impinges; the *extent*, upon the nature of the medium. The flat face of a vertical prism gives a strictly lateral divergence, and simply widens the image, the colors resulting from the decomposition taking up their places in parallelism, the red as the least refractive at one edge, and the violet as the most refractive at the other edge. There is also a non-visible portion of spectrum at each end; *heat* at the *red* end, *actinium* at the violet end.

The amount of *dispersion* of light, or the length of the spectrum formed by prisms having the *same refracting angle*, varies greatly in different media. Newton supposed that the *dispersion* was always proportional to the *refraction*, but Dollond ascertained that although the average *refraction* of the ray might be the same in two media, yet the *dispersion* or diverging effect might be much less in one than in the other.

Euler (1707 – 83) was the first to state that it must be possible to produce an achromatic lens by using media of different densities. Dollond, in trying by experiments to disprove this supposition,

Digitized by Google

proved its truth. He adopted flint and crown glass, which have a difference in refractive powers in favor of the latter, accompanied by a still greater difference in dispersive powers in favor of the former. He took two lenses, one concave and the other convex, — which are, in effect, equal to two prisms refracting in different ways, — so arranged that the *dispersive* powers of the flint-glass would be corrected by the crown-glass, and the image produced by the excess of refraction of the latter would be sufficiently colorless for the purpose.

The difficulties incident to procuring lenses of homogeneous quality, large size, and free from striæ, have been very great, and deserve a passing notice. Sir Isaac Newton declared them insurmountable, and the English, French, and Germans of the last century labored hard at the problem. The Academy of Sciences at Paris offered prizes, and subsequently a commission consisting of Herschel, Faraday, Dollond, and Roget were instructed to pursue the inquiry. The excise system of England at that time sat like a foul bird upon all the nests where glass was hatched, and prevented the experiments, tying the hands of this noble quarternion of philosophers with a few yards of red tape applied by some seedy-looking individual, with a pen behind his ear and no speculation in his eye.

Munich at last carried the palm; her skill being originally derived from Guinand, a poor peasant of Neufchatel, Switzerland, who was brought up to the watch-trade. He made experiments, and gradually shifted himself into the manufacture of optical instruments, finally allying himself with Utzschneider and Frauenhofer of Munich, whose establishment yet has a world-wide reputation: he succeeded in soldering glass. Pure disks of flint-glass were exhibited in London in 1851, having a diameter of 29 inches and weighing 224 pounds.

Guinand's mode of making lenses is stated by Mr. Pellatt to have consisted in stirring the glass while at the highest point of fusion; cooling down the entire contents of the pot in a mass, and when annealed and cooled, separating unstriated portions by cleavage, afterwards softening the piece in clay molds which gave the shape. The plan has been pursued by his successors.

A powerful lens was made some years since by Parker of London. It was of flint-glass, 3 feet in diameter; 3¼ inches thick at the center; focal distance, 6 feet 8 inches; diameter of the burning focus, 1 inch; weight, 212 pounds. The rays refracted by this lens were received on another, the diameter of which in the frame was 13 inches, and its focal length 29 inches. This reduced the diameter of the burning focus to ½ inch, quadrupling its power. It cost $3,500, and melted: —

Pure gold	20	grains in	4 seconds.
Silver	20	"	3 "

Wood burned immediately; water flashed into steam; bones fell into a calcined form at once.

This glass was carried to China by Lord Macartney, and was left in Pekin. It was probably stolen or destroyed in the sacking of the summer palace by the allies.

A flint-glass lens, weighing 224 pounds, was exhibited at the London Exposition, 1851.

A burning-lens of great power may be obtained by fixing two circular disks of thin glass at the opposite ends of a tube, say 1 inch long, and injecting into the space between them, under pressure, turpentine, bleached oil, or other liquid of high refractive power. When the glass attains the required curvature, close the stop-cock and mount the fluid-lens for use.

The lens of the new Naval Observatory at Washington has been made by Alvan Clarke & Sons, of Cambridgeport, Mass. It is 26 inches in diameter; the telescope is now in working position in the building erected for it under the superintendence of Professor Newcomb.

(*Lens Grinding.*) Lenses are so ground that their faces shall form a portion of a spherical surface. The tools employed are, first, a concave shell of cast-iron (*a*, Fig. 2902). This is cast from a wooden pattern of the true curvature of the lens, formed by means of a templet having a radius equal to that of the required curve, and by it, with the aid of coarse emery, the lens is ground approximately to the true form. Two templets, one convex and the other concave, are made of sheet-brass or copper, or, for large-sized lenses, of crown-glass. These serve as guides for turning the convex and concave tools *b c* to a proper sphericity.

The piece of glass of which the lens is formed is clipped around the edges to bring it to a circular form by means of flat pliers of soft iron, which does not slip from the glass as steel would, leaving it of somewhat greater diameter than the finished lens, and is then attached, by means of cement, to a concave, circular holdfast, somewhat smaller than the

Fig 2902.

Lens-Grinder.

lens. The concave tool *a* is now used for bringing the glass to a spherical surface. For this purpose emery is employed, coarser at first and then finer, as the face of the lens begins to assume its true form. The tool *a* is turned both circularly and transversely of the lens, so as to bring the two surfaces in contact in every possible position in order to insure perfect sphericity. From time to time the concave tool *b* is ground in a similar way upon the convex tool *c*, in order to preserve the correctness of its surface.

Digitized by Google

The lens is polished in one of the iron shells *a*, the interior of which is coated with cement, over which a piece of cloth is placed and pressed into shape by the convex tool. This is covered with putty powder (peroxide of tin). The manipulations are similar to those just described. Finally, the edges of the lens are ground to their true diameter.

d is a convex tool or *runner* of cast-iron, of about ½ inch less radius than the templet, used as a support for common glasses, a number of which are ground together.

Another contrivance for polishing lenses and other bodies of spherical form consists of a cup connected by a ball-and-socket joint and a bent arm, with a rotating upright shaft set concentric to the body to be polished. The cup, being set eccentrically on the joint, has an independent rotation at the same time that it revolves around the common axis. This prevents any part of the surface of the cup from coming repeatedly in contact with the same parts of the body which is being ground or polished.

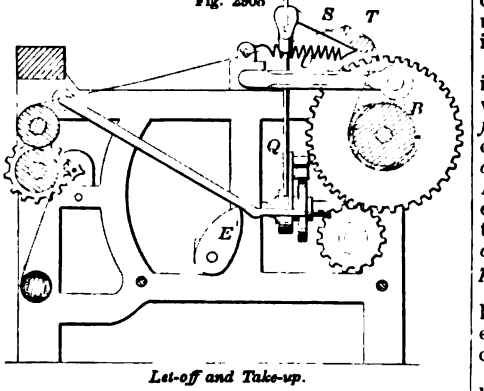
Len-tic'u-la. A small lens.

Le-pine'-watch. A flat form of watch, invented by Lepine of Paris.

The wheels are held by bars, technically called *cocks*, instead of being pivoted in two parallel circular plates.

Let-off. (*Weaving.*) An arrangement in a loom by which the yarn is paid off from the beam at such a rate as it shall be required by the weaving-process, and which is dependent upon the rate of the *picks*,

Fig. 2903



Let-off and Take-up.

the sizes of the warp and weft thread, the compactness with which it is beaten up by the lay. The *take-up* is the winding on to the *cloth-beam* of the completed web, and proceeds coincidently with the *let-off* from the *yarn-beam*. Regularity of *let-off* is secured by making the rate of surface motion of the *yarn-beam* depend upon the tension of the yarn; and the rate of revolution of the beam, to secure equal speed of let-off, will become rapid as the bulk of yarn diminishes upon the roller. The devices for this purpose are numerous. In the example, the same cam *E'* operates both the *take-up* and *let-off* devices; the strain of the yarn on the *whip-roll T* operates through the arm *S* and rod *Q*, pawls which act upon the ratchet by which the yarn-beam *B* is rotated.

Let'ter. (*Printing.*) A character used in printing. Type either of metal or wood. Used collectively to represent type, as "a case of letter," "a font of letter."

Fat letter; a type with body and face broad in proportion to its hight.

Lean letter; type thin or narrow in proportion to its hight.

Body letter; that type in which the main portion of a book or paper is printed. It consists generally of a font of type containing Roman CAPITALS (caps.), SMALL CAPITALS (small caps.), small letters (lower case), with a proper proportion of *ITALIC CAPS.* and *italic lower-case* letters. Technical works require numerous sorts in addition to the above. See FONT.

Body letter is distinguishable by the size of the type, those in most common use being —

Pearl.
Agate.
Nonpareil.
Minion.
Brevier.
Bourgeois.
Long Primer.
Small Pica.
Pica.

Half-minion, *half-brevier*, and *diamond*, sizes smaller than *pearl*, are used in notes of reference, side-notes, etc., but rarely for body letter. *English*, *Columbian*, *great primer*, and *paragon*, larger than *pica*, are used in circulars, display, and some legal works. Sizes larger than these are multiples of a smaller body (generally pica, known as 2-line pica, 3-line pica, etc.), and are used in printing posters. The body of letters differs with various type-founders. Nonpareil is generally about one twelfth of an inch; i. e. twelve lines of nonpareil measure one inch down the column. Pica is double nonpareil; 12-line pica type, therefore, measures about two inches in hight.

Letter is characterized by various names, according to the face. Besides *roman* and *italic* body type, which may be *old-style*, *new-style*, *Scotch-face*, *light-face*, *hair-line*, etc., job printers use a great variety of letter in the varied styles of printing. *Gothic*, *antique*, *Runic*, *Celtic*, *black*, *German text*, *Old English*, *script*, *title*, and scores of others might be enumerated. Nearly all of these, besides being cast to all the sizes before mentioned, are made *extra condensed* (very lean), *condensed*, *standard*, and *expanded* (fat).

Type-founders, to supply all the orders they are likely to receive, are compelled to keep on hand several thousand varieties of letter, or the matrixes for casting them.

Ascending and *descending* letters extend respectively above and below the general level of the line. b d l are examples of the former, p q y of the latter.

Kerned letter. Where some portion of the face overhangs the body, as the dot of an f. Nearly all the long letters in italic and script fonts are kerned.

Accented letter (see FONT).

Let'ter-bal'ance. A device to weigh letters for mailing. See LETTER-SCALE.

Let'ter-board. (*Printing.*) A board on which pages or columns of type are temporarily placed.

Let'ter-box. One to receive letters.

1. A locked box attached to a post in the public street, for convenience of mailing, the letters being gathered from time to time by carriers.

The box (Fig. 2904) is for attachment to a lamp-post. The letter-passage in the top has a cover whose cam-projection operates a lever inside, and the lever is connected to the free edge of the hinged plate, so as to close the aperture between the plates when the lid is raised. When the lid is closed, the letter slides off the plates through the aperture.

2. A box attached inside a door to catch the letters and cards left by carriers or callers. The

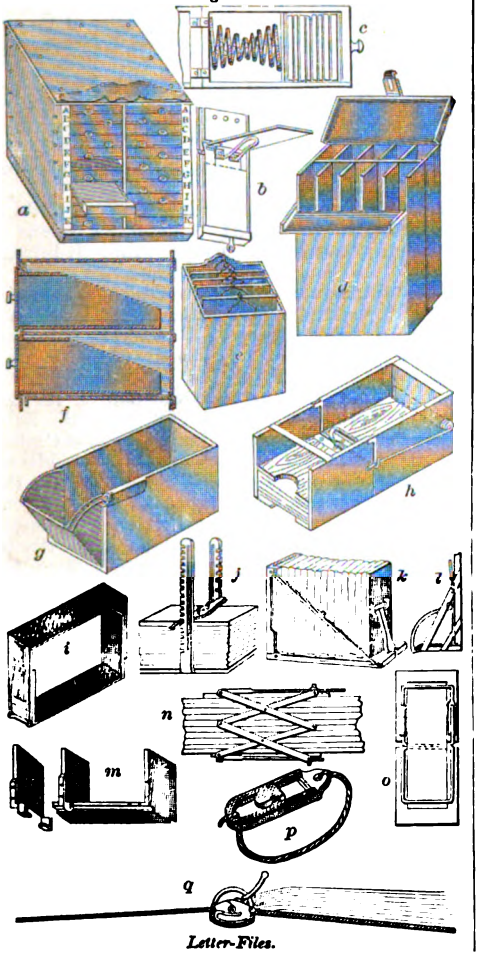
Office-Door Letter-Box.

door-plate has provision for a slip containing the name of the occupant, and has a flap covering a chute leading to a letter-box, whose serrated plate prevents the surreptitious abstraction of letters from the outside.

3. An office-box to hold letters accumulating during the day, awaiting mail-time.

Fig. 2906.



Letter-Files.

Let'ter-case. 1. (*Printing.*) A partitioned tray in which assorted letters are placed. A *case.*

2. A portfolio.

Let'ter-clip. A spring-clasp to hold letters or other memoranda together.

Let'ter-file. A box, case, folio, or envelope, for containing letters to which reference is required to be made.

a is case with labeled drawers.

b is one of the drawers belonging to *a*, having a spring flap to hold down the letters.

c is a drawer with a spring to compact the letters against the end.

d is a box with labeled divisions and falling flap and lid.

e has pockets with lifters.

f has trays which slide into cases.

g is a tray with a let-down front.

h is a tray with a spring follower to keep down the letters compactly.

i has two three-sided pieces, which are drawn together by springs to embrace the papers.

j has racks with notches which hold the cross-bar upon the follower-board above the pile of letters.

k has a tray with a back, and a brace which locks against the pressure-board.

l shows a pressure-board held against the papers by a spring.

m has a shifting-board which may be rigid in any position. On the left, the shifting-board is shown separately.

n has a lazy-tongs arrangement to connect the two boards.

o has a spring wire-clamp.

p has a cord and locking-plate.

q has flaps like a portfolio, and a binding-clamp at the back.

Let'ter-ing-box. (*Bookbinding, etc.*) A case to hold a set of movable type when composed to form a name or address, for lettering books, marking linen, etc.

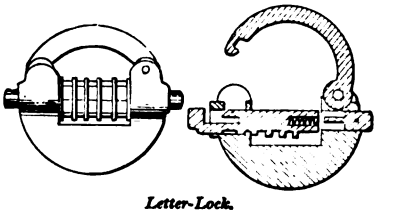
Let'ter-ing-tool. A bookbinder's tool for stamping the gilt titles on the backs of books. For titles in common use, as "Atlas," "Holy Bible," etc., the whole word or words are cut on the face of the tool. In other cases movable type of various sizes are provided, which are adjusted in a slot fitted to receive them.

Fig. 2907.

Lettering-Tool.

Let'ter-lock. A lock whose bolt is surrounded by several rings having notches through which a set of studs on the bolt must pass before the lock can be opened. These notches are so arranged as to prevent the passage of the bolt except when certain letters on a series of exterior rings are brought into line with each other so as to form a particular word or combination on which the lock has been set.

Fig. 2908.



Letter-Lock.

Digitized by Google

It is mentioned in Beaumont and Fletcher's play of "The Noble Gentleman," 1615.

"A cap-case for your linen and your plate,
With a strange lock that opens with A. M. E. N."

Regnier, about the middle of the seventeenth century, made improvements in the letter-lock, and is generally credited with its invention, though this has been contested. His lock is thus described: "Broad steel rings, four, five, or eight deep, upon each of which the alphabet was engraved, turned upon a cylinder of steel, and the lock only separated when the letters forming a particular word were in a straight line with one another. This word was selected from among a thousand, and the choice was the secret of the purchaser. Any one not knowing the word might turn the ring round for years without finding the right one."

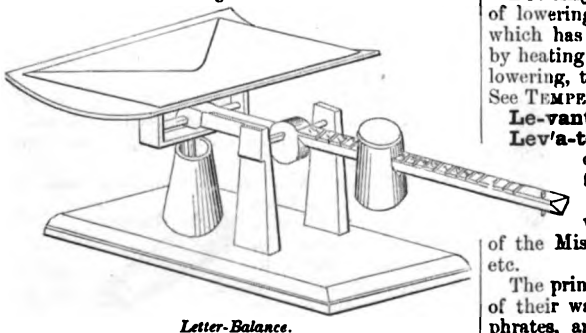
Let'ter-pa'per. (*Paper.*) Paper of post or note size, for epistolary use. The ordinary size of post is 10 × 16 inches when *flat*, and 8 × 10 when folded. Note-paper is smaller, and varies in size much.

Let'ter-press Print'ing. The ordinary form of printing in which the salient device is inked and the ink transferred to a sheet which is pressed thereupon. See PRINTING.

Let'ter-punch. A steel punch having a letter engraved on its end. Such are used to make matrixes for type; also to mark other articles of metal by giving an impression thereon when struck by a hammer.

Let'ter-scale. A balance for weighing letters and papers for mailing. That shown has a graduated beam with figures upon its flat, upper side.

Fig. 2909.



Letter-Balance.

Other forms are suspensory, having spiral springs, or rest upon a stem supported by a spring.

Let'ter-stamp. A form of stamp for defacing postage-stamps; or for attaching the place of mailing, destination, notices for carrier, deficient postage, "too late," "forward," and what not.

The United States Post-Office Department uses a hand-stamp for postmarking letters and canceling or defacing their postage-stamps. The tool consists of two small cylinders about an inch apart, fastened to a wooden handle. One cylinder bears type for the postmark, which may be removed and changed. The other cylinder carries a cork, its face generally cut in the form of a star, cross, or some fanciful device. This cork is struck upon the postage-stamp by the same blow which imprints the postmark upon the envelope. The stamp is inked by a dab upon a piece of printers' roller-composition. Letters to be postmarked are spread out upon a table covered with leather or rubber, and are postmarked and their stamps canceled as fast as blows can be struck with the postmarking and canceling stamp, or, when the latter is in the hands of an expert, nearly as fast as a person can count.

Stamps bearing such legends as "3 due," "missent," "forward to writer," etc., are small sticks of boxwood, about 4½ inches long and 1 inch in diameter, turned to a handle at one end, and the words engraved on the other. They are struck upon the letters in the same way as the postmarking and canceling stamps. Metallic stamps were formerly used for this purpose, but they have been nearly or quite superseded by those of wood.

In the General Post-Office, London, 140 stamp-canceling machines are employed. The object is to deface the stamp on letters, and impress the date, which can be done with one machine at the rate of 200 letters per minute. It consists of an apparatus in which the letters are ranged in rows, and has a double joint, so that it can run to and fro with a range of about a yard. The dies, of which there are two, — one for effacing the postage-stamp, and one for impressing the date, — are fixed to one frame, and are inked by the same roller, which is always kept in contact with a long porous pad, curved, to coincide with the path of the roller, as it runs down to pass over the dies, or up out of their way. The ink-reservoir lies on the pad, which is kept saturated. One blow from the hand of the operator impresses both stamps. Four stout wires around the effacing-die project a little beyond it, so that in stamping letters with bulky inclosures, the portion of the envelope to be stamped may be pressed flat before it is brought into contact with the die.

Let'ting-down. (*Metal-working.*) The process of lowering the temper of a steel tool or spring, which has been made flint hard and then reduced by heating to the degree of hardness required. In lowering, the temper is known by the color reached. See TEMPERING.

Le-vant'ine. (*Fabric.*) A kind of silk cloth.

Lev'a-tor. (*Surgical.*) A lever for raising a depressed portion of the skull. It belongs to the trephine case.

Lev'ee. An embankment to restrain water, and of a magnitude such as those of the Mississippi, Ganges, Holland, Po, Thames, etc.

The principal rivers noted for the periodical rising of their waters are the Nile, the Ganges, the Euphrates, and the Mississippi. Of these, the Nile, which flows from the mountains and lakes of Central Africa, begins to rise in June, and by the middle of August attains an elevation of 24 to 28 feet in the upper country, and less towards the mouth, the inundation flooding the cultivatable valley of Egypt. The Egyptian embankments are described by Herodotus and Strabo. The Ganges, flowing from the Himalayas, rises 32 feet from April to August, and creates a flood of 100 miles in width. The Euphrates, from Mount Ararat, rises 12 feet between March and June, and covers the Babylonian plains. The Mississippi rises with the melting of the snows, its various tributaries, the Missouri, Ohio, Arkansas, and Red rivers, turning in their supplies from the elevated interior regions. At a distance from the ocean its rise is 50 feet, while nearer the sea its rise is considerably reduced by the vast tract which it covers.

The Mississippi was discovered by De Soto, 1542, and explored at its upper end by Father Marquette and M. Joliet about 1672. M. La Salle traversed its whole length in 1677, and De Iberville was the first to enter it from the sea.

The dikes of Holland are marvelous, and are referred to under DIKE, DRAINING (which see). The Haarlem Lake is one of the latest recoveries from the

Digitized by Google

sea. It was 15 miles long and 7 broad, and was drained by embanking and pumping, the work being completed in 1852. Three steam-engines were employed for several years. (See PUMPING-ENGINE; also pages 116, 739.) It is now proposed to inclose and pump out the Zuyder Zee, a part of which was once habitable but was overwhelmed by a storm which tore down the dikes.

It has been calculated that nearly nine hundred thousand acres have been gained in the Netherlands by diking and draining. The province of Zealand consists of islands washed by the sea on their western coasts, and separated by the many channels through which the Schelde and some other rivers find their way to the ocean. In the twelfth century, these islands were much smaller and more numerous than at present. They have been gradually enlarged, and, in several instances, at last connected by the extension of their system of dikes. Walcheren is formed of ten islets united into one. At the middle of the fifteenth century, Gœree and Overflakkee consisted of separate islands, containing altogether about ten thousand acres. By means of above sixty successive advances of the dikes, they have been brought to compose a single island, whose area is not less than sixty thousand acres. The first dikes of Holland are attributed to the Romans.

A levee 6,000 yards in length defends the Romney Marsh, Essex, England, from overflow by the sea. The levee was made during the occupancy of Britain by the Romans, and is kept in good order, 24,000 acres of rich land being thus obtained. The fresh water in the ditches passes off at the lowest state of the tide by three sluices.

In Lincolnshire, England, 400,000 acres of fever-and-ague breeding swamp-land have been transformed into fields of wheat, barley, and oats, and excellent meadows. See SCOOP-WHEEL.

Lev'el. An instrument for indicating a horizontal line, or determining the position as to horizontality of an object or surface to which it is applied. See also CONTACT-LEVEL.

The Roman instruments for leveling were the *libra aquaria* and the dioptera of Hipparchus, the father of astronomical geography. The name is derived from *libella*, Lat. a balance, from the similarity in form, the long arm and perpendicular post. The word *libro* meant to level or to weigh.

The *libra aquaria*, we may deduce from Vitruvius, to have been a tube with upturned ends and holding water. It was probably mounted on an axis so as to be oscillated like a balance (*libra*), to adjust it on a vertical plane. Vitruvius remarks that Archimedes had stated that a surface of water was not level, as it partook of the convexity of the earth, yet, he observes, the water will rise in the ends of the tube to an equal hight if the instrument be held level.

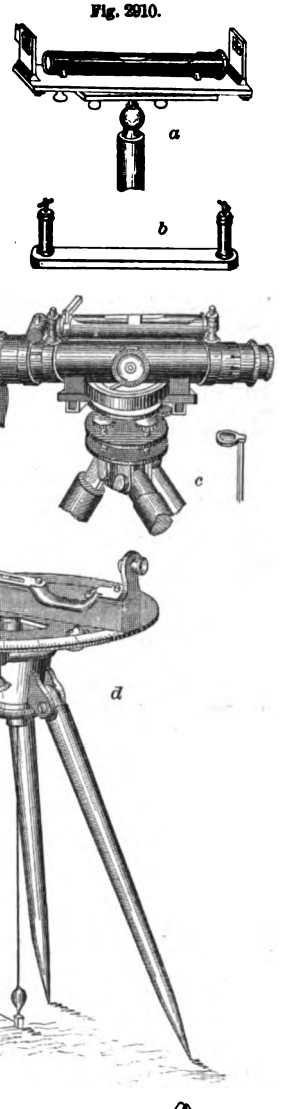
"The surface of water is not flat, but, on the contrary, convex, of a spherical shape. On this account, one who is on the sea, with a lighthouse in the distance, first descries its summit, and afterwards makes out to discover, little by little, what is below the summit, all of which was before, as a matter of course, concealed; for, excepting the convexity of the earth, there is nothing to hide every other part but the summit, in the case supposed." — AL KHÂZINÎ (twelfth century) in "The Book of the Balance of Wisdom."

Al Khâzinî was at the court of, and dedicated this work to the Saljûke Sultan Sanjar, who reigned over a large part of the Khalifate of Bagdád, 1117–57. It is not clear that he was identical with Alhazen, the Iberian Saracen. (See pages 141, 212, 1154.)

Another Roman level was the *chorobates*, which was a light wooden frame about 20 feet in length, and mounted on a leg at each of its extremities. The longitudinal piece and the end pieces were braced by diagonals marked with vertical lines. A plumb-line suspended at each extremity swung over a diagonal, and indicated, by reference to the line, the horizontality of the instrument. It was much like the modern level.

When the wind disturbed the quietude of the plumb-line, a channel in the upper edge of the horizontal bar was filled with water. When the water equally touched each end of the channel, the instrument was considered level.

Fig. 2910.



Levels.

Mariotte's level has a long surface of water made so as to reflect to the eye an inverted image of the object, the point where the two objects appear to meet being on a level with the place where the surface of the water is found.

Cassini's level has a steel mirror placed a little before the object-glass of a telescope, suspended pependicularly. The mirror makes an angle of 45° with the telescope, when the latter is brought to the horizontal or level line.

The spirit-level, used by carpenters and builders, is an instrument consisting of a straight bar with a slightly curved glass tube containing alcohol. The tangent of the tube

Digitized by Google

is the straight-edge of the instrument. For surveyors, the instrument is mounted on a stand and tripod and provided with sights, for use in leveling. One form is shown in the illustration (*a*, Fig. 2910). The spirit-tube is inclosed in a brass case and mounted on a stand, whose end plates are pierced for sights. Screws beneath the bed-plate permit accurate adjustment. Invented by Thevénot.

A description of his instrument, accompanied with figures, was first published in the "Journal des Savants," Paris, November 15, 1666, under this title: "*Machine nouvelle pour la conduite des eaux, pour les bâtiments, pour la navigation, et pour la plupart des autres arts.*" The instrument is there called an air-level; and is described as a glass tube, hermetically sealed at both ends, containing spirits of wine, which do not freeze, and a small quantity of air forming a bubble. It is stated that the instrument is capable of giving, with much exactness, the direction of the horizon, the perpendicular to the horizon, and vertical angles; and that it is easier to make, more convenient to use, and indicates a level line more readily and accurately than any other instrument.

Parker's level (*b*) consists of a glass tube of small bore, the two ends being bent at right angles and closed. The ends are about three inches high, and marked at a certain level; the tube is charged with quicksilver, so as to stand at the marked point in the tube-ends. Floats resting on the surface of the mercury have stems which pass outside and support sights through which objects are viewed. The instrument is supported on a tripod.

Gravatt's surveyor's level (*c*) consists of a telescope provided with spirit-levels. It is furnished with screws for minute adjustment, and is mounted on a tripod.

Sibley's level (*d*) is made of cast-iron, and is a cheap form of the instrument, possessing sufficient accuracy for common uses.

At one end it is provided with a sight having a small aperture with a short tube attached. At the opposite end of the level is a ring with cross wires, so adjusted that the center of the sight aperture and the intersection of the wires are level when the bubble at the center indicates that the instrument is level.

The level stands on a circular graduated table, from the center of the under side of which is suspended a plumb in the usual manner. This plumb being adjusted over any point (as the corner of a building-lot) and the first line laid out, stakes can be set in a line drawn at any desired angle to the first line, by simply turning the level upon a central pivot, provided for that purpose, the required number of degrees as indicated on the graduated table.

Brown's level (*e*) is shaped like a pair of compasses; the cross-bar, which is marked at midlength, shuts up between the legs when closed for transportation, in which condition the instrument resembles a walking-stick. It has the usual plumb-line.

The level is used to find a line parallel to the horizon. Practically speaking, two places are on a level which are equally distant from the center of the earth, but as the line of sight is a tangent and does not follow the curvature, in an observation, the excess of the apparent over the true level will be 7.9618 inches at a station a mile distant from the point of observation. Hence, proportioning the excesses in altitude according to the square of the distances, the following table is obtained, showing the hight of the apparent above the true level for every 100 yards of distance on the one hand, and from ¼ of a mile to 14 miles on the other.

Table.

Distance in Yards.	Difference of Level in Inches.	Distance in Miles.	Difference of Level in Feet and Inches.
100	.026	¼	0.05
200	.103	½	0.2
300	.231	¾	0.45
400	.411	1	0.8
500	.643	2	2.8
600	.925	3	6.0
700	1.260	4	10.7
800	1.645	5	16.7
900	2.081	6	23.11
1,000	2.570	7	32.6
1,100	3.110	8	42.6
1,200	3.701	9	53.9
1,300	4.344	10	66.4
1,400	5.038	11	80.3
1,500	5.784	12	95.7
1,600	6.580	13	112.2
1,700	7.425	14	130.1

Hebert gives the following illustrations of the useful application of the table: —

This table is adapted to several useful purposes.

First. To find the hight of the apparent level above the true at any distance.

If the given distance is in the table, the correction of the level is found in the same line with it; thus, at the distance of 1,000 yards, the correction is 2.57, or about 2½ inches, and at the distance of 10 miles is 66 feet 4 inches. But if the exact distance is not found in the table, then multiply the square of the distance in yards by 2.57 and then divide by 1,000,000, or cut off six places on the right for decimals, the rest are inches; or multiply the square of the distance in miles by 66 feet 4 inches, and divide by 100.

Secondly. To find the extent of the visible horizon, or how far an observer can see from any given hight on a horizontal plane, as at sea, suppose the eye of the observer, on the top of a ship's mast at sea, is at the hight of 130 feet above the water, he will then see about 14 miles round; or from the top of a cliff by the seaside, the hight of which is 66 feet, a person may see to the distance of nearly 10 miles on the surface of the sea. Also, when the top of a hill, or the light in a lighthouse, or such like, whose hight is 130 feet, first comes into the view of an eye on board a ship, the table shows that the distance of the ship from it is 14 miles, if the eye is at the surface of the water; but if the hight of the eye in the ship is 80 feet, then the distance will be increased by nearly 11 miles, making in all about 25 miles in distance.

Thirdly. Suppose a spring on one side of a hill and a house on an opposite hill, with a valley between them; that the spring seen from the house appears by a leveling instrument on a level with the foundation of the house, which, suppose, is a mile distant from it; then is the spring 8 inches above the true level of the house, and this distance would be barely sufficient for the water to be brought in pipes from the spring to the house, the pipes being laid all the way in the ground.

Fourthly. If the hight or distance exceed the limits of the table, then first, if the distance be given, divide it by 2, by 3, or by 4, etc., till the quotient comes within the distances on the table; then take out the hight answering to the quotient and multiply it by the square of the divisor, that is, by 4, 9, 16, etc., for the hight required. Thus, if

Digitized by Google

the top of a hill is just seen at the distance of 40 miles, then 40 divided by 4 gives 10, the answer to which in the table is 66⅔ feet, which being multiplied by 16, the square of 4, gives 1,061⅓ feet for the hight of the hill. But when the hight is given, divide it by one of those square numbers, 4, 9, 16, 25, etc., till the quotient comes within the limits of the table, and multiply the quotient by the square root of the divisor, that is, by 2, 3, 4, or 5, etc., for the distance sought; so when the top of the Peak of Teneriffe, said to be about 3 miles or 15,840 feet high, just comes into view at sea, divide 15,840 by 225, or the square of 15, and the quotient is 70, nearly; the answer to which in the table is by proportion nearly 10¾ miles; then multiply 10¾ by 15, = 154¾ miles for the distance of the Peak.

In what has been stated, no regard has been paid to the effect of refraction in elevating the apparent places of objects. But as the operation of refraction, in curving the rays of light proceeding from objects near the horizon, is considerable, it can by no means be neglected when the difference between the true and apparent elevation is estimated at considerable distances. It is now ascertained that, for horizontal refractions, the radius of curvature of the curve of refraction is about 7 times the radius of the earth; in consequence of which, the distance at which an object can be seen by refraction is to the distance at which it would be seen without refraction nearly as 14 to 13, — the refraction augmenting the distance at which an object can be seen by about $\frac{1}{13}$ of itself. By reason of this refraction, too, it happens that it is necessary to diminish, by $\frac{1}{7}$ of itself, the hight of the apparent above the true level, as given in the table of reductions. Thus at 1,000 yards, the true difference of level, when the allowance is made for the effect of refraction, will be 2.570 − .367 = 2.203 inches. At 2 miles it would be 32 − 4.5 = 27¾ inches, and so on.

A *level* tube, in order to be accurate, must be ground in the inside surface, against which the bubble plays, to a concavity, the curvature of which is determined according to its length of radius, and which again is governed by the sensitiveness or accuracy of reading required. For a common leveling-instrument, for instance, a curvature of 150 feet radius is all-sufficient, while for astronomical determinations radii of from 700 to 1,200 feet are often required. Unground tubes, although frequently used, are utterly unreliable, and even among the ground ones many are found that show in their length great inequalities of radius. This arises from the difficulty of shaping and using skillfully the metallic mandrel or core on which the glass tube receives its form, since it has to be formed empirically and by trial, no arrangement being possible by which the form of the mandrel could be otherwise tested. Very similar to the shaping of large lenses for telescope objectives, the forms must be corrected by frequent trials of the result.

The mandrel on which the tube is ground to an arc of a given radius has a strip, say 60° of its surface, which corresponds in its curve with the interior diameter of its tube and the camber or arc required; but the mandrel is so much smaller than the tube that the latter may be reciprocated upon it, both in the rotary and longitudinal directions, the motions, in fact, being a combination of the two, much as in grinding lenses, allowing for the difference due to the motion of a tube on a mandrel and a lens on its shaping-block. The tube is thus ground with flour emery, and then with polishing powder, upon a surface the exact counterpart of the shape required, the different portions of the tube being brought in succession to the said grinding-surface by the rolling, or, as it may be called, figure-of-8 motion described. The length of the grinding strip on the mandrel should bear a given relation to the length of the tube, so that not alone should the tube receive an equal action at each part of its length, but the grinding-surface itself may retain its shape unimpaired. The excess of length of the mandrel may be, say, one quarter greater than that of the tube.

The longer the radius to which a tube is ground, the lesser will be the versed sine of the arc relatively to the chord, and the longer will be the seconds division of the graduations of the tube. One second (1″) of arc is equal to $\frac{1}{206000}$ part of the radius of the circle of which the tube is an arc. A level-tube ground to a radius of 1,000 feet will have its second (1″) graduations 0.058783 + of an inch apart, nearly $\frac{1}{17}$ of an inch. The level-trier constructed and used by Mr. Würdemann (the eminent optical and surveying instrument maker, of Washington, D. C., to whom I am indebted for the present detailed information) has second (″) graduations of 1 millimetre, and is ground to a radius of about 680 feet.

The English practice is to imbed the level-tube in plaster in a brass case, with an opening exposing the range of the bubble, in which condition it is subject to all the contractions and expansions of its envelope, a little more pressure upon any one part of the tube than on any other throwing the tube out of true, so that given lengths of different parts of the tube have a different value. Mr. Würdemann, on the contrary, suspends the tube as independently as possible, putting a band of paper around each end of the tube and clamping it in its brass holder by numerous white-pine wedges, leaving the greater length of the level free, suspended between the ends.

It appears from what has been said in the earlier portion of this article, that water was the liquid first employed in leveling, but at a distant period wine and eventually spirits came to be employed to avoid the difficulty due to freezing of the liquid. This change was also an improvement in respect of the greater mobility of the liquid. The comparative sluggishness or viscidity of a liquid is expressed in the time that a bubble of air takes to traverse a certain distance in a certain sized tube.

The result is expressed by water, 100; alcohol, 15; sulphuric ether, 5; chloroform, 3.

The English make long level-tubes apparently to avoid the difficulty arising from the expansion and contraction of the liquid, which decrease and increase, respectively, the size of the bubble. The American practice is to make short levels, and this has been rendered possible by placing a chamber at the end, into which any portion of the air of the bubble, short of the whole, may be admitted and detained, so that a bubble of an equal size may be attained when working at various temperatures. The *chambering* of the level-tube was introduced by Pistor and Martins, instrument-makers of a European reputation. The chamber is made by cementing a glass partition near one end of the tube, a small hole on the edge of the glass disk making a connection between the main portion of the tube and the chamber. By holding the tube with the hole upward, tipping it chamber upward, and then rotating the tube on its axis, any required portion of the air may be imprisoned in the chamber, to adapt the instrument to work in an atmosphere of any temperature, with a bubble of a normal size. Mr. Würdemann was the first to hermetically seal a tube containing the chamber, previous to which time it was closed by glass plates, bladder, and glue.

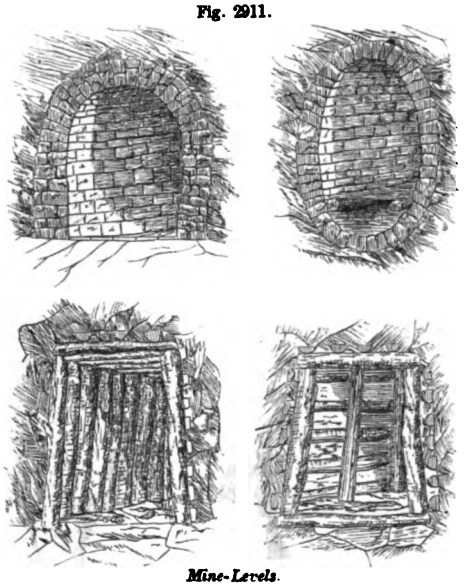
The most curious and delicate apparatus for leveling, in dividing and graduating instruments, and adapted for many other purposes, is the *contact-level* invented by Repsold, a celebrated instrument-maker of Hamburg. It is described on page 612, and room cannot be spared for duplicate descriptions.

2. (*Mining.*) *a.* A horizontal gallery or passage in a mine. The workings at different depths are

Fig. 2911.



Mine-Levels.

said to be at the different *levels*, — the 50 or 60 fathom level, and so on.

b. An adit or drift forming a drain for water.

A level which opens to the surface at the side of a valley is called a *day-level*, and forms a means of natural drainage without pumping.

A *drowned* or *blind level* is a drainage-gallery which has the form of an inverted siphon.

A *dip-head level* is the one which proceeds from the foot of the engine-shaft right and left, and from which the *rooms* proceed.

c. A gutter for water to run in.

Lev'el-er. 1. A billiard-table foot having a screw adjustment for hight, in order to level the table.

Fig. 2912.

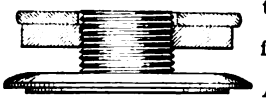

Table-Leveler.

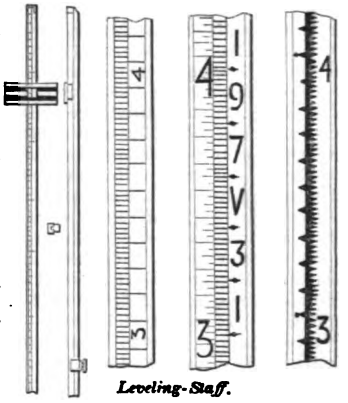
2. An earth-scraper for leveling a site.

Lev'el-ing-block. A leveling platform, consisting of large iron plates laid together and secured. The respective plates may be 8 or 10 feet long, 5 or 6 wide, and 6 inches thick. They are completely covered with holes, about 1½ inches in diameter and 4 or 5 inches apart from center to center. The mold of a given frame having been laid on the leveling-block, the figure of the molding edge is marked on it with chalk, and iron pins are stuck in the holes, so that when the iron rib is made to touch those pins it will have the proper form. In order the more easily to produce any required figure, the heads of the pins are furnished with eccentric disks or cams, by the shifting and turning of which the figure of the frame can be adjusted with great precision. Each disk has several center-holes, any one of which can be fitted on the pin.

The iron bar of the frame, having been raised to a bright orange heat in a reverberatory furnace, called a *reheating furnace*, is taken out by the smiths, laid on the *leveling-block*, and rapidly bent by means of tongs, hammers, mallets, and levers, so as to lie touching the heads of the pins.

Lev'el-ing-staff. An instrument, one form of which consists of two strips 6½ feet long, united by a longitudinal tenon and mortise so as to slide on each other and extend to a length of 12 feet. The divisions are in feet, inches, and fractions, and count from the bottom. A cross-piece or *vane* slides on the staff, and has an aperture to enable the staff graduations to be read. Inlaying with white wood gives more conspicuousness to the staff when viewed by the leveler.

Fig. 2913.



Leveling-Staff.

The staff is planted by an assistant, and the vane raised or lowered according to the signals of the engineer, until the center line of the vane coincides with the horizontal hair of the telescope. When the cross-wire of the vane is raised so high as to intersect 6 feet, it encounters a stop. If it be necessary to raise it higher, it is raised by elevating the front portion of the staff and the vane with it.

The staffs are graduated in various ways. Some have the duodecimal graduation ; others the feet divided into inches and tenths ; others the feet divided into hundredths, rejecting the inches.

Lev'el-ing-stand. (*Photography.*) An instrument used to support a glass plate in a horizontal position, so that it shall retain developing or other fluids upon its upper surface. Its usual form is a tripod, of suitable hight to stand in the developing-trough ; with three adjusting-screws by which the operation of leveling is accomplished.

Lev'el-lines. (*Shipbuilding.*) Lines representing the boundaries of sections drawn at different hights and parallel with the keel.

Water-lines are drawn parallel with the line of flotation or the true horizontal.

When the ship floats on "an even keel," the *level*-lines and *water*-lines coincide.

Le'ver. 1. (*Mechanics.*) A bar or other rigid instrument having a fixed point or a fulcrum, and

Digitized by Google

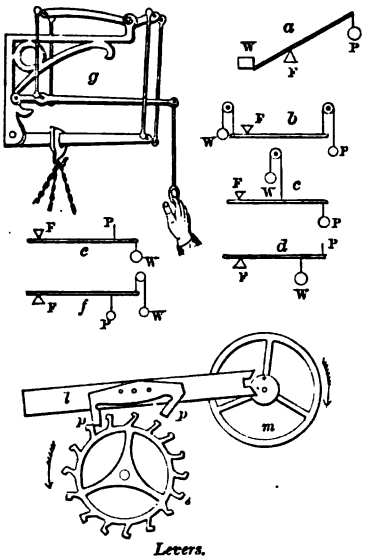
other points for the exercise of power and application to the object to be moved. There are three varieties, known as levers of the first, second, and third class, in which the fulcrum is respectively, —

1. Between the weight and the power, as at *a b*.
2. Opposite to the power, as at *c d*.
3. Opposite to the weight, as at *e f*.

g is a *compound lever* or system of levers, the basis of the ordinary weighing-machines.

In the illustration three levers are shown. When a system of this kind is in equilibrium, of course the ratio of the power to the load will be compounded of the ratios subsisting between the arms of each lever;

Fig. 2914.



Levers.

or, in other words, the power multiplied by the continued product of the alternate arms, commencing from the power, is equal to the weight multiplied by the continued product of the alternate arms, beginning from the weight.

2. (*Horology.*) A form of escapement.

In Fig. 2914, *l* is the *lever* having *pallets p p*; *s* is the *scape*-wheel, *m* the *balance*. The lever to which the pallets *p p* are attached turns upon a center-pin, so that the ends of the lever move backward and forward through small arcs, as the pallets are alternately released from the scape-wheel. One end of the lever has a little nick in it, which, as it passes backward and forward, catches a pin upon the balance and throws it right and left. As the lever, for example, moves to the left, one of the pallets catches a tooth of the scape-wheel, and stops the train; at the same time the balance is thrown round so that the pin passes out of the nick, and the balance swings free to the extent of the impulse; that is, it is *detached* from the lever. As it swings back under pressure of the hair-spring, the pin catches in the nick again, and, moving the lever back, unlocks the pallet, when instantly the other pallet is caught by another tooth, and the lever throws the balance the other way. The balance, therefore, in its isochronal swing, throwing the lever this way and that, and alternately locking and unlocking the teeth of the scape-wheel, determines the rate of movement of the train. This is known as the *patent lever*, *detached lever*, or *detached escapement*.

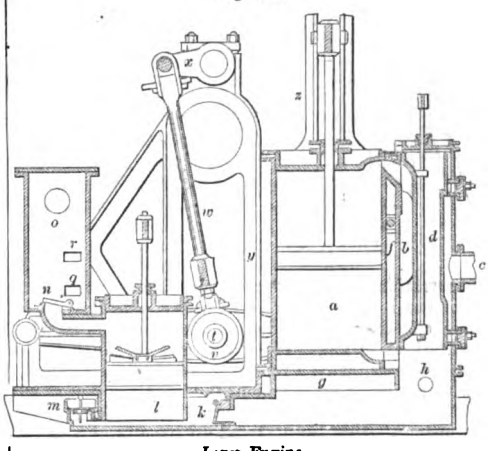
3. (*Surgical.*) An obstetric instrument, curved at its extremity, and having a fenestra. It is used in extracting the head of a child. A *vectis*. See also Obstetrical Forceps.

4. (*Dental.*) *a*. A tool for extracting stumps. *b*. A *turnkey*.

Le'ver-brace. A carpenter's hand-brace.

Le'ver-en'gine. A modification of the *side-beam engine*, in which the beams are levers of the second kind, the fulcrum being at one extremity of the lever

Fig. 2915.



Lever-Engine.

and the piston-rod connection at the other, the connecting-rod to the crank being joined to the beam at a point between the two.

a is the cylinder. *c*, the steam-pipe.

b, the slide-case or valve-chamber.

d, the long slide-valve, whose hollow forms the eduction-passage.

f, the way-shaft by which the valve is worked.

g, the condenser, cast in one piece with the bed-plate, and forming a pedestal to the cylinder.

h, the injection-pipe. *k*, the foot-valve.

l, the air-pump, inserted in a chamber formed in the bed-plate.

m, the blow-through valve. *n*, the delivery-valve.

o, the hot-well.

q r, the passages connected with the feed-pump, one forming the port for the supply of feed-water to the boiler, and the other the port by which the surplus is returned from the pump when the regulating valves or cocks of the feed-pipe to the boiler are closed. See Feed-pump.

t, the lever-beam gudgeon. *v*, the beam.

w, the connecting-rod. *x*, the crank.

y, the side-frame, firmly secured to the bed-plate, and to strong flanges cast on the cylinder.

z, the guides in which the cross-head moves.

Le'ver-es-cape'ment. The *lever*-escapement was invented by Mudge about 1780, and improved by Breguet of Paris and Roskell of Liverpool.

In its first form, the end of the *lever* had a segment-*rack* which engaged a *pinion* on the *arbor* of the *balance*. The improved form consisted in substituting a *fork* for the *rack*, making what is called the *detached lever*, patented by Roskell. (See Fig. 2914.) The lever vibrates on a center and carries the *pallets* (or *anchor*), and its forked end alternately engages with and is engaged by a ruby pin attached to a disk on the balance-arbor. The lever or fork, having the impulse given to it from the wheel, and then striking against the ruby pin, gives

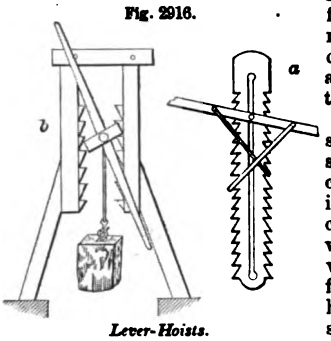
Digitized by Google

the motion to the balance from which it was disengaged, till brought back by the hair-spring; the ruby pin then strikes the fork and disengages the wheel, thus allowing it to go on.

This causes two distinct beats. See JEWEL.

Le'ver-hoist. (*Hoisting.*) Lagarouse's lever (*a*) is a contrivance for converting a reciprocating circular motion into a continuous rectilinear.

Fig. 2916.



Lever-Hoists.

The device is susceptible of several modifications. In the illustration, it consists of a lever reciprocating vertically on a fixed axis, and having a pair of stirrups which act alternately in the serrations on the respective sides of the rack. As one end of the lever is depressed, one stirrup is made effective, and a dog retains the rack at the obtained elevation. The other end of the lever is then depressed with a repetition of the result stated.

b is a similar arrangement for hoisting, described by the Marquis of Worcester in his "Century of Inventions," 1655, and stated to have been seen by him in the Arsenal of Venice. The cross-bar at the midlength of the lever has a fulcrum on alternate sides of the frame. The teeth are pivoted, and yield as the cross-bar presses against them from below, but afford a safe bearing when the bar rests upon them. The lever is oscillated and each sweep is effective. Several of our lever-jacks are substantially similar.

Le'ver-jack. A form of hoist having a *lever*, *post*, and pawl. See LIFTING-JACK.

Le'ver-ob-stet'ric. (*Surgical.*) *Vectis.* A spoon-shaped instrument employed in certain cases of protracted labor.

Le'ver-press. One of the simplest and most evident forms of pressing apparatus.

It assumes many forms: cider-presses, lard or tallow squeezers, cheese-presses, are constructed to obtain pressure by a lever, which is depressed by a suspended weight, as at *a*, by tackle or by a screw. See OIL, CHEESE, COTTON, HAY-BALING PRESS.

Hebert's oil-press *b* has a standing and a movable jaw with a lever by which the latter is oscillated. Depressions in the faces of the jaws hold the bag of olives, or other oil-producing fruit or seeds. The operator is worth his weight in stones or anything else and something more, as he can climb up to his perch.

c is a cheese-press having a screw for quick motion and a compound lever and suspended weight for continuous pressure. The nut of the screw is boxed in the short lever, which is of the second class. The long lever is of the same class.

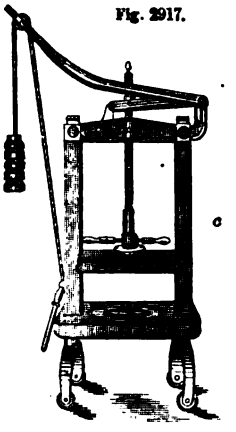
Le'ver-punch. A punch operated by the rolling motion of two cam-faced levers which are approached by a screw.

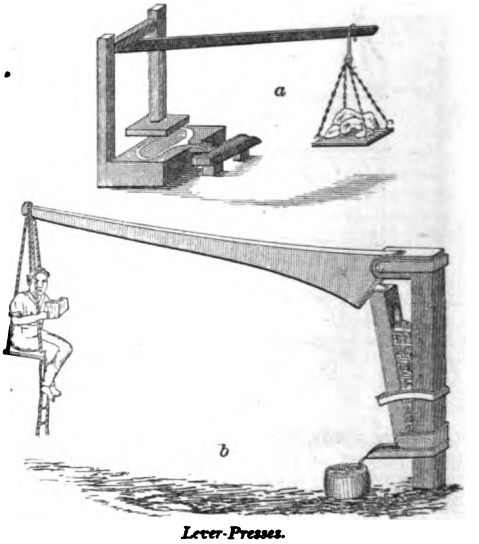
Le'ver-valve. A safety-valve kept in its seat by the pressure of a lever with an adjustable weight. The invention of Dr. Papin of Blois.

In locomotives a spring is used at the end of the lever instead of a weight; the pressure being regulated by a screw and indicated on a brass plate.

Under ordinary circumstances the valve-lever has a number of weights, which are added as occasion requires, or the weight is shifted in or out on the lever. See SAFETY-VALVE.

Fig. 2917.

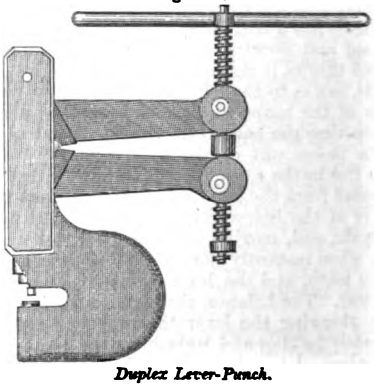




Lever-Presses.

Lev-i-ga'tion. A process of rubbing a moist material between two hard surfaces, as in grinding pigments and printer's ink.

Fig. 2918.



Duplex Lever-Punch.

Digitized by Google

Trituration is distinguished from levigation in the respect that the material in *trituration* is *dry;* in *levigation* it is *wet.*

When the process is by *muller* and *slab*, it is technically *porphyrization.*

Lew'is. 1. A device for lifting stones which was used many centuries back but received its name from a Frenchman who brought it to its present form. He was an architect on the works of Louis XIV., and gave it the name it bears in compliment to his master. It consists of two dovetail tenons, which are expanded by a key in a dovetail mortise in the stone, and shackled to the hoisting-chain. The dovetail pieces are first inserted and then forced apart by the middle key, so as to occupy the undercut portion of the mortise. All three are then shackled to the lifting-chain.

Fig. 2919.

Lewis.

The *lewis* was used by the ancient Romans, and the peculiar mortise marks are found in the stones of the Flavian amphitheater.

2. A kind of shears used in cropping woolen cloth.

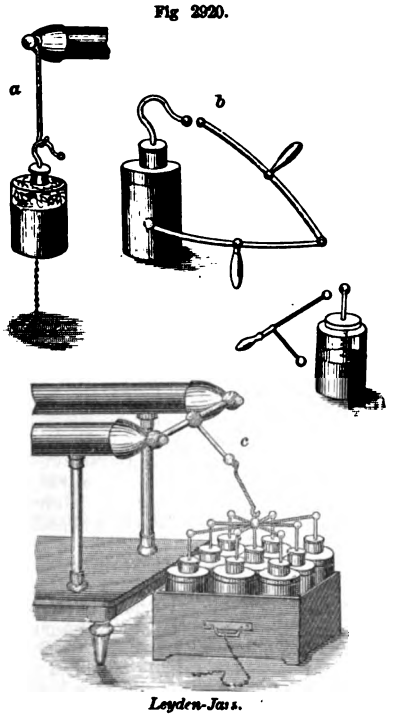
Lew'is-bolt. A wedge-shaped bolt secured in its socket by lead, and used as a *lewis* in lifting. See 7, Fig. 768.

Ley. A solution of an alkali. See LYE.

Ley'den-bat'ter-y. A number of Leyden-jars connected externally by resting on a metallic surface, and connected internally by rods and wires. See *c*, Fig. 2920.

Ley'den-jar. This is a glass jar coated both inside and out with tinfoil, for about four fifths of its hight. The mouth is closed by a cork, through which passes a metallic rod, terminating above in a knob and connected below with the inner coating, either by a chain or by pieces of tinfoil with which the jar is filled. If the inner coating be connected with an electrical machine, and the outer coating with the earth, the former acquires a positive and the latter a negative charge. On connecting them together, by means of a metallic discharger with non-conducting handles, as shown at *b*, a spark is obtained. *c* is a battery formed by connecting together in series all the outer and all the inner surfaces of several jars, so that the united force of the whole is concentrated in the act of discharging.

Fig 2920.



Leyden-Jars.

The principle of the Leyden-jar was discovered by Muschenbroeck at Leyden in 1745, hence its name. Von Kleist in Germany made the same discovery in the same year.

Gralath in Germany, 1746, contrived the electric battery by combining a series of jars; and finally Drs. Watson and Bevis, by covering the outside of the jar with tinfoil, brought it to the complete state in which we now have it.

The Leyden-jar is a condenser, its two coatings of tinfoil performing the parts of a collecting plate and a condensing plate.

Li-bel'la. 1. A small balance.

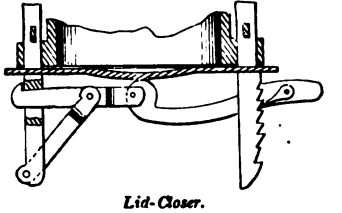
2. A LEVEL (which see).

Lick'er-in. (*Carding-machine.*) A drum with *cards* on its periphery presented at the throat of a carding-machine, so as to catch or *lick in* the cotton filaments as they are presented by the passage of the *lap* between the feed-rollers. See CARDING-MACHINE.

Lid. A cover, cap, or shutter, as of a box; or of the objective or eye-glass of an optical instrument; or of the charging end of a retort; or of the works or the face of a watch; of a hatchway, etc.

Lid-clos'er. 1. A clamp for the covers of gas-retorts, which, after charging, are closed with a luted joint to prevent escape of gas.

Fig. 2921.



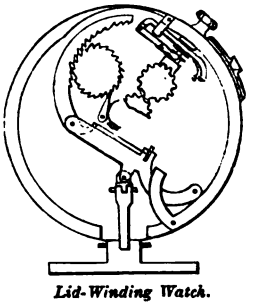
Lid-Closer.

2. Manholes of boilers and tanks are also closed with a bridge-piece and screw.

Lid-wind'ing Watch. One in which the opening of the lid, as occurring several times during the day, is made to wind up the going mechanism.

In the patent of Ramuz, 1868, the cover is connected to a lever which is operated by opening and closing the cover, and acts through a gimbal-joint upon a lever to which a curved ratchet-bar is pivoted. The curved ratchet-bar engages a ratchet-wheel, which communicates with the works so as to partially wind the same when the cover is opened to observe the time.

Fig. 2922.



Lid-Winding Watch.

Theurer's patent of 1866 seems to have been the first of the kind. Mozart's of 1873 may also be noticed.

Lie'ber-kühn. (*Optics.*) An annular reflector attached to the nose of the object-glass, and serving to illuminate an object by reflecting the rays which pass around the object through the slip on the stand.

Digitized by Google

Lierne. A branch rib introduced between the principal ribs of a groined arch, so as to form an ornamental pattern.

Life-boat. A boat with air-chambers or floats of cork, to give it great buoyancy and allow it to carry a load even when filled with water.

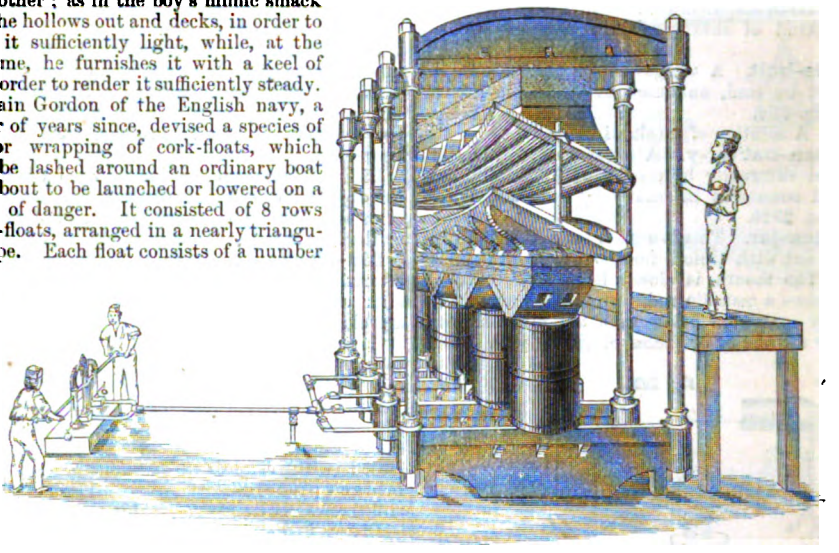
A common boat may be turned to a life-boat by increasing its flotative power. This may be done by bags of cork shavings, packages of cork, inflated bags, air-tight chambers, casks of air, etc. In cases of emergency, various means have been devised by ingenious men under the inspiration of danger or the force of professional training and habit. Brimmer's life-boat, used in England at the close of the last century, had kegs lashed inside the gunwale, bilge-keels, and a keel weighted with iron.

The belemnite, a calcareous fossil, the internal bone of an extinct family of cephalapods, seems to have united the principle of the *float* to that of the *sinker*, as we see it in some of our modern life-boats, which are steadied on their keel by one principle and preserved from foundering by the other; as in the boy's mimic smack which he hollows out and decks, in order to render it sufficiently light, while, at the same time, he furnishes it with a keel of lead in order to render it sufficiently steady.

Captain Gordon of the English navy, a number of years since, devised a species of buoy or wrapping of cork-floats, which might be lashed around an ordinary boat when about to be launched or lowered on a mission of danger. It consisted of 8 rows of cork-floats, arranged in a nearly triangular shape. Each float consists of a number of pieces of cork 1 foot long, 6 inches wide, and 1¼ inches thick, laid three thicknesses together, placed end to end till of the required length, and secured by split bamboo and lashings. The upper strake is the longest, say 9 feet long, and each succeeding strake is 1 foot shorter than the one above it. The strakes are secured together by 4 stout cords, which are seized together between each strake. The 8 combined strakes are so wrapped around an ordinary boat amidships, that the longest strake is just below the gunwale, and the shortest about the keel. The other side of the boat is similarly furnished. For a boat of large class a number of such floats may be provided. Two buoys like that described will displace 14⅜ cubic feet of water, and if added to a boat 28 feet long, and capable of containing 24 men, would leave a buoyancy of 718 pounds for their support.

Luken's life-boat, used in England about 1785, had projecting gunwales and double sides under

Fig. 2923.



Hydraulic Press.

them, serving as air-chambers, and air-tight chambers under the thwarts or rowers' seats. This arrangement increased the buoyancy and stability of the boat very much.

In 1789, Mr. Greathead of South Shields invented his boat, which proved so successful that it is said that previous to 1804 nearly 300 lives had been saved through its instrumentality near the mouth of the Tynemouth Haven.

This boat was about 30 feet in length by 10 in breadth, and 3½ feet deep, having a great sheer from the waist to the ends, which were both sharp and rose with a high curve. The gunwale projected several inches, and the sides were cased and lined with cork, secured by sheet-copper and copper nails. The quantity of cork employed was 700 pounds, the outside layer being 4 inches thick, extending along the whole side of the boat; the inside layer was somewhat thicker. The boat was rowed by ten oars, and an oar was employed for steering.

A two-wheeled sling-cart with arched axle was used for transporting the boat to the beach where it was desired to launch it. Mr. Greathead received a Parliamentary grant of £1,200 for his invention, and various rewards from different societies.

Francis's *metallic* life-boats are made between heavy dies, which swage one half the boat at a time by means of hydraulic pressure. The cut is sufficiently plain, requiring no lengthy description. The iron plates are corrugated to insure sufficient stiffness, the dies being grooved to fit each other and give the form to the plate pressed between them.

Water-tight compartments are distributed in different parts of the boat, so as not to be involved in any casualty which occurs in the staving of the boat.

The most important part of the construction consists in the longitudinal corrugations formed in the sheet-metal, by which the strength and stiffness are very much increased.

Francis, in his patent of 1839, describes metallic tubes laid longitudinally in the bottom of the boat, and divided by transverse partitions, which were connected by metallic bands or braces running crosswise of the boat, and which served as floats. Over these the flooring was laid. The framing and planking were laid much as in the ordinary manner. The

Digitized by Google

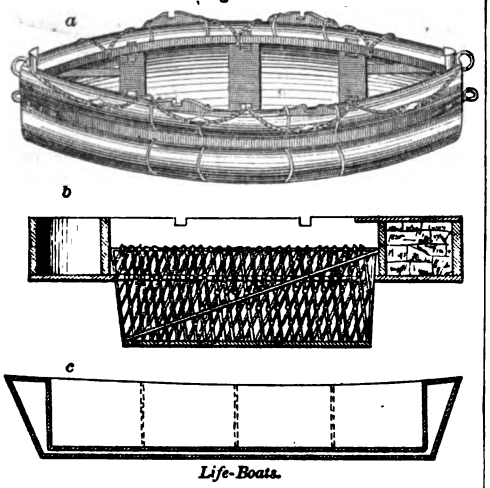
boat was partially decked over at the ends, forming compartments, and had transverse thwarts, between the two middle ones of which was a windlass for raising and lowering the anchor, which was suspended by a cable passing through a hole in the bottom; other holes were provided in the bottom for freeing the boat from water. The boat had a metallic keel.

Noble's life-boat (*a*, Fig. 2924) has a hold covered by a flexible air and water tight covering supported by and fastened to a sustaining frame. This cover may be made double, so as to be inflated and add to the buoyancy of the boat.

The hold is ventilated by a hollow mast with separated passages for the indraft of fresh and the exit of impure air.

In Fig. 2924, *b* represents a boat whose central part has no bottom. The top and bottom of the two end compartments are precisely alike, and act as floats. A net is suspended in the vacant middle space, so that, in whatever position the boat falls

Fig. 2924.



Life-Boats.

when launched, persons may be sustained by the suspended net and prevented from sinking; or, in case of capsizing while in the water, may clamber from one side to the other, the net falling to the lower side.

Tier's life and sporting boat (*c*, Fig. 2924) has an inner and outer shell, the space between them being decked over and divided by partitions. The inner shell forms the open space for the boatman.

Another form of boat consists of a cylinder terminating at each end in a conic frustum. It has hinged doors, and is moved through the water by a propeller driven by a shaft having an endless screw turned by gear-wheels worked by hand-crank in the interior of the boat.

A modification of this boat is also cylindrical, and the axes are journaled in a flotative frame, instead of making the cylinder separately buoyant. It is driven by an end propeller worked by a crank in the interior of the boat.

Beeching's life-boat, which received the prize of 100 guineas offered by the Duke of Northumberland in 1850, among nearly 300 competitors, is in form something like a whale-boat. It is about 36 feet in extreme length, 9½ feet in extreme breadth, and 3½ feet in depth. A cork-fender, about 7 inches square, runs around outside a few inches below the gunwale. Extra buoyancy is given by air-cases placed in all the vacant spaces of the boat. These, with the cork-fender, give a buoyancy or upward tendency of more than eight tons, counteracting to that extent the weight or downward tendency of the boat and its crew. For ballast, the boat is provided with water-tanks capable of containing about two tons, and there are pipes for emptying these tanks very quickly. If the boat be upset, the heavy iron keel and the filled water-tanks near the bottom, aided by the light air-cases near the top, tend to right it. It is rigged with a lug foresail and a mizzen. The draft of water, with thirty persons on board, is about two feet; the weight of the boat and its fittings is about three tons and a half, and the cost £250. It is capable of carrying seventy-five persons with safety.

The boat of the National Life-Boat Institution, England, is the invention of Mr. Peake, master shipwright of Devonport Dockyard. It is a strong boat, 30 feet long, 8 feet beam, and rowed by 8 to 12 oars, double-banked. It is nearly flat-bottomed, but the bow and stern rise 2 feet higher than the midship portion. Running along the upper part of each side, and occupying 4 feet at each end, are air-tight chambers, which impart sufficient buoyancy to float the boat and crew when the boat is filled with water. The iron keel weighs 800 pounds, and in connection with the curved shape of the boat infallibly rights the same when upset.

The boat has a false bottom above the water-line, and the space between the two is packed with cork and light wood. Passing through this light stuff are open-ended tubes, 6 inches in diameter, which carry down any water that is shipped by the boat.

The saving of life by life-boats in the British Islands, 1824–65, was 14,980 persons.

Life-buoy. (*Nautical.*) A buoy or float which is thrown overboard to sustain a person until assistance arrives.

It has various forms: —

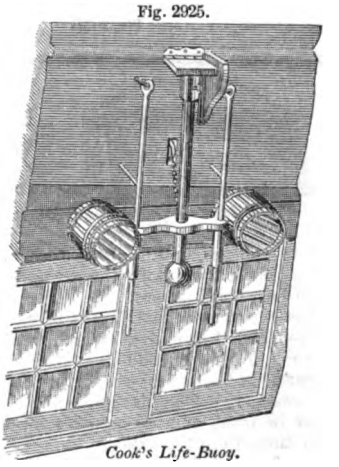
In one, each of the stools in the cabin has an air-tight tin case fastened beneath the seat.

2. An india-rubber belt capable of inflation.

3. A painted canvas case, of an annular shape, 31 inches in diameter, 6 inches wide, and 4 inches thick. It contains 12 pounds of cork, in thin layers.

Lieutenant Cook of the English navy invented a life-buoy which is provided on board all the vessels

Fig. 2925.



Cook's Life-Buoy.

of that service. It consists of two hollow copper vessels connected by a horizontal bar, through the

Digitized by Google

middle of which is fixed vertically a strong staff formed of a metallic tube, the upper extremity of which supports the fuse. The lower part of the staff has a balance-weight which drops out when the buoy falls, and maintains the staff upright in the water. The apparatus is kept suspended at the

Fig. 2926.

Life-Buoy.

quarter, is detached by a trigger, and the act of releasing it drops a gun-lock hammer and ignites the fuse, which blazes for a considerable time and attracts the man overboard while it directs the crew of the boat to the assistance of the person. It will support two persons.

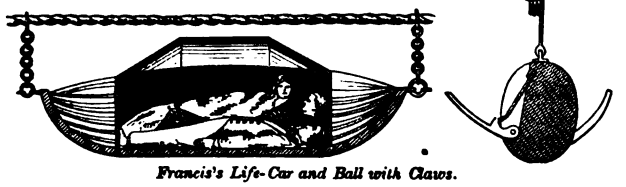
The life-buoy (Fig. 2926) is of similar character. The fuse composition is not extinguished by water.

Life-car. This is an apparatus used to communicate between a wreck and the shore, for the purpose of rescuing persons on board.

Francis's life-car resembles a boat, being a water-tight metallic shell, with a hatchway or cover, and is adapted to travel on ropes whose ends are connected to the ship and to the shore respectively. This connection is made by means of firing from a mortar a shot having a cord attached. The cord is so coiled upon a rack as to pay off freely as the shot is fired and falls beyond the vessel. The cord, being caught by those on board, is made the means for sending ashore a hawser or larger cord on which the life-car may be suspended.

The passengers, to the number of 3 or 4 at a time,

Fig. 2927.



Francis's Life-Car and Ball with Claws.

are inclosed in the car, and the trips are made by hauling on a rope attached to the car and grasped by parties on board and ashore.

One of these cars was the means of saving 200 passengers from the "Ayrshire," which went ashore at Long Branch, January, 1850.

Life-guard. (*Locomotive-engine.*) Safeguard, rail-guard, sweeper. The device embracing the brooms fixed in front of a locomotive for clearing small obstructions from the track.

Life-line. (*Nautical.*) *a.* A line stretched above a yard to enable seamen to stand thereon in manning yards.

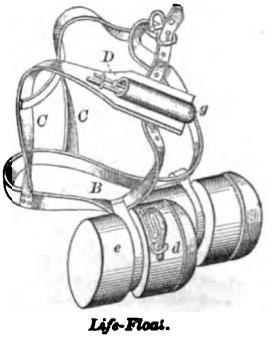
b. A line stretched from object to object on deck, for the men to grasp in bad weather and heavy sea.

c. A line attached at one end to a life-buoy and floating loosely, to assist a person in grasping it.

Life-pre-serv'er. 1. A device to enable a person to float in water in case of accident.

A cork-jacket or inflatable belt or waistcoat are ordinary devices for this purpose. Fig. 2928 shows a more pretentious life-preserver, constructed of two hollow drums or floats, with openings to receive valuable papers or documents, and with depressions *d* to receive the straps *e*. *B C* are the body-belt and shoulder-straps; the pocket *g* is intended to receive a signal-flag.

Fig. 2928.

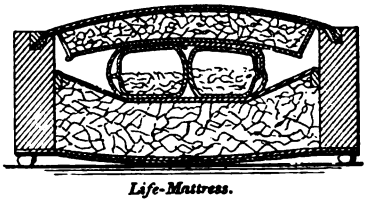


Life-Float.

Besides these articles for wear in an emergency are life-preserving mattresses, seats, berths, buckets, rafts, floats, and, in some cases, the general furniture and even doors of the cabins are specially made to subserve the purpose.

In Fig. 2929, two mattresses filled with cork have

Fig. 2929.



Life-Mattress.

between them an air-bag, confined in a fibrous sack to prevent rupture, the whole forming an elastic bed, which may be separated into several distinct life-preservers in accidents on water.

Life-preservers of cork date back to the time of the early Romans. The Roman messenger sent by Camillus to the Capitol, when besieged, swam the Tiber with a cork-jacket.

The *bamboo habit*, or Chinese life-preserver, consists of four pieces of bamboo, about a man's length, placed at right angles in parallel pairs, and tied firmly at the four corners, leaving an opening for the body, so that one pair of bamboos rests beneath the armpits.

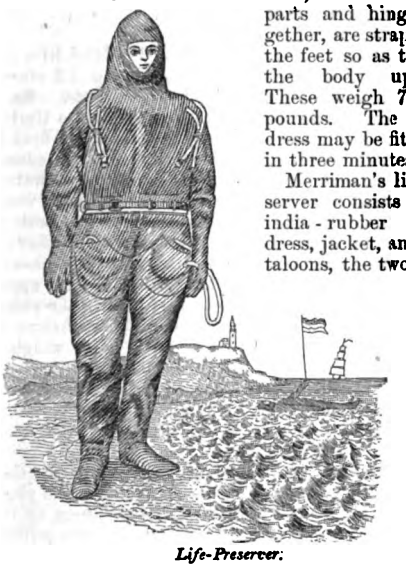
Captain Manby's apparatus is used in England to communicate with stranded or shipwrecked vessels. A shot thrown by a mortar has a line attached to it, and being thrown over the vessel the line is the means of hauling a rope on board, and thus communication is established with the shore, by hammock or cradle, which is arranged to traverse on the rope. (See LIFE-CAR.) Light-balls are thrown up and explode by fuse at a hight of 300 yards, so as to illuminate a large area and afford a view of the vessel in distress. The apparatus has been the means of saving several hundred lives. Captain Manby died

Digitized by Google

November 18, 1854, aged 89 years. For apparatus to enable a person to traverse foul air without inspiring it, see INHALER.

Stoner's life-preserver is of india-rubber, and made in one piece, the only openings being in the head-piece and at the wrists; the former is secured by bands passing over the top of the head and a flap under the chin. Suspenders pass over the shoulders from the waist, and an exterior waist-belt is buckled around the body. A cork jacket is buckled around the waist beneath the rubber garment, and is prevented from slipping by shoulder-straps. The lower parts of the dress are of thicker material than the upper, and leaden soles, made in two parts and hinged together, are strapped to the feet so as to keep the body upright. These weigh 7 to 8 pounds. The whole dress may be fitted on in three minutes.

Fig. 2930.



Life-Preserver.

Merriman's life-preserver consists of an india-rubber head-dress, jacket, and pantaloons, the two latter connected by a joint, around which is secured a belt to insure the junction being air-tight. It weighs about 14 pounds, and it is said can be inflated in 1½ minutes. The contained air serves to keep the body warm as well as to buoy it up. When in the water the bearer floats upon his back, having about one third of his body above the surface.

With each of these life-preservers is provided a case for holding water and provisions, and a small flag and staff to attract attention.

Ormsbee's life-preserver consists of inflatable sleeves, leggings, hip-bands, which may be worn with but little inconvenience when in positions of danger, or in learning to swim. Or they may be carried in the pocket.

2. A loaded stick or cane with a leaden head, used as a protection against assailants.

Lift. 1. (*Nautical.*) A rope stretching from a mast-head to the end of a yard, to *trim* it (*squaring*), or in *topping* (*yards apeak*).

A *topping-lift* is a rope which raises the after end of a boom.

2. A hoisting-machine. See list under HOISTING.

a. An elevator for goods or material in a furnace or mine. See ELEVATOR; FURNACE-HOIST; MAN-ENGINE, etc.

b. A *dumb-waiter*.

3. An exercising machine. See LIFTING-MACHINE.

4. The distance which an ore-stamp rises and falls.

5. (*Lathe.*) One of the several flats or grooves for the belt on the driving and cone wheels of a lathe. The varying diameters of the lifts are for changes of speed.

6. (*Shoemaking.*) One thickness or layer of leather in the *tap* which forms the heel of a boot.

7. (*Hydraulic Engineering.*) *a.* The amount by which a canal-boat is elevated in a lock. The difference in level between the upper and lower *pounds*.

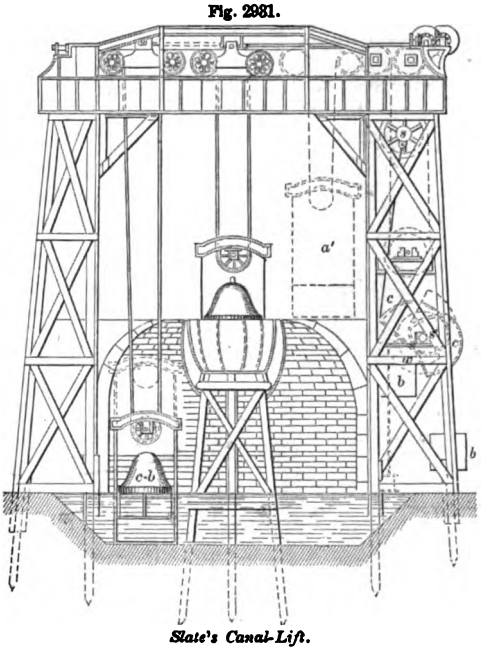
b. The rise of an undershot-wheel above the water-surface.

c. A substitute for canal-locks, the boats being lifted and lowered by machinery from level to level.

The boats are floated in water during transfer; gates and sluices in the main *line* are dispensed with; the boat is transferred from one level to another without loss of water.

The lower level is divided into two branches, which are carried along each side of the upper level

Fig. 2931.



Slate's Canal-Lift.

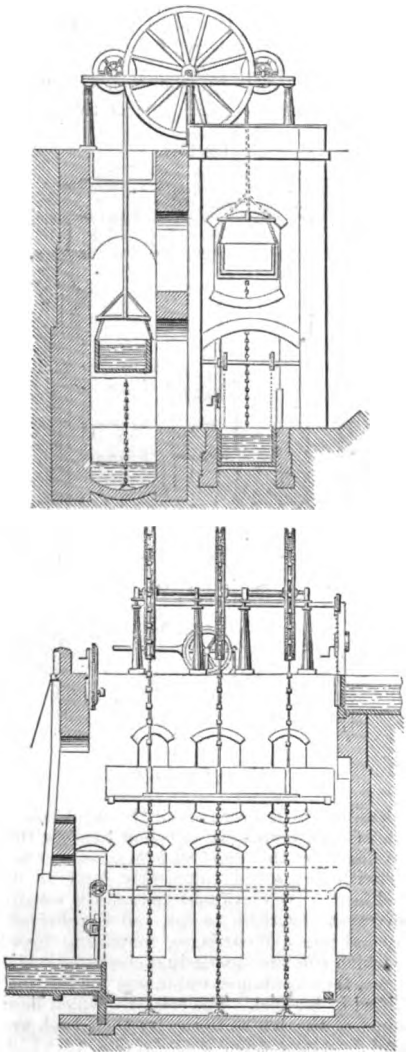
to a length a little over that of the canal-boat. The depth of each branch is sufficient to allow the boat *c-b* to float over the top of an iron caisson or tank *A*, filled with water and sufficiently large to float a loaded boat. An elevated framework is constructed to overarch the three basins, and is provided with transverse rails and carriages, containing the wheels over which run the suspending chains by which the caissons, their contained water, and the floating boat are lifted or lowered. The caissons, which lie in the bottoms of the basins to receive their load, are suspended by straps from cross-bearers, to which the suspending chains are connected. The chain which suspends one caisson and boat passes over drums on one carriage, and that which suspends the other caisson and boat passes over the drums on another carriage; the chain at each end of the lift being the same, passing in continuity over the different drums and around the long shaft at the side of the frame-work, so that, as the shaft revolves, the chain winds on one set of drums and unwinds from the other, one boat rising as the other descends.

The action is as follows: —

Digitized by Google

Two boats approaching the lift from contrary directions are floated over the sunken caissons in the lower and upper basins respectively. The load is uniform, whether the caisson contain a boat or otherwise, as the caisson is full of water in either case, and the boat displaces a weight of water exactly equal to its own weight. The shaft *s'* is rotated by steam or water power, and the chains wind on the cams *c c*, causing the upper shaft *s* to move down in the framework and draw the caissons with their

Fig. 2932.



Canal-Lift (Great Western Canal of England).

loads out of the water. The weight of the caisson is balanced by a weight *w*, which acts by a short or long leverage on the cams, according to the position of the caissons in or out of the water respectively. The buckets *b b* suspended from the shaft *s'* may be filled as required to assist the power in working the shaft.

The caissons being lifted out of the water, the upper caisson is moved on the railway across the canal, so as to be suspended over the lower basin, ready to descend.

When in this position the two caissons are in equilibrium, each suspended clear of the water, and over the lower basin, the upper one occupying the position in dotted lines *a'*. The equilibrium is then disturbed, by allowing some water to escape from the lower caisson, which thereupon rises, the positions of the respective caissons changing. The lately raised caisson is then moved over the upper basin by the traversing of its carriage on the railway above. Now all is in order for the descent of the caissons into the respective basins. The power is then applied to the shaft *s'* which allows the shaft *s* to rise, and the caissons are lowered simultaneously, the boats are floated over the ends of the caissons and resume their journeys.

On the Great Western Canal of England lifts are employed, 46 feet in hight and consisting of 2 chambers with a pier of masonry between them. Each chamber is of sufficient capacity to contain a timber cradle, in which the ascending or descending boat is placed. The cradle, when on the level of the canal, allows the boat to float into it by raising a water-tight gate at one end. The two cradles which work in the chambers, when full of water or when both or either of them contain a boat, balance each other on strong chains, which pass over 3 cast-iron wheels, and are so arranged that the water in the upper cradle is kept about 2 inches below that in the pond, which gives it a slight preponderance, sufficient to set the machinery in motion. The boats weigh 8 tons, and pass up or down the lift of 46 feet in about 3 minutes, consuming 2 tons only of water.

The upper view (Fig. 2932) is half a front view and half a transverse section of this lift. The lower view is a longitudinal section.

Lift-bridge. A bridge designed to lift to allow a canal-boat to pass, when the viaduct is but a short distance above the water-level. It is hung by the four corners to four chains, which pass over pulleys and have counterpoises at their other ends.

Lift'er. 1. (*Paper-making.*) A cast-iron wheel with buckets revolving in a case, lifting pulp from the reservoir or *pulp-chest*, and passing it to the trough, from whence it flows on to the traveling web. On the latter it is shaken, partially drained of its water, and is then delivered by the *coucher* to the first pair of pressing-rollers.

2. An elevator or hoisting-apparatus.

3. (*Steam-engine.*) The arm on a lifting-rod that raises the puppet-valve.

The upper portion of the figure (2933) is a top view of a Western steamboat engine, the lower portion is a side elevation on a somewhat enlarged scale. The lifter is shown in the middle, having curved surfaces at the points of contact with the valve-levers.

4. (*Founding.*) A tool used by a molder in elevating the *cope* from the *drag*.

5. *a.* A domestic tool for raising or adjusting the lids of a stove.

b. An implement for holding hot plates or dishes.

6. (*Surgical.*) A *levator* or lifting lever used in injuries to the cranium. It belongs to the trephine case. An *elevator*. The forms are four; known as the *common*, Louis', Petit's, the triploid.

7. A *cam* or *wiper* used in raising a stamper or beetle, or in depressing the tail of a tilt-hammer helve.

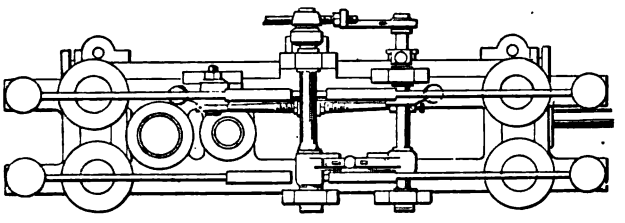
Lift-gate. A gate which lifts instead of swinging on a pintle, as, —

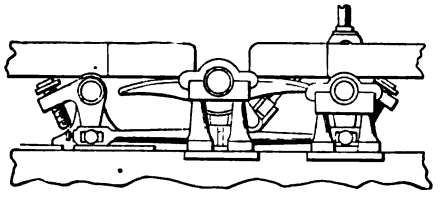
A portcullis.

A farm-gate counterbalanced, and rising in guides, like a sash.

Digitized by Google

Fig. 2933.



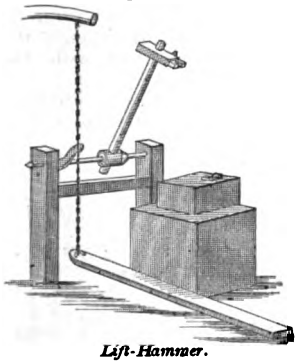


Valve-Lever Lifter.

A canal-lock, graving-dock, or sluice-gate which rises in vertical grooves in the walls.

Lift-ham'mer. The lift-hammer is a light form of tilt-hammer in which the hammer is raised by a spring and depressed by a treadle. When the hammer has a head of depressed contour, acting in concert with a counterpart tool on the anvil, it becomes a swage, the top and bottom tools answering to those of a *drop*. For this purpose, the vertical movement is preferable.

Fig. 2934.



Lift-Hammer.

The intention of the apparatus is to enable the blacksmith to dispense with an assistant, a *striker*, but it has not come into extensive use and is not likely to. It is asking too much of one man to attend to both operations skillfully.

Lift'ing-bar. 1. (*Knitting-machine.*) A horizontal rod or bar having a short intermittent vertical or nearly vertical reciprocation, and which at the proper moment operates to lift the *jacks*.

2. (*Weaving.*) The movable frame of a Jacquard loom in which the lifting-blades are fastened.

Lift'ing-blade. (*Weaving.*) An iron rule to receive the lifting-wires of a Jacquard loom when hoisted.

Lift'ing-bridge. The *lifting-bridge* is the simplest of all drawbridges, being merely a platform hinged to the bank, curb, or scarp at one end, the other being lifted by chains or cords worked by windlass or weights. It is used in crossing the canals in Holland, where the roadway is nearly on a level with the water.

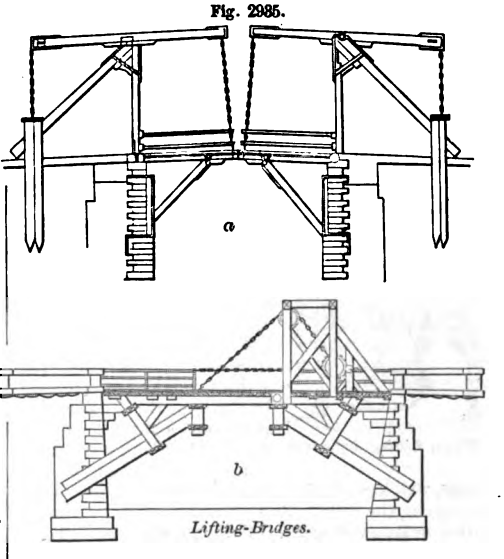
It is also used in fortifications.

The drawbridges (*a*) of Brussels were balanced by weights attached to chains passing over standards that stood immediately over the walls of the canal, and were braced and stayed by timbers and iron ties. The weight of the draws was borne by struts beneath, which were footed in set-offs in the faces of the masonry, and rested at their upper ends against jogs beneath the sill-timbers of the bridge.

Perronet, the great French engineer, 1708–94, was the chief engineer of the *Ponts et Chaussées* from 1747, and did more for the science of bridge-building than any of his contemporaries.

He contrived a drawbridge (*b*) which had a short middle draw to allow the masts of vessels to pass when the headway beneath the bridge was sufficient for the hulls of the vessels. This middle section is hinged to one portion of the bridge and lifted by a chain and winch.

Fig. 2935.

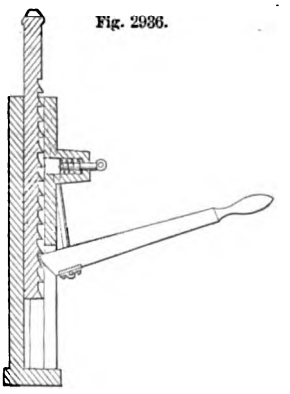


Lifting-Bridges.

Lift'ing-gear. (*Steam-engine.*) The apparatus for lifting a safety-valve from within a boiler. It consists of levers connected to the valve and to a screw worked by a handle outside the boiler. See LIFTER.

Lift'ing-jack. A hoisting-implement operated by a lever, a screw and lever, or by hydraulic pressure. The figures show forms of the *lever-jack*. For other varieties, see list under JACK.

Fig. 2936.



Lifting-Jack.

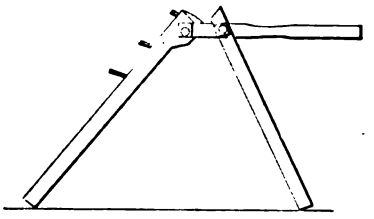
Fig. 2936 has a rack-bar raised by a lever pivoted in a strap, and the rack is sustained by a sliding spring catch.

In Fig. 2937, the upper ends of the legs are connected by a lever, by whose depression they are erected and the wagon-axle raised.

In Fig. 2938, the fulcrum-pin of the lever rests in rounded notches in the standard, and is held down by an extension pawl which is pivoted to the stand-

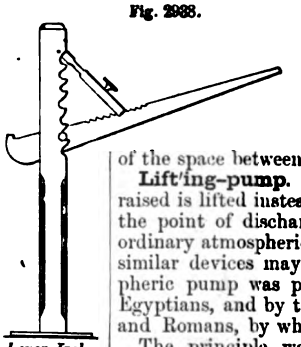
Digitized by Google

Fig. 2937.



Lifting-Jack.

Fig. 2938.



Lever-Jack.

ard and engages a ratchet on the upper side of the lever.

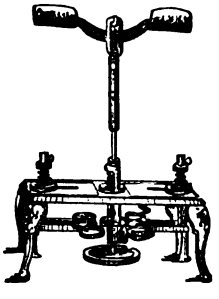
Lift'ing-ma-chine'. An exercising-machine belonging to the furnishing of a gymnasium, in which a weight is so disposed with handles or straps for the hands, hips, or shoulders, that a person may conveniently try his strength, and improve by persistent trying at gradually increasing weights. Weights or springs are used, sometimes in connection with a dynamometer, to indicate the force exerted.

Fig. 2939.

Weight Lifting-Apparatus.

Fig. 2939 shows Butler's standard health-lift, giving a dead-weight lift softened by spring-action. The platform on which a person stands in lifting rests upon ten volute springs on the frame, the legs of the frame resting also on volute springs on the floor. Rubber cushions and cartilages soften every movement. Through the center of the machine passes an upright rod, having at its upper end a stirrup through which the handle is passed transversely, while at the lower extremity, beneath the platform, is a disk to receive the weights, of from one to fifty pounds each. The handle passes through springs at the platform level, which sustain the weight and gradually release it as it is lifted clear. Weights to the amount of 600 pounds are provided. The machine occupies a space of 26 × 32 inches on the floor; 26 inches to the top of the platform. The person stands a-straddle of the handle, and lifts with one hand in front and the other in the rear.

Fig. 2940.



Spring Lifting-Machine.

Fig. 2940 is a machine in which graduated springs are substituted for weights.

Many other forms of exercising-machines are used, some for the bedridden, some specially adapted for victims of spine disease, some for general exercise of the muscles to improve the tone of the system. See EXERCISING-MACHINE.

Lift'ing-piece. (*Horology.*) A lever having a tooth which engages in notches in the *count-wheel* to restrain the striking. The *count-wheel* has 78 divisions, and notches are cut in it at the successive distances of 1, 2, 3, 4, etc., of the divisions. The lifting-piece being raised by a pin or a snail on one of the hour-wheels, the tooth of the lifting-piece rests on the rim of the count-wheel until the prescribed number of blows is given, according to the length of the space between the notches.

Lift'ing-pump. One by which the liquid to be raised is lifted instead of forced from its receptacle to the point of discharge. To this class belongs the ordinary atmospheric pump. The chain-pump and similar devices may also be included. The atmospheric pump was probably known to the ancient Egyptians, and by them handed down to the Greeks and Romans, by whom it was little used.

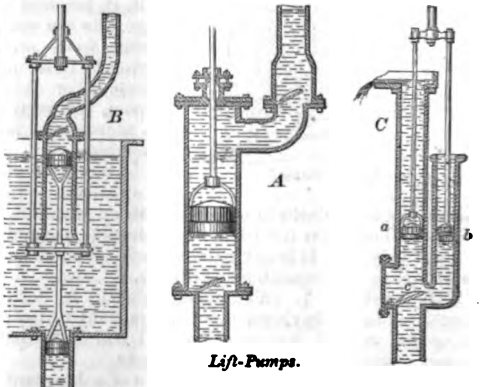
The principle was explained by Torricelli, the pupil of Galileo, whose attention, as well as that of his master, was drawn to the matter by the unsuccessful efforts of the Florentine pump-makers to raise water by its means to a hight much over 30 feet. In fact, at elevations above the sea-level, it can only be lifted to a hight in feet about equal to the number of inches at which the mercury in the barometer stands; one inch of mercury corresponding to about 13 inches of water. See LIFT-PUMP.

Lift'ing-tongs. The tongs with concave jaws used in grasping crucibles. See CRUCIBLE-TONGS.

Lift-pump. *A* (Fig. 2941) shows one form of modern lifting-pump. The head of the pump is closed, and the water may be lifted through the side tube to any elevation consistent with the strength of the tube.

B is a double-piston pump adapted to situations where the pump cannot be conveniently inserted in the reservoir. The piston of the atmospheric pump is directly under that of the lifting-pump, and works in a cylinder attached to the bottom of the cistern. Each is attached to the same rod and worked by the same frame.

Fig. 2941.



Lift-Pumps.

In *C* two pistons *a b* are placed in two cylinders, side by side, and are operated simultaneously by attachment to a cross-head, both drawing up the water at the same time. The downward movement, as it closes the valve *c*, forces the water upward through the cylinder *a*, maintaining a continuous discharge.

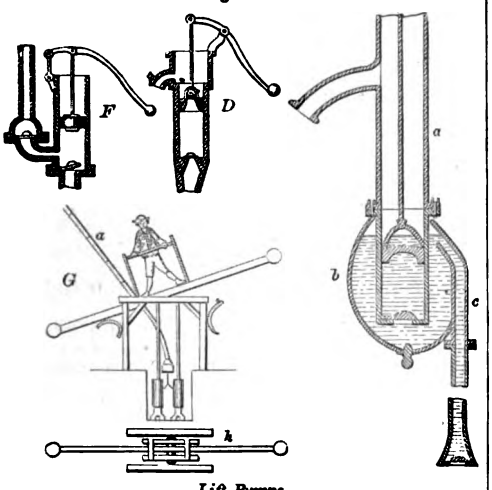
D (Fig. 2942) is an atmospheric pump. The upper valve is of peculiar construction.

F is a solid-piston pump, which lifts the water to the barrel, and on its downward stroke forces water up the pipe.

Digitized by Google

G is a double-cylinder balance-beam pump. The pistons are alternately raised and lowered by a man

Fig. 2942.

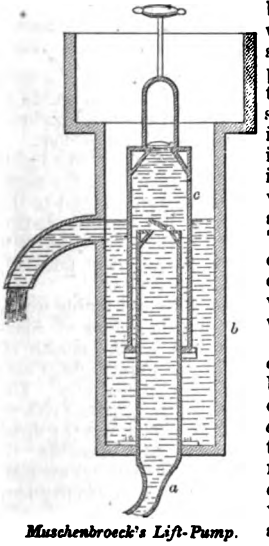


Lift-Pumps.

throwing his weight alternately on either side of the beam, and discharge the contents of the cylinders through the pipe *a*. *h* is a plan of the beam and its frame, on which the man stands.

In Lecorche's pump (to the right), the cylinder *a* is surrounded by an air-tight vessel *b*, which, being originally filled with water to a hight sufficient to cover the piston, always keeps the valve wet. Each stroke creates a vacuum in the vessel *b*, causing the water to rise in the cylinders *a c*, whose valves are lifted at the same time. This arrangement also obviates the shock caused by the water when the piston is worked rapidly.

Fig 2943.



Muschenbroeck's Lift-Pump.

Fig. 2943 is a pump described by Muschenbroeck. The upper end of the suction-pipe *a* enters a small cistern *b*, and is surrounded by a cylinder *c*, the lower part of which fits closely around it. The valves of both open upwardly. The upward movement of the cylinder *c* causes a vacuum in both it and *a*, which become filled with water, the downward movement of *c* causing the water therein to overflow into the cistern *b*, whence it is discharged.

Lift'ing-rod. (*Steam-engine.*) A rod receiving motion from the rock-shaft, and imparting motion to the *lifter* of the puppet-valve.

Lift'ing-screw. A form of hoist in which a screw is used. See JACK-SCREW.

Lift'ing-set. The series of pumps by which water is raised from the bottom of a mine by successive lifts. See CORNISH ENGINE.

Lift'ing-wires. (*Weaving.*) The wires by which the warp-threads are raised and lowered to produce the pattern in a Jacquard apparatus.

Lift-latch Lock. (*Locksmithing.*) A lock in which the latch is pivoted and *lifted* free of the keeper, passing through a notch in the box, instead of being simply retracted.

Lift-lock. (*Engineering.*) A canal-lock, in which a boat is *lifted* by the introduction of water, so as to raise it to the upper level. See LIFT, 7.

Lift-tent'er. 1. A contrivance adopted in European windmills for regulating the distance apart of the mill-stones, according to the speed of the vanes. It is of the nature of the steam-governor, having suspended balls which fly out by accession of speed, and thus act upon the *bridge-tree* by which the runner is supported.

2. A ball-governor arrangement to regulate the speed of a windmill's vanes. This use of the contrivance preceded that of its application to the steam-engine.

Lift-wall. (*Hydraulic Engineering.*) The wall at the head of a canal-lock chamber. See CANAL-LOCK.

Lift Wa'ter-wheel. 1. An under-shot wheel.

2. A water-wheel whose gudgeons and bearings may be raised or lowered to adapt it to varying hights of water supply.

Lig'a-ting-for'ceps. A pair of grasping fingers protruding from a sleeve and closed by retraction into the sleeve. Other forms are used, the specific construction depending upon the nature of the operation and the size of the available opening for its application.

Lig'a-ture. 1. (*Printing.*) Two or more letters cast on one shank; as ff, ffi, etc.

This was formerly very common, and was carried to an excess by Earl Stanhope, who called them *logotypes*.

They are now confined to some diphthongs and the &, which is derived from &, the *logotype* of *et*.

2. (*Surgical.*) *a.* A thread to tie arteries or veins.

b. A wire cord or thread used in removing tumors, etc. See ECRASEUR.

c. The bandage used for phlebotomy.

Galen recommends silk thread for tying blood-vessels in surgical operations.

The ligation of the femoral artery was first performed by Hunter, about 1785.

That of the external iliac by Abernethy, 1796.

The internal iliac by Alexander Stevens, in 1812.

The common iliac successfully by Dr. Valentine Mott, in 1827.

The common carotid by Sir Astley Cooper (successfully), in 1808.

The innominata by Mott in 1818, and successfully by Dr. J. W. Smythe in 1864.

"Ambrose Paré, born at Laval, in France, in 1509, was a member of the fraternity of barber-surgeons; but, such was the reputation he acquired as an operator, he was made surgeon to four successive sovereigns of France, and, among others, to the weak and cruel Charles IX., by whom, however, although Paré was a Huguenot, his life was saved on the terrible night of the massacre of St. Bartholomew, by detaining him in the royal chamber until morning. With Paré, who lived little more than 300 years ago, we may commence to date the achievements and triumphs of modern surgery. Hitherto, after amputations, the bleeding-vessels had generally been secured by searing them with cauterizing irons, or by dipping the end of the stump in boiling oil or molten lead. Paré revived the ligature, which, although it had

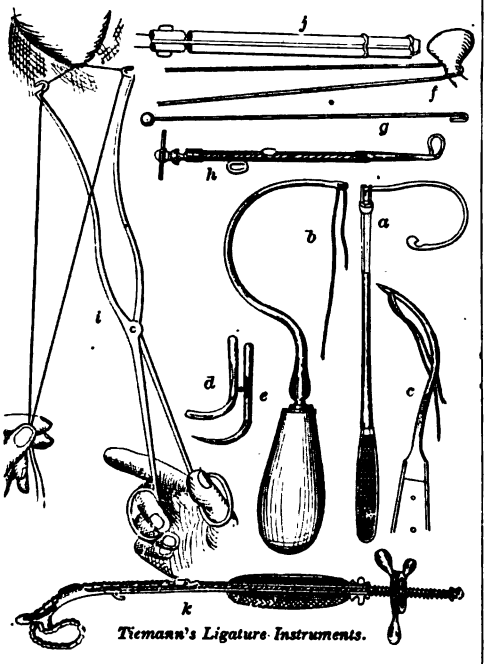
Digitized by Google

been suggested, and probably adopted in a few cases several centuries before, had been forgotten or abandoned by his immediate predecessors. Such was the mortality under the old process of securing the vessels, that Guy de Chauliac declared it was better to let the limb drop off than to amputate it with the knife; and he advised ligating firmly at the nearest joint, and thus to cause gangrene and sloughing of the limb below. Since Paré wrote, great improvements have been made in the application of the ligature, and its usefulness has been greatly extended; especially is it proper to mention its application for the reduction of vascular tumors, including elephantiasis, for the relief of epilepsy, and for various other maladies in which it is known that organs are suffering from an excess of blood; but the greatest achievements of the ligature have been in the cure of aneurisms." — F. H. HAMILTON, M. D.

The ligature occasions obliterations or adhesion of the arterial parietes by cutting through the middle and internal coats, the adhesion being favored by the formation of a coagulum, which acts in some degree as a barrier against the impulse of the blood, and subsequently disappears by absorption.

Lig'a-ture-car'ri-er. A surgical instrument with a bent stem for passing a ligature around an artery

Fig. 2944.



Tiemann's Ligature Instruments.

which is to be ligated, a bone which is to be divided by a chain-saw, or other object which is to be cut.

In the absence of special instruments therefor, the duty is performed by a curved needle carrying a thread.

a, Fig. 2944, is Post's chain-saw carrier. *b* is Tiemann's instrument to carry ligature for chain-saw. *c* is an aneurism needle. *d e* are Mott's aneurism needles. *f g h* are Van Buren's artery-ligating instruments. *i* is Carrol's knot-tyer. *j* is Gooche's double cannula for uterine polypus. *k* is Charriere's lengthened chain-ecraseur.

Lig'a-ture-ty'er. An instrument to carry flax or silk thread, or silver wire, for tying off arteries, aneurisms, tumors, polypi, or piles, etc. See Fig. 2944, LIGATURE-CARRIER.

In Carrol's ligature-tyer (*i*, Fig. 2944) the ligature, being held by the blunt hooks, which are at right angles to the branches, is readily passed around the tumor, and the instrument withdrawn; a single knot is tied, which is easily slid up to the tumor and tightened, the instrument operating after the manner of a glove-stretcher. A second knot is tied in the same manner, and with almost as great facility and rapidity as could be achieved by the fingers in an accessible situation. It might also be of service to tighten a ligature upon a vessel at the bottom of a deep wound where the fingers cannot be readily used.

When the artery alone is tied, the ligature is said to be *immediate*. When any of the surrounding parts are included, it is said to be *mediate*.

Lig'ger. A line with a float and bait laid for night fishing.

Light. 1. An illuminating body, as a burning candle, lamp, etc. A lime, calcium, electric, Drummond, oxyhydrogen, etc., light. See list, *infra*.

A calculation of the respective values and costs of different lighting materials is as follows: —

Six mold candles weighing one pound will burn forty hours, if lighted in succession. One gallon of sperm-oil, burnt during the same time, will give a light equal to fifteen of such candles. Twelve cubic feet of gas will give a light equal to the six candles during the same time.

Prices vary at times, and that of gas varies from $1.70 to $7.00 for 1,000 feet in different parts of the United States, but at the prices annexed the following will be a comparative statement for forty hours' burning of an equal power: —

15 pounds of sperm-candles, at 20 cents	$3.00
1 gallon sperm-oil, at $2.00 . .	2.00
180 cubic feet of gas, at $3.00 . . .	.54

2. (*Nautical.*) A burning lamp, cluster of lamps, or beacon fire, serving as a warning and guide to mariners arriving off a coast or in the neighborhood of dangerous rocks or shoals. See LIGHTHOUSE.

It is usually displayed from a tower, called a lighthouse, and has several variations, incident to the mode of production or emission and direction, and to the visible characteristics by which the mariner distinguishes one light from another when arriving off a coast, so as to ascertain his geographical position, and his bearings as to his port or course.

In early times the light was a fire of burning wood. Such were the lights of the famous Pharos of Alexandria, and the Tour de Corduan at the mouth of the Garonne. In 1812, the Lizard Point light, Cornwall, England, was maintained with coal fires. The same may be said of the Isle of May light, Frith of Forth, Scotland, in 1816. This, in fact, was the usual light at that time in positions readily accessible.

The Eddystone light first consisted of tallow candles stuck in a hoop, and afterwards of twenty-four wax candles.

The *Argand lamp*, invented in 1784, and bearing the name of its distinguished inventor, rendered a better light possible. See ARGAND.

It was introduced into the Tour de Corduan soon after its invention, and associated with paraboloid reflectors in a revolving frame. This is the *catoptric* system, invented by Tulère of the French Royal Engineers of Bridges and Roads. See CATOPTRIC LIGHT.

Argand burners and paraboloid reflectors were substituted for wax candles in the Eddystone lighthouse in 1807.

In the *dioptric* light the beams are transmitted through lenses, instead of being reflected by mirrors.

Digitized by Google

Lenses were adopted in some lighthouses about 1752–59, but owing to the imperfections of glass and manufacture, they were not in much favor till the improvements of Fresnel about 1810. See DIOPTRIC LIGHT.

The *cata-dioptric light* is a combination of the two, as its name indicates. See CATA-DIOPTRIC LIGHT.

The *oxyhydrogen light* and the *voltaic light* from carbon points have been proposed, owing to their brilliancy. See ELECTRIC LIGHT.

The term *leading-light* indicates such a disposition of two lights on distinct towers as to indicate a course, a channel, or a danger. See LEADING-LIGHT.

A *floating* light is one at the mast-head of a vessel moored on a spit or shoal where no adequate foundation exists for a permanent structure. See FLOATING-LIGHT.

The characters of the light furnished to the mariner are varied, so that when he comes in sight of a given light he may tell by its color or behavior where he is.

These distinctive lights are thus enumerated: —

Fixed.	*Flashing.*
Revolving.	*Colored.*
Intermittent.	*Double.*

The *fixed* light gives a constant and steady radiance.

The *revolving* light is produced by the revolution of a frame with three or four sides, having reflectors grouped on each side with their axes parallel. The frame rotates once in a minute, or once in two minutes, as may be required, the light fluctuating between full strength and total darkness, the changes being gradual. See REVOLVING-LIGHT.

The *intermittent* light is produced by the perpendicular motion of circular shades in front of the reflectors, by which the light is alternately hidden and displayed. The alternations of light and darkness are sudden, and occur at intervals of about thirty seconds.

The *flashing* light is produced by a revolving frame, the mirrors of which are arranged on 8 sides. The reflectors on each side are arranged with their rims or faces in one vertical plane, and their axes in a line inclined to the perpendicular. This disposition, in connection with the rate of motion, gives a flash of light every 5 seconds, alternating with comparative dimness. There is no eclipse, but a pulsating effect; bright and dim, bright and dim.

The *colored* light may be of various colors, but for important situations and distant view *red* is alone used. A variety is given in revolving lights by alternating *red* with *two whites* or *one white*, or *two reds* with *one white*. Also by associating a *red* and a *white* light in a *double light*.

Colored media absorb so much light as to detract from their usefulness. They have been generally discarded in French lighthouses.

The *double* light is exhibited from 2 towers, which may be of equal hight, but usually differ in hight. It is used as another mode of marking a particular headland, as at the Lizard Point and Calf of Man, in British waters. It also affords a *leading* light, as the conjunction of the two lights in one line is made to indicate a course or a warning. See DOUBLE LIGHT.

These lights may be variously combined. The catoptric admits of the following variety: —

1. Fixed.
2. Revolving white.
3. Revolving red and white.
4. Revolving red with two whites.
5. Revolving white with two reds.
6. Flashing.
7. Intermittent.
8. Double fixed.
9. Double revolving.

The variations in the dioptric lights are *fixed* and *revolving;* the main distinctions of the latter being founded upon the time between flashes.

According to the British and French regulations, vessels, between sunset and sunrise, are ordered to carry lights as follows: —

A *green* lamp on the starboard side and a *red* light on the port side, visible throughout an arc of 10 points from right ahead to 2 points abaft the beam. An inboard screen prevents the light from being seen from the opposite side. Steamships, in addition, carry a white light at the foremast head, visible through an arc of 20 points, extending between points 2 points abaft the beam on each side.

Steam vessels towing other vessels to carry *two* foremast head-lights, in addition to the side lamps.

Vessels at anchor to carry a white light, visible all round, and not exceeding 20 feet above the hull.

3. (*Shipbuilding.*) An opening in the deck or side of a vessel, as *deck-light*, etc.

A *side-light* is also known as a *light-port*. The water-tight shutter by which it is protected in stormy weather is known as a *dead-light*.

4. A pane of glass.

Light-ball. (*Ordnance.*) The ordinary light-ball, which has been in military use for centuries, consists of a canvas sack of elongated shape, filled with a combustible and illuminating composition. It is used for lighting up works in sieges, and also for discovering the position of an enemy; in the latter case it is charged with a shell to prevent its being approached, and is fired from a piece of ordnance. As from its position on the ground it can illuminate but a limited area, parachute light-balls have been proposed. That of Sir William Congreve was to be attached to a rocket. General Boxer's light-ball was adopted into the British service in 1850. It consists of a mass of sulphur, saltpeter, and red orpiment, inclosed in a hemispherical case of tinned iron, which is attached by chains and cords to a large calico parachute that is compressed into a similar hemispherical casing, the two forming a sphere, having an annular depression surrounding it. A second tinned-iron case fits over the first, and has a fuse communicating with a train of quickmatch in the annular groove before mentioned, and also with the bursting charge. This projectile is fired from a mortar.

Light-bar'rel. An empty barrel, pierced with holes and filled with tarred shavings, to light up a breach.

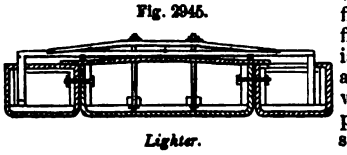
Light-boat. A vessel carrying a warning light. See LIGHT-SHIP.

Light'en-ing. The peculiar brightness of silver at the moment when the maximum of purity is attained.

"The moment when the oxidation of the lead ceases, and when consequently the cupellation is finished, is marked by a peculiar appearance called lightening. During the whole period of oxidation, the metallic bath appears more brilliant than the walls of the furnace. Its temperature is in fact higher; for not only does it share in the heat of the furnace, but its temperature is also raised by the heat disengaged by the chemical combination of the lead with the oxygen. When, however, the lead is completely oxidized, the second source of heat no longer exists; the disk of metallic silver soon sinks down to the temperature of the furnace, and, instead of being as brilliant as before, it becomes dull. On the other hand, at the moment when the last traces of lead oxidize, there is on the surface of the metallic bath only a thin pellicle of fused litharge; this quickly becomes thinner and thinner, and presents in rapid succession the colors of thin plates or of the soap-bubble, then becomes torn up like a veil, and discloses the surface of the silver beneath." — REGNAULT.

This development of purity and capacity for perfect reflection in the silver from which all dross has been removed, is a favorite simile in the Bible, where the "refiner and purifier of silver" is represented as "sitting" watching the process, whose success is evidenced by the perfect reflection of the Master's face. Fulguration.

Fig. 2945.



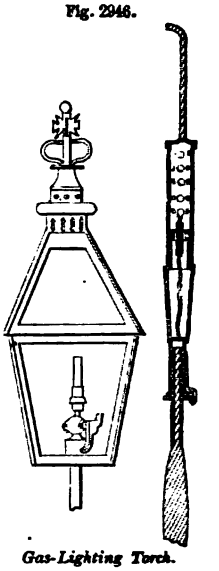
Lighter.

Light'er. 1. (*Vessel.*) *a.* A barge for transporting merchandise and stores, on rivers and canals, over bars, and to and from vessels moored in a stream, or where they cannot be laden from or discharged on to a wharf or pier alongside.

b. A craft for taking a part of the burden of a vessel to assist it over shoal places. In the example, the lighters are attached to the boat's sides by transverse braced beams and bolts, extending through the sides, and act as *camels*.

2. A torch or electrophorus for lighting gas. An *allumette* for lighting lamps or candles. The example is a torch for street-lamps. The lamp-frame has a small trap-door at the bottom, through which the hook is introduced to turn the cock by its bell-crank lever. The torch lamp is protected by a cylinder, whose perforations are large enough to allow passage of inflamed gas.

Fig. 2946.



Gas-Lighting Torch.

Light'er-screw. (*Milling.*) A screw for adjusting the relative distances of the *runner* and *bed-stone*. The *runner* rests on a *spindle*, which is supported on a *bridge-tree*; the *lighter-screw* raises and lowers the latter. See GRINDING-MILL.

Light'house. The ancient word *Pharos*, a light-house, is probably derived from *Phrah*, the Egyptian god personating the sun.

Pthah, in the Egyptian mythology, was the embodiment of stability. The essential portion of the figure strikingly resembles the figure of the Eddystone lighthouse, which Smeaton derived from the observation of the trunk of a tree. The figure (*a*, Fig. 2947) is shown divested of the arms and head-dress of the god whom it shrouds.

The most celebrated lighthouse of antiquity is that erected on the island of Pharos, harbor of Alexandria. It was built by the orders of Ptolemy Soter, by the architect Sostratus, and finished under Ptolemy Philadelphus, 280 B. C. The wonderful energy of Alexander's mind seems to have comprehended all at a glance. He visited the little town of Rhacotis, saw his superb city as by a dream of enchantment, his Macedonian mantle covering the ground between the river and Lake Mareotis. He gave his orders to Dinocrates, the architect of the temple of Diana at Ephesus, settled the main details of the plan, and never saw the place again.

The Pharos was 450 feet high, and the light was visible at a distance of 42 miles (300 stadia, *Josephus*). It was built of white marble, and cost 800 talents, $825,500, if the talents were Attic. It was formed in several stories, decreasing in dimensions towards the top, where fires were lighted in cressets. The ground-plan was hexagonal, the sides alternately concave and convex; each a stadium in length; the 2d and 3d stories were of the same form; the 4th was square, with a round tower at each angle; the 5th circular, continued to the top, to which a winding staircase conducted. The whole was surrounded by a sea-wall, and was on the right hand of the harbor-entrance, opposite the promontory of Lochias, on which was the royal palace.

Digitized by Google

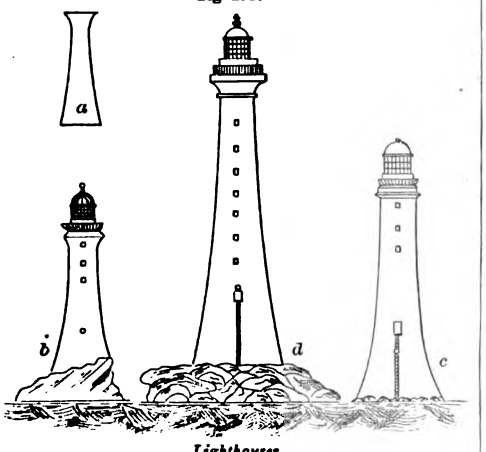
Fires were kept lighted on the summit, and it was inscribed, "King Ptolemy to the gods, the saviors, for the benefit of sailors." Sostratus carved his own name beneath and filled it with mortar, upon which Ptolemy's name was inscribed. In process of time the mortar scaled off and brought the name of the architect to the surface. The tower fell A. D. 1303.

Other ancient lighthouses were situated at Messina, Ostea, Ravenna, Puteoli, Caprea, Rhodes, Dover, the Thracian Bosphorus. The light in each was obtained by fires.

During the Saxon rule in England, beacons were erected to direct navigation, and persons were appointed to keep them in order. The expense was defrayed by the county. Pitch boxes were made use of in the reign of Edward III.

The Eddystone lighthouse (*b*) is erected upon a rock of that name ten miles from shore, off Plymouth, England. A lighthouse was built on the spot, 1696 – 99, by Winstanley, who perished with it in a storm, November 27, 1703. Rebuilt of wood in a

Fig. 2947.



Lighthouses

a, the Egyptian *Phah*. *c*, the Bell Rock Lighthouse.
b, the Eddystone Lighthouse. *d*, the Skerryvore Lighthouse.

different form by Rudyard, 1706, and burnt 1755. Rebuilt by Smeaton of dovetailed and metal-bound granite blocks, 1757.

The surface of the rock was irregular and inclined. It was cut into steps, the risers of which were notched so as to form dovetailed mortises for the similarly shaped blocks of the stones in the course which interlocked with it. Each block had a level bearing, and the outside pieces were guarded by a border of rock which rose around them. The stones in a course were dovetailed together and additionally secured by cramps. The respective courses were secured to those above and below by dowel-pins consisting of tree-nails.

Six courses (8 ft. 4 in.) brought the structure to a level surface, eight other courses are solid, and from this point the structure is made hollow. The hight of the tower and lantern is 85 feet 7 inches. It was built in 421 working-days, being finished October 16, 1757.

The light was originally a chandelier with twenty-four candles. It is now a catoptric light, — an Argand lamp and parabolic reflectors. The change was made in 1807.

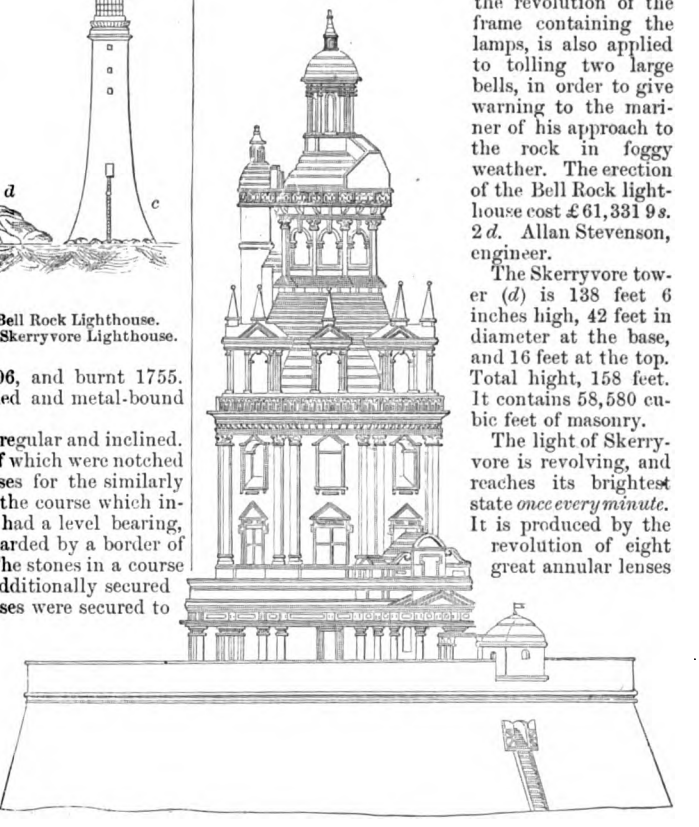
The Bell Rock lighthouse (*c*), on the rock once called the Inch-Cape and celebrated in a ditty by Southey, was erected 1807 – 10. The rock is off the Frith of Forth, and is 230 × 427 feet, eleven miles from land. The surface is bare at low water. The lighthouse is built in the manner of the Eddystone, the stones being joggled together, and the layers doweled together by tree-nails. Holes were bored in a circle of 36 feet diameter, and pieces of timber 50 feet in length inserted to support a temporary shelter for 30 workmen during the summer months. The structure is 42 feet diameter at the base, 13 feet at the top. The lower solid portion is 30 feet; total hight, 115. The door is 30 feet from the base.

The lantern is 12 feet in diameter, 15 feet high, has a balcony around it, is framed of cast-iron, and has plate-glass sides, the panes being 27 × 30 inches.

The light is a catoptric, the parabolic reflectors being 24 inches across. It is visible 18 or 20 miles distant.

The light is a *revolving red and white light*, and is produced by the revolution of a frame containing sixteen Argand lamps placed in the foci of paraboloidal mirrors, arranged on a quadrangular frame, whose alternate faces have shades of red glass placed before the reflectors, so that a red and a white light are shown successively. The machinery, which causes the revolution of the frame containing the lamps, is also applied to tolling two large bells, in order to give warning to the mariner of his approach to the rock in foggy weather. The erection of the Bell Rock lighthouse cost £61,331 9*s.* 2*d.* Allan Stevenson, engineer.

Fig. 2948.



Tour de Corduan (*Elevation*).

The Skerryvore tower (*d*) is 138 feet 6 inches high, 42 feet in diameter at the base, and 16 feet at the top. Total hight, 158 feet. It contains 58,580 cubic feet of masonry.

The light of Skerryvore is revolving, and reaches its brightest state *once every minute*. It is produced by the revolution of eight great annular lenses around a central lamp with four wicks, and belongs to the first order of dioptric lights in the system of

Digitized by Google

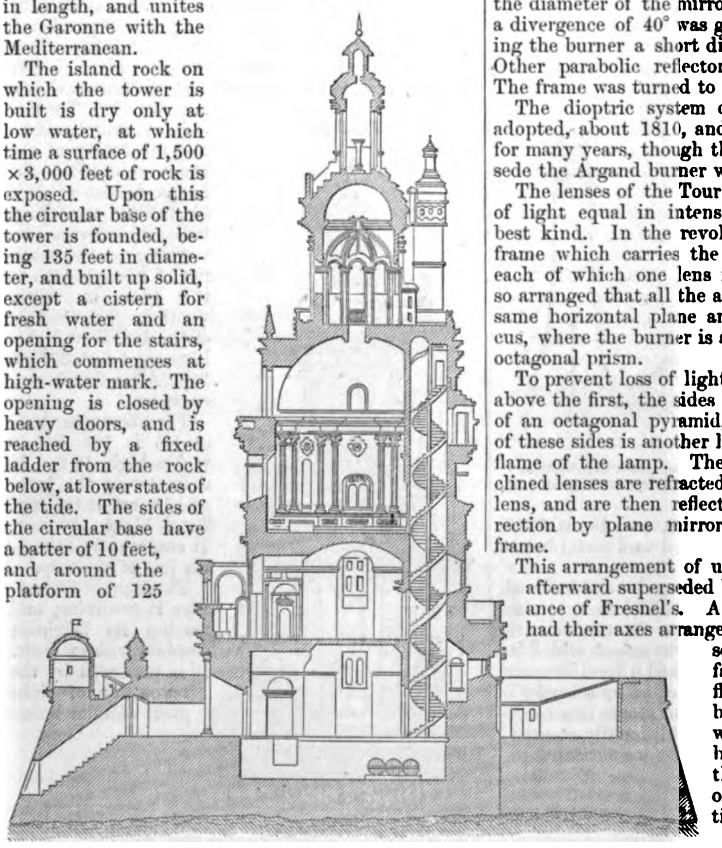
Fresnel. It may be seen from a vessel's deck at the distance of eighteen miles. The entire cost of the lighthouse, including the purchase of the steam-vessel, and the building of the harbor at Hynish for the reception of the small vessel which now attends the lighthouse, was £86,977 17*s.* 7*d.*

The Tour de Corduan is the most magnificent lighthouse of modern times. It is situated on a rock at the mouth of the Gironde, one of the most important rivers of France. This tower is 182½ English feet in hight, and is built in the Ornante Renaissance style of the period. It was commenced under the reign of Henry II., in 1584, and finished in that of Henry IV., in 1610. The architect was Louis Le Foix.

The commercial city of Bordeaux is situated upon the river 70 miles from its mouth, and at the time the lighthouse was built it had another special value, as it was a part of the projected chain of water-courses connecting the Bay of Biscay with the Mediterranean. This was effected shortly afterward by the canal of Languedoc, which is 150 miles in length, and unites the Garonne with the Mediterranean.

The island rock on which the tower is built is dry only at low water, at which time a surface of 1,500 × 3,000 feet of rock is exposed. Upon this the circular base of the tower is founded, being 135 feet in diameter, and built up solid, except a cistern for fresh water and an opening for the stairs, which commences at high-water mark. The opening is closed by heavy doors, and is reached by a fixed ladder from the rock below, at lower states of the tide. The sides of the circular base have a batter of 10 feet, and around the platform of 125 feet diameter thus made, is a wall 12 feet thick at its base and 12 feet high.

Fig. 2949.



Tour de Corduan (Section).

On the central circular area of 100 feet diameter is erected the tower, which has 50 feet diameter at the base, and has several stories diminishing towards the summit. The lower story is Doric, the 2d and 3d Ionic, the 4th Corinthian, the 5th Composite. The interior was handsomely decorated and furnished; the apartments of the 1st and 2d stories being finished for domestic use, store-rooms, etc.: the 3d was a handsome circular chapel, 31 feet in diameter, and having a dome 40 feet high. Upon this was erected the Corinthian cupola 27 feet high, which was 21 feet in diameter, had a stone balustrade around it, and supported the lantern, which formed the summit and was 5 feet internal diameter, 9 feet externally, and 17 feet high.

When this tower was erected the light was made by blazing wood, which was burnt in the lantern in a cresset. Coal was afterwards substituted. The smoke rose through an opening 18 inches in diameter in the dome of the lantern, passed into a finial chamber above, and escaped by side openings.

In 1727, the lantern was destroyed, and an iron one substituted by M. Betri.

In 1780, the catoptric system of lighting was introduced by Borda, an Argand burner being placed in the focus of a parabolic mirror formed of copper plated with silver. The focal length was about 4 inches, the diameter of the outer edge 21 inches. The beam of projected light was a cylinder equal to the diameter of the mirror. This being too partial, a divergence of 40° was given to the rays by removing the burner a short distance from the true focus. Other parabolic reflectors were afterwards added. The frame was turned to make the light revolve.

The dioptric system of Fresnel was eventually adopted, about 1810, and is likely to remain intact for many years, though the electric light may supersede the Argand burner which he used.

The lenses of the Tour de Corduan project a cone of light equal in intensity to eight mirrors of the best kind. In the revolving dioptric system, the frame which carries the lenses has eight sides, to each of which one lens is attached. The whole is so arranged that all the axes of the lenses are in the same horizontal plane and meet in the common focus, where the burner is situated, forming one large octagonal prism.

To prevent loss of light, a second frame is placed above the first, the sides of which form the frustum of an octagonal pyramid, and incline 50°; on each of these sides is another lens, having its focus in the flame of the lamp. The rays which fall on the inclined lenses are refracted parallel to the axis of the lens, and are then reflected into the horizontal direction by plane mirrors placed above the upper frame.

This arrangement of upper lenses and mirror was afterward superseded by another elegant contrivance of Fresnel's. A series of triangular prisms had their axes arranged in horizontal planes, and so adjusted that the light falling on the face next the flame was thrown upon the back of the prism, where it was totally reflected; and by a second refraction at the third side of the prism, it obtained its horizontal direction.

For fixed dioptric lights, the lenses are combined into a cylinder which makes an equal dispersion at all points of the horizon. The refracting apparatus of numerous lenses arranged polygonally has given way to the cylindrical lens. See DIOPTRIC SYSTEM OF LIGHTING.

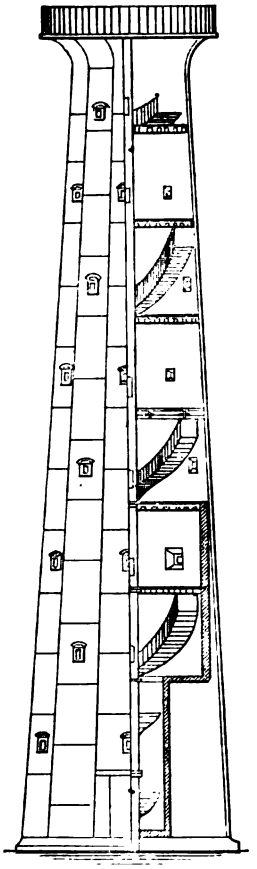
Fresnel's adaptation of the Argand lamp consists of four concentric burners protected from excessive heat by a superabundant supply of oil which is pumped into the wick-tubes, and constantly overflows.

Digitized by Google

The oil of colza (*Brassica campestris*) is used, and abundant ventilation is afforded by a lofty chimney.

The first screw-pile lighthouse actually erected prior to February, 1841, was at Port Fleetwood, near Lancaster, England. The screws which entered the bed of the river supported piles having screws at their upper ends, to which the timber columns supporting the frame of the superstructure were secured. These were united together by diagonal braces extending from the foot of one to the top of another. The first cast-iron lighthouse was put up at Point Morant, Jamaica, in 1842. The tower is formed of 9 tiers of plates, 10 feet high and $\frac{3}{4}$ inch thick, united to each other by bolts and flanges on the inside. The plates of each tier have a common radius. It was filled in with masonry and concrete to the hight of 27 feet, and rested on a granite foundation.

Fig. 2950



Iron Lighthouse, Bermuda.

Its total hight was 96 feet, the upper and lower diameters being respectively 18 feet 6 inches and 11 feet.

Fig. 2950 is a cast-iron lighthouse on a plan similar to the foregoing, subsequently erected at Bermuda. It is 105 feet 9 inches in hight, the lower diameter being 24 feet in addition to the flanges by which the plates of each tier are secured to each other, and those which united the successive tiers. They are strengthened by angular feathers $\frac{1}{2}$ inch thick.

Fig. 2951 represents one of two similar lighthouses erected by the United States government at Trinity Shoals and Timbalier, in the Gulf of Mexico. It is supported upon 9 screw-piles, — a central one surrounded by 8 others at distances of somewhat less than 15 feet 4 inches, — each being 20 feet distant from the central one, and secured together at the ground by adjustable wrought-iron links, and above by diagonal braces, and by radial struts to the central pile. The summit of each pile is encased in a cast-iron socket for receiving the column and the radial and diagonal braces. The jointed columns which support the lantern have a similar provision for their diagonal braces, the arrangement of which will be understood from the illustration. The different series of columns are joined together by sleeves. The first series above the foundation is 20 feet long, the second 15 feet, the next two 18 feet, the fourth, fifth, and sixth being respectively 15 feet 6 inches, 14 feet, and 12 feet 6 inches. The columns of the first series are of wrought-iron, forged tapering; those above are of hollow cast-iron, each series successively decreasing in diameter. The lantern is supported on a cylinder of boiler-iron resting on a platform at the top of the columns.

Light, November, 1866; Cape Grisnez, France, February, 1869; Souter Point, England, January, 1871; South Foreland, England, with two lights, January, 1872, in the first place in 1858–60 by Professor Holmes, and afterward England took the lead in this matter of the adaptation of electric illumination to lighthouse purposes. The Bishop rock light, Scilly Islands, the old Cassiterides of Herodotus, 145 feet high, cost £36,559. In the British Isles there are 357 shore lights and 47 floating lights. The French have 224 shore lights. The average annual expense in England of a shore light is £500; of a floating light, £1,200.

The lighthouses of the world are estimated at 2,814.

* For a geographical or nautical mile, the curvature equals 7.962 inches.

Light'ing. (*Metallurgy.*) Heating metal and allowing it to cool gradually. *Annealing.* The term is especially applied to the heating after hammering or rolling, to restore ductility.

Light'ing-de-vi'ces. 1. Two pieces of wood may be rubbed together so as to char the frictional surfaces and eventually produce flame. This may be assisted by tinder, punk, etc., which readily take fire.

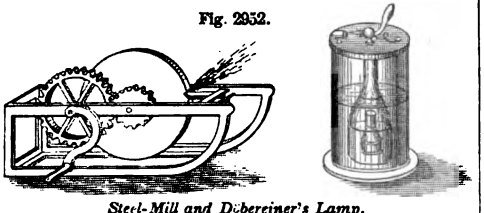
2. Iron may be hammered till it acquires a red heat, and is capable of firing combustible matters.

3. Steel struck by a flint yields sparks, which, falling upon charred linen, cause it to burn sufficiently to inflame sulphur.

This device amplified gave rise to the *miner's steel mill.*

4. The *miner's steel mill*, as it is called, has a steel wheel rapidly revolved by gearing and hand-

Fig. 2952.



Steel-Mill and Döbereiner's Lamp.

crank, its periphery being in contact with a flint fixed to a holder on the frame. It was operated by a child, who waited upon the miner and lighted him at his work.

It was superseded by the safety-lamp of Sir Humphry Davy. See SAFETY-LAMP.

5. Alum, sugar, and flour, when mixed and calcined, have a tendency to take fire when exposed to the atmosphere. Hence *Homberg's pyrophorus.* See PYROPHORUS.

6. Chlorate of potash mixed with sugar kindles into flame on the contact of sulphuric acid. The matches were dipped successively in melted sulphur and then in chlorate of potash, and were ignited by pressing the prepared ends upon a sponge of asbestus saturated with sulphuric acid and placed in a bottle. This was the *Promethean.*

7. Phosphorus, placed between the folds of a piece of paper and rubbed to and fro, will heat sufficiently to kindle a sulphur match. Hence the *phosphorus light* in use in 1675.

8. The *phosphoric tapers* were of wax, having wicks coated with phosphorus. They were inclosed in glass tubes hermetically sealed. They were ignited by cutting off the end of the tube with a file, when the phosphorus became ignited by the action of the air.

9. The *phosphorus bottle* was a small vial, into which a piece of phosphorus was placed and stirred around with a hot wire. The phosphorus being partially burnt emitted fumes which coated the inside of the vial with oxide of phosphorus. The vial was then tightly corked. In use, a match dipped in sulphur was dipped into the phosphorus, and flame resulted from the energetic action of the two.

To expedite the flame, the match, after dipping, was rubbed on the cork or a piece of wood.

10. When chromic acid is brought in contact with alcohol it parts with its oxygen so rapidly as to cause ignition. Mix gently in a mortar a small portion of chromic acid and one fourth the quantity of powdered camphor; a few drops of alcohol dropped upon it from considerable hight will cause ignition and deflagration.

11. Phosphorus and chlorate of potash rubbed together in a mortar will explode.

12. Potassium has such energetic affinity for oxygen as to decompose water when brought into contact therewith; the oxygen combines with the metal to form potash, and the hydrogen is ignited. A parallel effect takes place in regard to sodium when the water is previously heated.

13. Ammonia added to a solution of chloride of gold produces a yellowish-brown precipitate (*aurate of ammonia*), fulminate of gold. This explodes by friction. See FULMINATE.

14. Volta's *inflammable air-lamp* was a glass reservoir charged with hydrogen gas, which could be expelled in a jet as required. Upon the pedestal was an *electrophorus*, by which a spark could be emitted in the path of the jet which was lighted thereby. This was the precursor of the *hydrogen-lamp* and of a whole train of ingenious devices, the culmination of which is found in apparatus for lighting gas by electricity, erected on a large scale in the Capitol of the United States. See LIGHTING GAS BY ELECTRICITY.

15. Döbereiner's inflammable lamp (Fig. 2952) has a flask attached to a plate and stop-cock, and suspended in a receiver containing sulphuric acid and water. A piece of zinc is suspended in the inner vessel in contact with the acid, and the evolution of gas in the upper part of the flask forces the dilute acid out at bottom into the surrounding receiver, and stops the evolution of gas. When the stop-cock is turned, a jet of gas issues and impinges upon a piece of spongy platinum, which becomes red-hot and ignites the jet. The escape of gas allows the acid to rise in the flask, and the evolution of gas is resumed.

Digitized by Google

16. In the line of the voltaic phenomena must next be cited the heating of a platinum wire by an electric current derived from a pair of voltaic plates in an acid bath. Touchwood, a match, or a jet of gas in contact with the incandescent wire become inflamed. This device and the electric spark produced at the interval of a broken circuit are the means for lighting gas by electricity.

17. Air compressed to a sufficient extent in a tube in which is a piece of German tinder becomes heated so as to kindle the tinder, which will then ignite a brimstone match. This was called the *pneumatic tinder-box* or *light-syringe*.

18. The *oxymuriate matches* were founded upon the action of a compound of chlorate of potash and sugar when exposed to sulphuric acid.

These substances made into a paste with gum and colored by vermilion were used to tip splints. These were dipped in sulphuric acid to inflame them. To these succeeded the *lucifer-match*.

19. The *lucifer-matches* were originally tipped with a paste of chlorate of potash, sulphuret of antimony, and starch, and were drawn between two sand-paper surfaces. This was the inauguration of the friction-match, and the ignition produced a detonation.

20. The *Congreve match* substituted phosphorus for sulphide of antimony, and the match ignited on any rough surface. The substitution of saltpeter for chlorate of potash produced quiet ignition. Introduced in 1834.

Then followed the substitution of saltpeter for chlorate of potash, so that both the original articles were superseded, greater safety and comfort being attained.

The chemical reactions are as follows: —

The phosphorus is ignited by frictional compression.

The heat evolved decomposes the saltpeter.

The evolution of oxygen supports the flame and enables the ignition of the sulphur.

The burning sulphur ignites the wood.

Stearine was then substituted for the sulphur, into which the match was dipped before tipping with the more inflammable compound.

Light'ing Gas by E-lec-tric'i-ty. A means of lighting gas by developing a spark or producing a red heat in a platinum coil at the jet of issuing gas.

It is used in situations difficult of access, such as the rotunda, dome, and tholus of the Capitol at Washington, and the Senate and House of Representatives, whose gas-burners are above the glass ceilings in a chamber below the roof. Gardiner's apparatus, used in the dome and tholus, was the subject of a report by a commission consisting of Messrs. Shaffner, Pike, and Knight.

From the report the following is extracted: —

"The gas-pipe connections consist of circles of burners at 45, 80, and 165 feet from the floor of the rotunda, and are furnished with 300, 325, and 425 burners respectively. In addition to these, a cluster of 90 burners is placed in the tholus at a hight of 264 feet from the floor, and, being 60 feet above the crown of the dome, is, of course, invisible from the interior, but is a beautiful object viewed from the Capitol grounds, and visible at a distance of many miles.

"The flow of gas at each tier, and in the tholus, is equalized by a regulator, and governed by a stop-cock, the latter being opened and closed by electro-magnetic engines in their immediate vicinity, worked from the battery, the central brain of the apparatus from which ramifies the nervous fluid which vitalizes the motive agents and the illuminating coil of each of the 1,130 burners.

"The battery occupies an elliptical room 45 by 36 feet, and consists of 200 glass jars of a depth and diameter of about 13 inches, containing two zinc plates 9 by 10 inches, weighing 6 pounds each, and an interposed carbon plate, all supported by suitable insulators in the acid bath. It is disposed on benches in concentric series in the room, and arranged in sections of 20 jars each, to be brought into service as required.

"The connections consist of five miles of No. 10 copper wire, doubly wrapped with linen yarn, and, when necessary, incased in india-rubber tubing: this is securely laid in protecting pipes or through passages drilled through the walls, the return circuit from the engines and the burners being made through the gas-pipes.

"The burners used have an indestructible lava tip, which acts as an insulator, and each is provided with an insulated coil of platinum wire, placed on one side of the orifice, so as not to interfere with the free exit of the gas, which is lighted by exposure to the red-hot metal when the electric connection is made.

"The tiers of burners are divided into sections of from 30 to 50 burners, each section having independent connection with the instrument, so that a tier being divided into ten sections, it is lighted by a corresponding number of pulsations following the flow of the gas, which is turned on by the electro-magnetic engine belonging to and in the vicinity of the tier. The manipulation which, by successive pulsations, operates the engines, makes the series of illuminating connections, and registers the work, is performed in a passageway leading north from the floor of the rotunda, and perhaps 50 feet from the battery.

"The electro-magnetic engines consist of a double helix, with a sliding armature, on which is a latch which operates a ratchet-wheel on the axis of the stop-cock. The operator, by a succession of electric connections, works the armature piston, and turns the plug of the stop-cock such a fraction of a revolution as is represented by a number of teeth on the ratchet-wheel.

"The dial-plate has eleven keys, with a corresponding number of verniers.

"The primary electric connection with the battery is made by a stud in the central key, which, by rotation, is made to bring such a portion of the battery into play as may be required, a vernier indicating the extent of battery connection which takes place in successive sections of 20 jars.

"The surrounding keys, ten in number, are equally divided between the duties of turning on the gas and lighting the same at the five levels for which the dial-plate and keys are adapted. But four of these are yet arranged, consisting of the tiers at the elevation of 45, 80, and 165 feet, respectively, and the tholus at 264 feet.

"The fifth may be used for a tier at the spring of the dome, or a circle to illuminate the pictures.

"Each gas-key has a dark and a light segment on its disk, which are exhibited at an opening in the dial-plate, in correspondence with the closed and open position of the stop-cock, which governs the flow of gas at the tier represented by the said key.

"Each lighting key has a pointer, which indicates on its vernier the extent to which the electric connection has been made in the sections of the tier to which it belongs."

Another form of apparatus consists of a galvanic battery, Ruhmkorff's induction coil, and conducting wires, which are broken near the gas-jets so that an electric spark is produced by a charge of electricity leaping to the "tips" of the burners, each

Digitized by Google

burner being insulated, and forming a part of the circuit. The ends of the wires from which the spark proceeds are covered with platinum to prevent their corrosion.

One or the other plan is adopted in many public buildings, theaters, halls, and large stores, and it is proposed to light the street-lamps of cities by this means. A large circuit of lamps, embracing the streets of a ward or district, are connected by insulated wires proceeding from a conveniently situated battery, either magno-electric or voltaic. See also ELECTROPHORUS.

Light'ning-ar-rest'er. A device used in telegraphy for guarding against passage of atmospheric electricity through the instruments.

The line wires are attached to a plate of brass, usually serrated on the under side. This plate rests upon another plate connected with the ground, the two plates being separated by a thin layer of insulating material.

As lightning possesses enormous tension, preferring a short route even through a poor conductor to a longer one through a good conductor, it forces its passage through the layer of insulating material and thence to the ground, or *vice versa*. See LIGHTNING-DISCHARGER.

The Stoics distinguished two things in thunder, the lightning and the noise. They looked upon the first as the effect of the latter, which was properly what they termed thunder; for, according to them, thunder was occasioned by the shock of clouds, and lightning was the combustion of the volatile parts of the cloud, set on fire by the shock. Chrysippus taught that "these effects were coincident, and that our perception of the lightning before the thunder-clap is owing to our sight being quicker than our hearing."

Light'ning-con-duct'or. A metallic conductor intended to establish a definite line of least resistance between two bodies in opposite electrical states. The resistance of the line should be so small that no destructive effect shall arise from any discharge along it. Lightning-rods are included under this general definition.

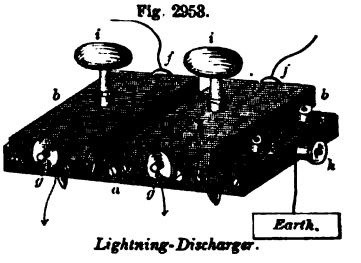
"The most important ancient notice of the relations between lightning and conducting metals appears to be that of Ctesias. He had possessed two iron swords, presents from the King Artaxerxes Mnemon and from his mother Parysatis, which, when planted in the earth, averted clouds, hail, and strokes of lightning. He had himself seen the operation, for the king had twice tried the experiment before his eyes. The exact attention paid by the Etruscans to the meteorological processes of the atmosphere in all that deviated from the ordinary course of phenomena makes it certainly to be lamented that nothing has come down to us from their Fulgural books. The epochs of the appearance of great comets, of the fall of meteoric stones, and of showers of falling stars, would no doubt have been found recorded in them, as in the more ancient Chinese annals, of which Edouard Biot has made use. Creuser has attempted to show that the natural features of Etruria may have influenced the peculiar turn of mind of its inhabitants. A 'calling forth' of the lightning, which is ascribed to Prometheus, reminds us of the pretended 'drawing down' of lightning by the Fulguratores. This operation consisted in a mere conjuration, and may have been of no more efficacy than the skinned ass's head, which, in the Etruscan rites, was considered a preservative from danger in thunder-storms.

"In the very complicated Etruscan augural theory, a distinction was made between the 'soft reminding lightnings sent by Jupiter from his own perfect power, and the violent electrical explosions or chastening thunderbolts which he might only send constitutionally after consultation with the other twelve gods.'" — HUMBOLDT.

Light'ning-dis-charg'er. (*Telegraphy.*) A device to protect telegraphic apparatus from the effects of atmospheric electricity passing over the wires.

In Fig. 2953, *a* is an iron plate called the earth-plate, over, but not in immediate contact with which are two smaller plates *b b* called conductors; each plate has two screws for attaching wires. To the screws *f f* are attached the up and down wires respectively; to the screws *g g*, the wires leading to the apparatus; and to the screw *h*, the earth-wire. The upper plates *b b* are kept in place by small knobs *i i*, attached to them and by buttons *k k* on the earth-plate. In order to prevent metallic contact, these, as well as the sides of the earth-plate, are covered with vulcanite. The atmospheric electricity, on reaching the conductors, springs over to the earth-plate, and is thus diverted from the apparatus. See also PARAGRELE.

Fig. 2953.



Lightning-Discharger.

Light'ning-rod. A form of lightning conductor, attached to a structure for the purpose of protecting it from lightning.

It is preferably made of copper, that metal having a greater conducting power than any other, but iron is the material usually employed.

The alleged improvements since its invention by Dr. Franklin are innumerable; most of these are, however, worthless, or of a trifling and unimportant character.

The first lightning-rod erected with a definite purpose of protection was put up by Benjamin Franklin soon after 1752, when he brought down electricity from a thunder-cloud. The first in England was set up at Payne's Hill, by Dr. Watson. In 1766 one was placed on the tower of St. Mark at Venice; it has since escaped injury, though previously it had been frequently struck by lightning.

Great opposition was at first raised against the invention, and the charges of impiety were revived; but the centuries were exploding these notions, and Franklin held his ground. After the theory was admitted, a curious war arose. *Knobs* against *points*. Benjamin Franklin said *points;* but as he was a rebel, King George III. and his admirers of course declared for *knobs*. Franklin, who could handle a pen like a cimeter, wrote: "I enter into no controversy. I leave my philosophical opinions to take their chance in the world. If they are right, truth and experience will support them; if wrong, they ought to be refuted and rejected. Disputes are apt to sour one's temper and disturb one's quiet. I have no private interest in the reception of my inventions by the world, having never made, nor proposed to make, the least profit by any of them. The king's changing his pointed conductors for blunt ones is, therefore, a matter of small importance to me. If I had a wish about it, it is that he had rejected them altogether as ineffectual. For it is only since he thought himself and family safe from the thunder of heaven that he dared to use his own thunder in destroying his innocent subjects."

Digitized by Google

The king requested the president of the Royal Society to resign, because he could not see with royal eyes. The knob theory has long since been entirely exploded.

Sir W. Snow Harris's lightning-rod for land use consists of wide bands of copper or of copper tubing, the metal of either being $\frac{1}{4}$ inch thick. The metal is prepared in lengths of 10 feet. The sections of tubing are united by intermediate screw sections. The strip conductor is nailed to the wall; the tube is secured by coupling-pieces. The upper extremity has a bayonet-point 18 inches long, $\frac{3}{4}$ inch in diameter at the point of connection to the solid plug with which the tube terminates. The ground connection consists of a descending rod and a cross rod, giving 3 divergent branches.

Harris's lightning-conductor for vessels converts the masts into lightning-conductors by the insertion in grooves of a double set of copper plates, connecting by bands of copper leading through the side under the deck-beams, and with the large bolts leading through the keel and keelson. The system is designed to include all large metallic masses in the hull.

These plates are from 1 to 4 inches wide, curved so as to correspond to the round of the mast, into which they are inlaid longitudinally. They are from $\frac{1}{16}$ to $\frac{1}{4}$ inch thick, 4 feet in length, and are secured by copper nails at intervals of 6 inches.

According to the opinion of Sir W. Snow Harris and other eminent electricians, the insulation of a metallic conductor by inclosing it in a glass tube or by glass supports is unnecessary if the continuity of a sufficient conductor be preserved. Harris states that the electrical discharge does not quit an easy line of transit such as is furnished by a copper rod of sufficient size, to pass to other bodies out of the line. He considers it unlikely that the lightning would leave such a rod even to reach metallic clamps, but it would be unwise to put such temptation in its way, unless the clamps were so connected with the ground as to make them a part of a continuous line of descent.

It is very important to make ground connections for extensive areas of iron surfaces such as are found in the rods, iron beams and joists, copings, lintels, thresholds, stairs, chimney, window, and door caps, window-casings, pillars, etc. This matter is not much attended to, however, but iron is inserted wherever convenience dictates, regardless of all electric considerations.

The conductors should be prolonged until reaching moist soil, or if this be impracticable should be carried, at a depth of two feet or more, to a distance of some 30 feet from the building, or connected with old chain conveyed to a similar distance; the trench in which it is laid being partially filled with carbonaceous matter.

In regard to the area protected by a rod, a difference of opinion exists, and the matter cannot be considered as determined. The opinion of Leroy, 1788, was that it protected a space around equal to three times the hight of the rod. The Academy of Sciences of Paris, 1823, opined that it protected a circular space whose radius is equal to the hight of the rod. This is the general opinion, but has no sufficient data for its foundation. It is, however, the basis of the American practice in putting up lightning-rods.

Professor Henry, a high authority on the subject, recommends a rod of round iron about 1 inch in diameter, terminating in a single platinum point, and secured to the building by iron eyes. Glass insulators he considers, as do other eminent electricians, of little importance. It should preferably be placed on the west side of the building in this latitude, and especially on that chimney from which a current of air ascends during the summer season, and should be connected where practicable with the water or gas pipes of the street. Where this is impracticable, connection should be made with a well always containing water, or with an iron plate buried in the ground. This rod may be put up by an ordinary blacksmith.

The lightning-rod invented by Moses G. Farmer of Boston is formed of a core of steel, which is first carefully tinned and then covered with copper, after which the compound wire is tinned, to prevent rusting.

Lightning-rods for powder-magazines were formerly erected on a mast at a short distance from the building. It is now thought advisable to attach them directly to the building in the following manner: A strip of copper is secured to the ridge of the building, at each end of which is a lightning-rod, of $\frac{1}{4}$ inch copper, projecting about 5 feet above the highest part of the building. Copper strips pass down the hips and are secured to the eave-trough, the water-pipes being connected with the underground conductor, which is divided into two branches at about 4 feet from the building. These are about $2\frac{1}{2}$ feet below the surface, and are covered with coal-ashes and earth.

It is estimated that at least 50 persons are killed annually by lightning in the United States, 69 in France, and 22 in England, but no conductor has been contrived to be carried on the person, though it has been often suggested. The risk is so small, numerically considered, that it is not probable any great proportion of the inhabitants of any country will make special provision for avoiding the danger.

Professor Arago classed several well-known sites according to the frequency of their storms, from the best information he could obtain. His list begins as follows: —

	Days of Thunder per Year.
1. Calcutta averages	60
2. Patna (India) supposed to average	53
3. Rio Janeiro averages	50.6
4. Maryland (U. S.) supposed to average	41
5. Martinique averages	39
6. Abyssinia supposed to average	38
7. Guadaloupe averages	37
8. Viviers (France) averages	24.7
9. Quebec averages	23.3
10. Buenos Ayres averages	22.5
11. Denainvilliers (France) averages	20.6

The lowest average he gives is that of Cairo in Egypt, three days of thunder per annum. That of Paris and most of the European cities is about fifteen days. He estimates the days of thunder at New York to be about the same.

Fig. 2954 exhibits some of the numerous variety of rods for which patents have been secured in the United States.

a has a series of points formed of spiral coils combined with a tubular portion, forming the tip. The conductor is a flat strip.

b, a jointed tubular conductor for vessels. It is divided at the head of the lower mast, a branch leading down the shrouds on either side to the water.

c, an iron rod tipped with copper, the point of which is gilded.

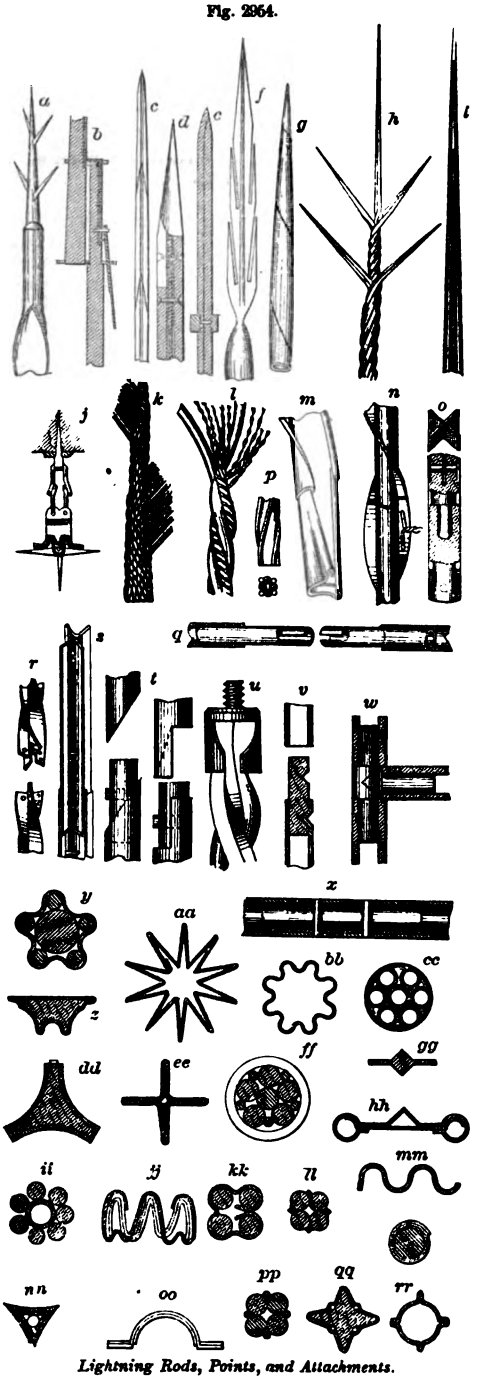
d has a central copper slip inclosed between iron side-pieces; the points of connection have interposed zinc plates.

Digitized by Google

e. The iron rod is grooved to receive a copper slip. The joints are secured by screw-threaded washers.

f. The point is formed with two opposite wings.

Fig. 2964.



Lightning Rods, Points, and Attachments.

g. The rod is composed of a single strip of copper wound spirally so as to form a tube.

h is composed of several strands of wire laid together so as to form a rope, and having several tips.

i. The point is formed of three or more metals inclosed one within the other, the most fusible outside.

j is an insulating attachment with additional conductor points at the coupling of rod-sections.

k. A copper cable, composed of a central wire rope and two exterior strands laid up in opposite directions.

l comprises two or more copper-wire ropes intertwined with an equal number of iron rods.

m. A series of metallic strips, forming a tube, are joined together.

n. A metallic strip is doubled up or corrugated, so as to form a tube with spiral flanges.

o. The joints of the rod are coupled by pieces cross-shaped in section and secured by rivets or bolts.

p has four twisted rods with wire worming.

q. The tubular sections are united by short pieces inside slotted, so as to form a species of bayonet-joint, and held by pins.

r is composed of two strips of sheet-metal, riveted together at their angles and twisted spirally.

s. The strips constituting the rod have slots through which staples are inserted to fasten them together.

t. The sections are connected by interior short pieces fastened to each by pins.

u. The exterior cable is stiffened by a spirally flanged core. The tip is fastened by a dovetailed coupling-screw.

v. The sections of the square tubular rod are secured to each other by square plugs fastened by indenting the tubes into suitable depressions formed in them, or by rivets.

w. The sections are coupled by an interior cylinder and a tapering plug projecting from each of its ends.

x. An interior tube with pins holds the ends of the tubular sections together.

y to *r r* inclusive represent sections of various kinds of patented rods.

Light-port. (*Shipbuilding.*) An opening in a ship's side provided with a glazed lid or cover. Sometimes called a *scuttle.*

Light-room. (*Nautical.*) A small chamber next to, but isolated from, the magazine. The latter receives its light through a glass partition between the two chambers.

Lights. (*Pyrotechnics.*) Pieces formed by pressing an inflammable composition, which burns with a white or colored light, into cases of large diameter or shallow vessels; such are Bengal-lights, blue-lights, etc.

Light-ship. A vessel moored in the vicinity of a dangerous shoal or headland, and carrying aloft a warning light. The first light-vessel moored on the coast of Great Britain was that at the Nore in 1734. There were, in 1850, 26 floating lights on the coast of England.

Stevenson states that the annual expense of maintaining a floating light, including the wages and victualing of the crew, who are eleven in number, is, on an average, £1,000; and the first cost of such a vessel, fitted complete with lantern and lighting apparatus, anchors, cables, etc., is nearly £5,000. The lanterns are octagonal in form, 5 feet 6 inches in diameter; and, where fixed lights are exhibited, they are fitted with eight Argand lamps, each in the focus of a parabolic reflector of twelve inches diameter; but, in the revolving lights, four lamps and reflectors only are fitted. The greatest depth of water in which any light-vessel belonging to the Corporation of Trinity House at present rides is at the

Digitized by Google

station of the *Seven Stones* between the Scilly Islands and the coast of Cornwall, and is about 40 fathoms.

Light-vessels are moored with chain-cables of 1½ inch diameter, and a single mushroom anchor of 32 cwt.; the chain-cables are 200 fathoms in length. Some of the vessels are moored to *span-ground* moorings, consisting of 100 fathoms of chain to each arm, and a mushroom anchor of similar weight at the end of each; a riding-cable of 150 fathoms is in such cases attached to the center ring of the ground-chain.

Lig'num-vi'tæ. The wood of a tree of the genus *Guiacum*, a native of the warm latitudes of America. It is hard and heavy, and is used for sheaves of ship's blocks, and for ninepin balls.

Limb. 1. The graduated arc or sector of a measuring or optical instrument.

2. (*Locksmithing.*) One of the pieces which compose a lock.

Limb, Ar-ti-fi'cial. See ARM, FOOT, HAND, LEG, ARTIFICIAL.

Lim'ber. 1. (*Gun-carriage.*) The detachable part mounted on the two fore-wheels, and to which the horses are attached. The gun is *limbered up* when the trail of the gun-carriage proper is lifted up and looped over the pintle-hook of the limber, in order for marching. See GUN-CARRIAGE.

The term *limber* is also applied to the fore-carriage of the ammunition-wagon to which the caisson or tumbril is connected.

Limbers differ in construction with the purpose and positions of the guns; as, —

The *casemate*-limber; the *field-gun* limber, with an ammunition-box; the *garrison-gun* limber; the limber with shafts; the *pole*-limber; the *siege-carriage* limber; the *battery-wagon* limber.

The parts of a limber are usually —

The axle, pole, futchels, pintle, pintle-bolster, bolster yoke-hook, bolster-plate, upper and lower pintle-plates, limber-wheel, ammunition-box, trail-ring, limber-hook, limber-chain, etc.

2. (*Shipwrighting.*) A passage on each side of the keelson for bilge-water. It is covered in by a movable board called a *limber-board*, whose edges rest respectively upon the *keelson* and *limber-strake*.

3. A shaft or thill of a vehicle.

Lim'ber-board. (*Shipbuilding.*) A plank reaching from the keelson to the limber-strake, and merely butting against the bulkheads, so as to be easily taken up to expose the *limbers*.

Lim'ber-chain. 1. (*Nautical.*) A chain passing through the *limber-holes* of a vessel by which they may be cleared of dirt that chokes them.

2. (*Artillery.*) A keep-chain which goes round the pintle and confines the trail to the limber, preventing its flying off the limber-hook.

Lim'ber-chest. The ammunition or tool chest belonging to the limber of an artillery-carriage of any description. Those of the gun-carriage and caisson are fitted up as ammunition-chests, while those of the forge and battery wagon contain respectively tools and stores for blacksmiths', and for carriage-makers' and saddlers' use.

Lim'ber-holes. (*Shipwrighting.*) Holes through the floor-timbers on each side of the keelson, to allow the passage of bilge-water. The row of holes constitutes the *limber-passage*.

Lim'ber-hook. (*Artillery.*) The hook on the limber to which the trail of the gun is attached.

Lim'ber-ing-up Hoop. (*Artillery.*) A stirrup-handle on the trail of a gun by which the piece is moved in limbering and unlimbering.

Lim'ber-strake. (*Shipbuilding.*) That strake of the inner skin which is nearest to the keelson. A space between it and the latter is called the *limber*, and forms a passage for bilge-water.

Lime. (*Sugar.*) Lime-water used in clarifying coarse sugar.

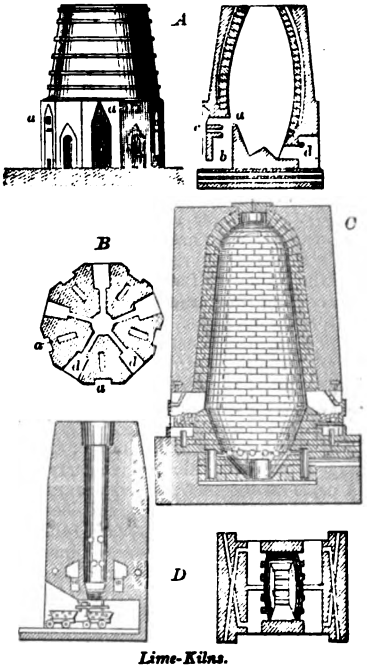
Lime-floor. A floor of lime-mortar, spread, beaten, and rubbed smooth.

Lime-kiln. Lime is derived from its carbonate, which exists in immense quantities in nature in the form of limestone, including marble. It is, where these are abundant, prepared from oyster-shells, which are also a carbonate of lime.

The process consists in calcining the carbonate in kilns, during which the carbonic acid is driven off, leaving oxide of calcium or quicklime.

The forms of kiln are various, probably the most primitive being made by excavating a hole in the earth in the shape of an inverted cone, in which alternate layers of limestone and fuel were placed, and

Fig. 2955.



Lime-Kilns.

the top covered with sods. Kilns having chambers in the form of an inverted cone are generally employed in places where materials are scarce and coal is the fuel used. The ovoidal form, truncated at its upper part, is, however, generally preferred, on account of its losing less heat by radiation, and allowing the upper portion of the lime to settle more gradually and evenly as the lower portion is withdrawn.

The kiln may be built of either stone or brick, either cylindrical or rectangular, and is usually erected against the side of a natural bank, or a mound is thrown up behind it.

A B represents a kiln used at Rudersdorf, Prussia, adapted to burn one part wood and four of turf. It has five fireplaces *a a*; *b* is an ash-pit; *c c* are openings for regulating the draft; *d*, openings for withdrawing the lime.

It is lined with a double thickness of fire-bricks, the space between which and the outer masonry is

Digitized by Google

filled in with well-rammed cinders to prevent loss of heat.

A continuous kiln, employed in Belgium, has eight openings for removing the lime, which is being continually withdrawn while fresh charges are added at the top. It is charged with alternate layers of coal and limestone, in the proportion of one coal to four limestone, and is allowed to cool but once a year, for inspection and repairs.

A kiln was invented by Count Rumford, having for its principal objects to consume the smoke, to bring a large surface of flame and hot vapor in contact with the limestone, to keep the latter separate from the fuel, and to allow the process to be continuous.

It consists of a truncated cone, some 15 feet high, 2 feet in diameter at base, and 9 inches at top. In order to retain the heat, the sides, which are of brick and very thin, are double and filled in with dry wood-ashes. The fuel is introduced through an opening above, which is covered by a hinged iron plate, raised and lowered by means of a chain, to regulate the draft. The opening for cleaning the fireplace is provided with a grate and ash-pit, and also, by causing a horizontal draft into the furnace, assists in consuming the smoke. The limestone is fed in at the top of the furnace. The products of combustion are directed downward before they are admitted into the body of the kiln, the unconsumed portion finally passing out at the top. The incandescent mass of lime below assists in heating the charge above. The lime is removed at an opening below, and fresh charges are added at the top as this is gradually withdrawn.

In the kiln *C*, blasts of air are forced through the burnt and cooling lime, and mingle with the caloric currents from the furnaces. The furnaces are placed around the kiln, and blasts of air forced through the fuel and through the top of the fire space.

The upper end of the kiln is arched over, and the feed-hole stopped with a removable cover having a perforation in its center.

In *D* the kiln has bottom discharge; the furnaces are arranged on each side and discharge into the kiln. A cross-arrangement of flues counteracts inequality of draft on the windward and leeward sides.

A kiln, invented by Mr. Booker of Dublin, having the form of two truncated cones joined at their bases, where the diameter is about 7 feet, tapering to 3 feet at top and bottom, and from 25 to 30 feet in hight, is said to have produced excellent results. A pivoted plate of iron is placed over the top for regulating the draft.

Artificial hydraulic lime is now manufactured on a large scale in England and France, and has been employed in a number of important works.

Two qualities are prepared by two different processes. The first, which produces the best lime but is most expensive, consists in mixing with rich slaked lime a certain proportion of clay, and calcining the mass.

In the second, some soft calcareous material is substituted for the lime, and the materials incorporated by grinding.

In an establishment at Meudon, near Paris, the materials made use of are the chalk of the vicinity and a clay from Vaugirard, in the proportion of four chalk to one clay. These, broken into lumps, are thrown into a circular basin, around which an upright millstone, having its axis attached to a vertical shaft, is caused to travel; this is provided with a follower, consisting of a wheel having attached toothed arrangements; by this the mixture is, with the addition of water, ground into a pulp, and is drawn off, descending successively into a series of chambers at different levels, until it attains the proper consistency for molding. The mass is then divided into regular and equal prisms by means of a mold, and these are placed on drying-shelves until sufficiently dry for burning.

Cato (150 B. C.) gave directions for forming a lime-kiln. He preferred a truncated cone, 10 feet in diameter at the bottom, 20 feet high, and 3 feet diameter at the top. The grate covered the whole bottom; there was a pit below for the ashes, and two furnace-doors, one for drawing out the burnt stone and the other for admitting air and fuel.

Lime-light. A light produced by projecting jets of ignited hydrogen and oxygen upon a ball of lime.

Invented by Lieutenant Drummond, who first applied it in the focus of a paraboloid for geodetic purposes. See DRUMMOND-LIGHT.

Lime-ma-chine'. (*Gas-making.*) A machine in which gas is purified by passing through lime. See GAS-PURIFIER.

Lime-paste. The cream of lime, produced by slaking with water.

Lime-pow'der. The decrepitated lime produced by air-slaking.

Lime-screen. A sifter for separating lime powdered by slaking from the lumps.

Lime-spread'er. A traveling box with perforated bottom, or other device, for distributing powdered lime over land as a manure.

Lime'stone. A rock composed of lime and carbonic acid.

The term in a geological sense includes *chalk* and *marble*, but technically these are distinct.

Limestones are often fossiliferous; in the metamorphic limestones, such as *statuary marble*, the traces of fossils are obliterated.

Siliceous limestones are mixtures of carbonate of lime and flint.

Magnesian limestone, *dolomite*, is a compound of carbonates of lime and magnesia.

Chalk is an aggregation of fossils, large and small. The latter are microscopic.

Oolite is composed of small, egg-like grains, each of which has a grain of sand as a nucleus, covered by concentric layers of carbonate of lime.

Pure carbonate of lime occurs in the form of calcareous spar, but is generally associated with other minerals. According to its combinations it is known as: —

Argillaceous.	Ferruginous.
Magnesian.	Bituminous.
Sandy.	Fetid, etc.

According to its texture it is known as: —

Lamellar.	Oolitic.
Saccharoid.	Chalky.
Granular.	Pulverulent.
Compact.	Concreted, etc.

Lime'stone-me'ter. An instrument invented by Dr. Ure for ascertaining the proportion of calcareous matters in soils. See Ure's Dictionary, II. pp. 689, 690 (Am. ed.).

Lime-wa'ter. A solution of lime prepared by mixing hydrate of lime with boiling distilled water.

Lim'ing. 1. (*Leather-manufacture.*) The operation of steeping hides in lime-water or milk of lime, to remove the hair. The action of the lime is to dissolve the hair sheath and form a soap with the fat of the hide. *Unhairing.*

2. Slaked lime thinned with water, used in bleaching.

Digitized by Google

Limp. The sheet-iron scraper wherewith the top layer of poor ore is removed from the sieve.

Linch-pin. (*Vehicle.*) A pin passing vertically through a mortise near the end of the *spindle* or *arm* of an *axle*, and serving to hold the wheel on the spindle. The ring on the end of the axle is the *linch-hoop*.

With *thimble-skein* wagons, a nut takes the place of the linch-pin. See AXLE.

The chariots of Egypt had two wheels, with 6 spokes each. Sometimes the wheels were fast to the axle like our railroad wheels; sometimes they ran upon the axles, like our carriages: in the latter case, they had bronze *linch-pins*, as shown at Aboosimbel and at Thebes. No screw in old Egypt.

Line. 1. (*Fiber.*) The finer and longer stapled flax separated from the shorter, *tow*, by means of the HACKLE (which see).

2. (*Printing.*) An arrangement of letters and words across a page or column.

3. The twelfth of an inch.

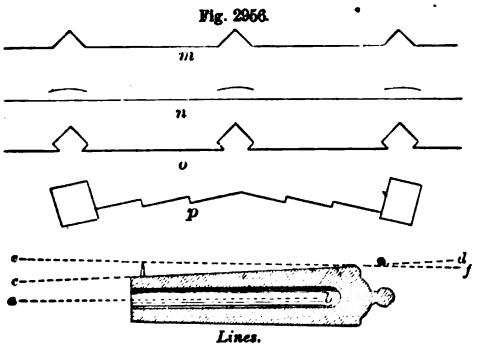
4. A measuring cord, or one for tying or suspending objects, as a *tape*-line, *clothes*-line, *chalk*-line, etc.

5. (*Machinery.*) *a.* The truth of position; as an engine *in line*, that is, the motions of the piston, pitman, and crank-wrist in the same plane, and at right angles to the axis of the fly-wheel.

b. The line of centers. The dead point of a crank, when the connecting-rod and crank are in a straight line.

6. (*Fortification.*) A rampart. Continued lines

Fig. 2956.



Lines.

are used to inclose a front or to connect principal works with one another by a continuous parapet.

Redans, *tenailles*, or *bastions* are placed at intervals, for flank defense, and give rise to the terms, —

Redan line (*m*).

Tenaille line (*n*).

Bastion line (*o*).

Indented lines (*p*) have a succession of *faces* and flanks at right angles. The *faces* are four times the length of the *flanks*; the latter have an enfilading fire on the *faces* of the parapet.

Names defining position and relation are: —

Line of defense: extending from the projecting angle of a work to the exterior extremities of the flanks which defend it.

Line of circumvallation: a belt of field-works two or three miles from the place invested, facing the country.

Line of contravallation: a belt of field-works facing the place attacked.

Line with intervals: one having detached works which command the intervening space and enable them to support each other.

7. (*Shipbuilding.*) A delineation of the form of a vessel, representing vertical and horizontal sections.

a. Beam-line. The line indicating the intersection of the top of the beams with the frames of the ship.

b. Bearding-line. The trace of the inner surface of the ship's skin upon the *keel*, *stem*, and *stern-post*.

c. Boundary-line. The trace of the outside surface of the skin, corresponding to the outside edge of the rabbet.

d. Bow and *buttock* lines are the boundaries of the vertical sections of the ship, in planes parallel to the vertical longitudinal section.

e. Center-line. The central, vertical, longitudinal section.

f. The *cutting-down* line is a curve on the sheer plan, corresponding to the upper surface of the throats of the floors amidships and to the under side of the keelson.

g. Diagonal lines show the boundaries of various sections formed by planes which are oblique to the vertical, longitudinal plane, and which intersect that plane in straight lines parallel to the keel.

h. Level lines are similar to the water lines, excepting that they are parallel to the keel instead of to the surface of the water, or the *line of flotation*.

i. The *main-breadth* line is the boundary of the widest part of the ship in each of the three plans, — the *shear-plan*, *half-breadth plan*, *body-plan*.

j. Ribband-line. An oblique longitudinal section. See *Diagonal* line.

k. Sheer-line. The line of the deck at the side of the ship. The upward curvature towards the ends is called the *sheer*, and the effect is to raise the vessel to a greater hight out of the water at the stem and stern, where her motion relatively to the water is greatest.

l. Stepping-line. The *bearding*-line at the points where it curves upward towards the ends of the vessel.

m. The *top-breadth* or *top-timber* line is a line drawn to the sheer of the ship, fore and aft, at the hight of the under side of the gunwale amidships.

n. The *top-side* line is a sheer-line drawn above the *top-timber* line at the upper side of the gunwale.

o. Water-lines are straight and horizontal in the *sheer-plan* and curved in the *half-breadth plan*. They show the form of the ship at successive depths, as would appear by so many horizontal sections.

8. (*Nautical.*) *a.* A running cord or rope; as, *bowline*, *bunt* line, *clew* line, *spilling* line, etc.

b. A cord for a specific purpose; as, a *hand*-line, a 20-fathom sounding-line having a lead of from 7 to 14 pounds (see HAND-LINE). A *deep-sea* line, one of say 200 fathoms, and having a lead of 28 pounds weight (see DEEP-SEA LINE). A *fishing*-line.

c. A grade of rope, such as *marline*, *white* line, *tarred* line, etc.

9. (*Mining.*) *a. Line of bearing.* The strike of a stratum, or its direction at right angles to the *dip*.

b. Synclinal line. The axis of the valley curvature of strata, opposed to *anticlinal*.

c. Anticlinal line. The axis of the ridge or saddle curvature of strata, opposed to *synclinal*.

d. Line of least resistance. The *line of mine* or *axis of explosion*. A line drawn from the focus of a mine to that point in the direction of which the charge meets with the least resistance.

10. (*Architecture.*) *Springing* line. The line from which an arch rises, and from which the versed sine is calculated.

11. (*Masonry.*) The bricklayer's cord, which is his guide for level and direction. It is stretched between *line-pins*.

12. (*Railway-engineering.*) A railway-track, as

Digitized by Google

the *main* line or trunk. A *loop*-line, a *connecting* line, a *crossing* line, a *side* line or switch.

13. (*Telegraphy.*) The wire connecting one station with another.

The part of an instrument to which the *line* is connected is known as its *terminal*.

The wires and instruments form the *circuit*. See CIRCUIT; WIRE.

14. (*Surveying.*) *a. Base-line.* A carefully measured line which extends between two stations and forms the basis of triangulation.

b. Line of direction. The *bearing.* The line laid down or protracted in a survey.

15. (*Drafting* and *Perspective.*) *a.* The *ground* line or *fundamental* line. The common section of the ground plane and the base of the picture. The *terrestrial* line.

b. The *horizontal* line. The common section of the horizontal and that of the draft of representation, passing through the principal points.

c. The *visual* line. The line conceived to proceed from the object to the eye.

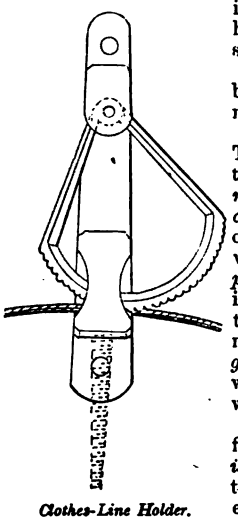
d. The *principal* line. A line drawn from the eye perpendicular to the picture. The *line of distance.*

16. (*Carpentry.*) To strike a straight line on timber or boards; usually a chalk line between points determined by measurement.

Lin'e-ar Mi-crom'e-ter. (*Optics.*) A graduated scale placed in the field of a telescope, and used to measure distances between objects.

Line-clamp. A device to hold a clothes or other line.

Fig 2937.



Clothes-Line Holder.

In the example, the line is clamped between the hook and the serrated swinging segment.

Lined-gold. Gold backed by a leaf of baser metal.

Line-en-grav'ing. This term is used to distinguish it from *aquatint, mezzotint,* and *stipple* or *chalk* engraving. It was originally entirely executed with the graver and *dry point.* The latter term is to distinguish it from the *etching point,* which makes a mark through a *ground* upon the plate, which is afterwards *bit in* with acid.

Latterly, the subject is first *etched* and then *finished* with the graver. Certain parts are left to be entirely executed by the graver and dry point, while other parts are deepened and made more effective by the application of the graver to the etched lines. Smooth portions are laid in by the *ruling-machine,* which has a *diamond-point* working through a ground upon the plate, and so arranged as to make a series of parallel marks at regulated distances. After *ruling,* the plate is *bit in* with acid, as described under ETCHING. (See RULING-MACHINE, ENGRAVER'S.) Line-engraving is generally admitted to be the highest style of the art.

Lin'en. (*Fabric.*) A cloth made of flax and having many grades of fineness, and several forms distinguished by their figures or surfaces; as *damask, diaper, cambric, huckaback,* etc.

The earliest notice of linen — cloth of flax — is in Egypt. In the time of Moses, the Pharaoh was arrayed in vestures of fine linen; and on the tomb of Beni Hassan are shown the pulling of the flax and the ridding of the seeds by means of the ripple. It was the only material allowed for the garments of the priests and the bandaging of the dead. The ceremonial law of the Hebrews also prescribes linen for the priests. Cotton was then unknown, except as a curiosity. Wool was regarded as foul. We read of the Egyptian linen in Genesis, Chronicles, Proverbs, and Ezekiel. Pharaoh arrayed Joseph in vestures of fine linen, 1716 B. C. The mixture of flax and wool in a fabric was forbidden (Lev. xix. 19). Solomon had linen yarn brought out of Egypt (1 Kings x. 28).

"He [Aaron] shall put on the holy linen coat, and he shall have the linen breeches upon his flesh, and shall be girded with a linen girdle, and with the linen miter shall he be attired; these are holy garments."

Wilkinson states that the ancient Egyptian linen is far superior to the finest modern in general quality and the evenness of the threads. One specimen has 540 threads or 270 double threads in the warp, and 110 in the woof.

In the linen corselet given by Amasis of Egypt to the Lacedemonians, each thread, though fine, was composed of 360 other threads, all distinct. It was handsomely embroidered. The tomb of Rameses III. at Thebes showed a similar corselet, worked with figures of animals. Pliny notices the corselet of Amasis, shown in the temple of Minerva at Rhodes. See FLAX.

It was first manufactured in England by Flemish weavers, under the protection of Henry III., 1253. Before this, woolen shirts were generally worn. A company of linen-weavers was established in London, 1368.

The Presbyterians, who left persecution in Scotland in the time of the Stuarts, planted the linen manufacture in the North of Ireland, and were encouraged by William III. and succeeding governments.

Lin'en Pa'per. As with paper of cotton, bamboo, morus bark, and silk, it appears that the first manufacture of linen paper was in China. The Egyptians excelled in fine linen in very early times. About 1500 B. C., the Israelites left Egypt with stores of linen; and five hundred years afterward, Solomon imported linen yarn from thence. Yet, with all this, it does not appear that the people of any country bordering on the Mediterranean had conceived the idea of tearing these rags to pieces, making them into pulp, and then into a sheet. See PAPER.

The use of papyrus itself, though it so much preceded any true paper, is by many persons supposed not to have antedated the expedition of Alexander. Without the papyrus, which so long gave the Egyptians precedence in the matter of written records, they must have been reduced to the same straits as their neighbors, and have written on waxed tablets, linen cloth, palm leaves, bark, etc. The use of parchment was not yet, if we may credit the assertion that it was invented by the king of Pergamus as a substitute for the papyrus, on which an embargo was laid by the reigning Ptolemy, whoever he was.

The use of linen paper in Europe appears to have originated in Germany, about the eleventh or twelfth century, the exact date being undeterminable. We read of a German paper-mill at Nuremberg in 1390, one in England in 1343, in France, 1314, Italy, 1367. Linen paper, however, is yet preserved, containing documents of much older date.

John Tate had a mill at Stevenage, England, in 1496, but the manufacture was much increased by

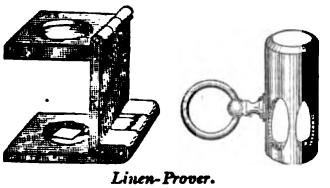
Digitized by Google

Spielman in 1588. This person was a German jeweler, and established a paper-mill at Deptford during the reign of Queen Elizabeth.

Whatman's mill was established at Maidstone in 1770. The name is yet a famous brand.

Lin'en-prov'er. A small microscope for counting the threads in linen fabrics. Its base has a square opening, which exposes a certain area of linen, and the glass above enables the number of threads to be counted.

Fig. 2958.



Linen-Prover.

Some linen-provers are provided with four perforations, which are respectively, —

$\frac{1}{4}$ of 1 inch. $\frac{1}{777}$ of 37 inches.
$\frac{1}{100}$ of 40 inches. $\frac{1}{100}$ of 34 inches.

See REED.

Line-of-bat'tle Ship. In England, a ship of not less than 64 guns.

Line of Cen'ters. (*Machinery.*) *a.* A straight line joining the centers of two wheels in gear.

b. The line when the crank and the connecting-rod are in a straight line. The *dead-point* of the crank.

Line of De-fense'. (*Fortification.*) A line joining a salient angle with the opposite flank. See LINE, 6.

Line of Fire. (*Ordnance.*) The line formed by the axis of the piece produced. When the gun is laid point-blank, the *line of fire* is parallel to the *line of sight*, and not otherwise. See Fig. 2956.

a b, line of fire.
c d, line of metal.
e f, line of sight (point-blank).

Line of Met'al. (*Ordnance.*) A line joining the notches on the breech and muzzle, and forming an angle with the axis of the bore, in consequence of the taper form of the piece. See Fig. 2956.

Line of Met'al-el-e-va'tion. (*Ordnance.*) The elevation due to the conical form of the gun when the line of metal is laid horizontal.

Line of Sight. (*Ordnance.*) The line passing through the breech and muzzle sights of a gun at any elevation and the object. See Fig. 2956.

Line-pin. (*Bricklaying.*) A pin used by bricklayers to hold the line by which the bricks are laid. Its pointed end is forced into a mortar-joint of the building.

Fig. 2959.

Line-Pins.

Lin'er. 1. (*Marble-working.*) A long slab of stone to which pieces of marble are secured in order to be ground or polished. The pieces of marble — for a tesselated pavement, for instance — are placed face downward on a flat stone; plaster of paris is poured on their upper surfaces, and the *liner* is laid upon them so as to be cemented to each, though they may vary in thickness. They are then ready for grinding by being drawn back and forth over a large slab of marble, sand and water being supplied between the surfaces, which act by mutual attrition.

2. (*Machinery.*) A thin piece placed between parts to adjust them. A *shim*.

3. (*Nautical.*) *a.* A line-of-battle ship. One large enough to occupy a position in the main line.

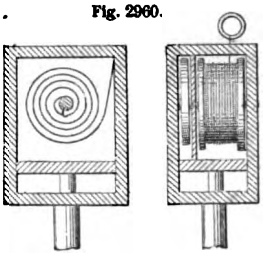
b. One of a regular line of vessels or packets sailing or steaming between ports.

Line-rock'et. (*Pyrotechnics.*) A small rocket made to run along an extended wire or line.

Lines. (*Saddlery.*) Another name for driving-reins.

Line-wind'er. A reel for a clothes-line, a fishing-line, a chalk-line, a log-line, etc. In the example, the line, after being withdrawn for use, is re-wound on the reel by a spring upon the reel-shaft.

Fig. 2960.



Chalk-Line Reel.

Line-wire. (*Telegraphy.*) The wire connecting stations. They are usually of iron, on account of its comparative cheapness, and its tenacity, which allows a long reach between posts. See INSULATOR; TELEGRAPH; and, for a specific index of related subjects, see ELECTRICAL APPARATUS AND APPLIANCES.

Lin'gel. A small thong of leather for sewing or lacing bands. *Lingle.*

Lin'got. An iron mold for casting metals.

Lin'guet. 1. A tongue; as in some organ-pipes. A *languet*.

2. The piece of a sword-hilt which turns down over the mouth-piece of a scabbard.

Lin'ing. 1. (*Joinery.*) Inside boarding; in contradistinction to outside *sheathing* or *boxing*, called *casing*. A covering of an interior surface, such as —

The *boxing* of window-shutters which form the backs of the recesses into which the shutters are folded.

The *facings* on each side of a doorway.

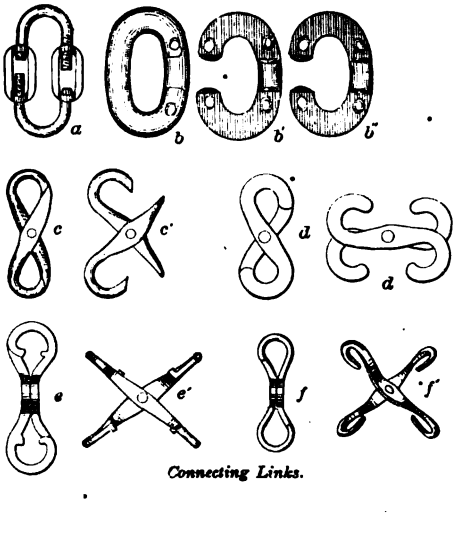
The vertical pieces of a window-way parallel with the surface of the wall.

2. (*Metallurgy.*) The *fixing* or protecting stuff on the boshes of a puddling-furnace. The inside surface material of a BLAST-FURNACE (which see).

3. (*Steam-engine.*) A non-radiating covering of felt, etc., for a steam-boiler. The term is hardly correct here, for the covering is exterior, and is properly known as *cleading*, *lagging*, or *jacket*.

4. (*Hydraulic Engineering.*) Puddle laid on the sides of a canal, to prevent the percolation of water.

Fig. 2961.



Connecting Links.

Digitized by Google

Link. 1. A short connecting piece of circular or other equivalent shape, as one of the oval rings or divisions of a chain.

The illustration shows several links capable of being taken apart, and thus becoming a means of uniting the broken ends of a chain. Each half of the link *a* has a swivel to which it is connected by a head, the swivel of each part forming a nut for the threaded leg of the other portion. The link *b* is made of two sections, *b' b''*, laid upon each other and riveted. The illustrations (*c c'*, *d d*, *e e'*, *f f'*) are forms of connecting link whose twin swiveling portions form a mousing for each other.

2. A short connecting bar with a bearing in each end, for transmitting motion from one rod or lever to another.

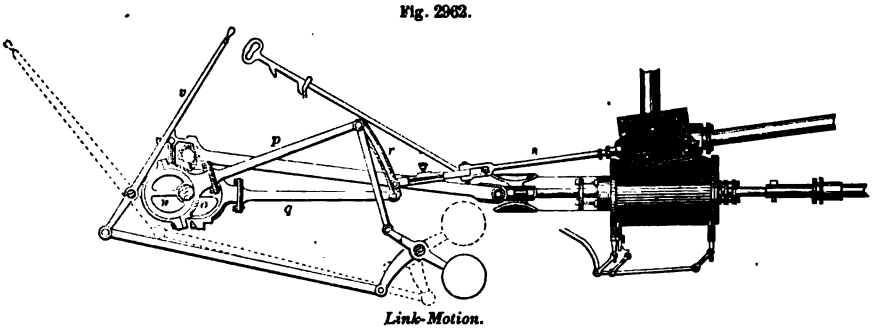
3. The length of one section of Gunter's chain, 7.92 inches, the 100th part of 66 feet.

4. A torch. It is made of tow and pitch, or of combustible splinters, such as of pitch-pine.

Link-motion. A gear by which the valve is operated in locomotives and similar engines. It acts as a variable cut-off, or reverses the steam, or renders the valve inactive, as may be required.

It consists of two eccentrics *n o* and their rods *p q*, one for the forward and the other for the backward

Fig. 2962.



Link-Motion.

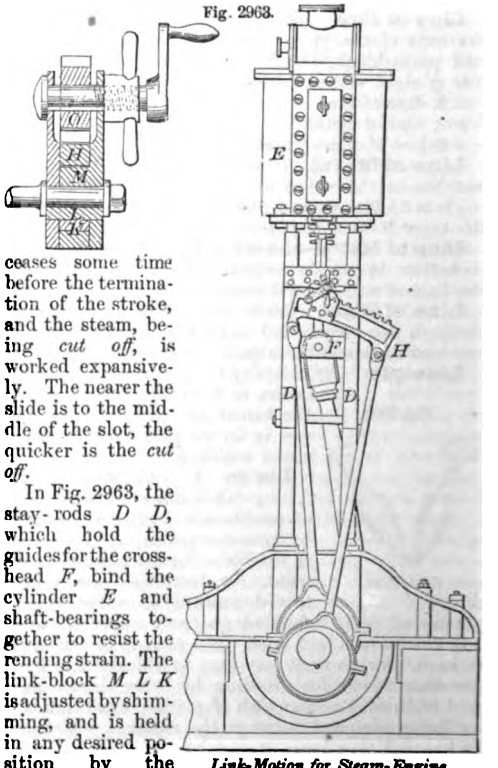
movement of the engine. The rods are connected to the respective ends of a slotted bar *r* called the *link*, which is vertically adjusted by an arrangement of levers terminating in a handle *v*, as shown. The valve-rod *s* is connected to a sliding pin which moves up and down in the slot of the *link* as the latter is adjusted vertically by the handle and connecting-levers previously referred to. The handle is retained at any *set* which may be given to it, by engagement with a notched segment-bar.

The motions of the valve are produced by an impulse imparted to the pin in the slot of the link; as the pin moves, a longitudinal reciprocation is imparted to the valve-rod. The motion of the pin — which is furnished with a slide to adapt it to move in the slot of the link — is made up of the motions imparted to it by the two eccentrics; and when the pin-slide is in the middle of the link, it is not moved at all, as the actions of the eccentrics just balance each other, and the link simply oscillates on the slide-pin as a center. When the link is thus adjusted, the handle being at the middle notch of the segment, the valve is inactive and the engine at rest.

When the slide-pin occupies a position either way from the said middle position in the link, it is thereby brought under the domination of the eccentric-rod, whose end of the link it occupies. The other eccentric-rod then forms a fulcrum, on which the link oscillates, carrying with it the slide-pin, and thereby operating the valve-rod and valve at a *full* stroke. By shifting the link *r* downward from the position shown in the figure, the eccentric *n* and its rod *p* are brought into activity, the rod *q* attaining a *nearly* absolute position, reversing the motion of the slide, and consequently of the engine.

When the slide-pin occupies a position in the link at any point between the middle and either end, it receives a motion therefrom great in proportion to its proximity to the end, and conversely. In such position, the motion of the valve is distinctly made up of the motions of the two eccentrics, as the fulcrum-point of the link is itself shifting, and the effect is to give the valve only a part of the throw of the eccentric. The steam-valves are partially opened, quickly closed again, so that the admission of steam

Fig. 2963.



Link-Motion for Steam-Engine.

ceases some time before the termination of the stroke, and the steam, being *cut off*, is worked expansively. The nearer the slide is to the middle of the slot, the quicker is the *cut off*.

In Fig. 2963, the stay-rods *D D*, which hold the guides for the cross-head *F*, bind the cylinder *E* and shaft-bearings together to resist the rending strain. The link-block *M L K* is adjusted by shimming, and is held in any desired position by the toothed link *H* and the pinion *O*. See Burgh's "Link-Motion and Expansion-Gear." London, 1871.

Digitized by Google

Link-worm'ing. (*Nautical.*) Worming a cable by chains inserted in the interstices of the strands.

Link-le'ver. (*Railroad-engine.*) The reversing lever of a locomotive.

Link-work. Work in which motion is communicated by connecting pieces.

Lin'net-hole. (*Glass.*) (Fr. *lunette.*) A hole connecting the glass-melting furnace with the arch.

Lin'seed-mill. (*Lint*, Flax.) A mill for grinding flax-seed for oil. See OIL-MILL.

Lin'seed-oil. Oil expressed from flax (*lint*) seed.

Lin'sey. (*Fabric.*) A country-made fabric, of linen warp and worsted filling, undressed; hence the name *linsey-woolsey.*

Lin'stock. A *lint-stock.* A gunner's forked staff, to hold a match of lint dipped in a solution of saltpeter. It is referred to by Shakespeare: —

> "And the nimble gunner
> With *linstock* now the devilish cannon touches."
> *Henry V.*

Lint. Raveled or scraped linen reduced to a soft state and used for dressing wounds or ulcers. As formerly prepared, it consisted of scrapings from the surface of old linen cloth, which was drawn beneath a knife, the weft-threads being pushed back from time to time, and the scrapings being obtained from the threads of the warp.

A machine has been used for the purpose, the straight, blunt knife-blade being brought down by a pedal upon the frayed edges of the linen, which lies upon a little leather-covered ledge beneath it. The linen is rolled upon a round stick whose length is in the direction of the weft-threads, and the edge of the piece, being pushed under the descending knife, receives a pull after the knife has supplied it, thereby raveling off the weft-threads and scraping the warp-threads. The art of using the machine consists in causing the knife to descend on the warp between the weft-threads at each descent.

Lint made up into a flat, oval form is termed a *pledget;* into a cylindrical form, or resembling a date-stone, it is a *dossil.*

A substitute for lint consists of carded or scribbed fiber, impregnated with vegetable tar to render it antiseptic and disinfectant.

Lint-doc'tor. A sharp-edged ruler on the delivery side of the calico-printing cylinder, to detain any lint or fibers which may come off the cotton cloth. The *color-doctor* on the other side of the roller acts as a wiper to remove superfluous color. See CALICO-PRINTING.

Lin'tel. (*Carpentry.*) A piece of timber laid horizontally over a doorway or window. An arch above to bear the superincumbent load is called a *discharging*-arch.

Lip. 1. A projecting flange, as on the edge of a kettle.

A narrow surface around an opening, as the *lip* of a bottle.

2. (*Music.*) In organ-pipes, the edge against which the sheet of air impinges. The vibration acquired thereby is communicated to the column of air in the pipe, and produces a musical note. See MOUTH-PIPE; PIPE.

3. (*Water-wheel.*) A rim closing the joint between the barrel and curb of a turbine.

4. (*Vehicles.*) A *cuttoo* plate. A projecting part of the bolster.

Lip-bit. A boring-tool adapted to be used in a brace, and having a cutting lip projecting beyond the end of the barrel. See BIT.

Lip-head Bolt. A bolt with a head projecting sideways.

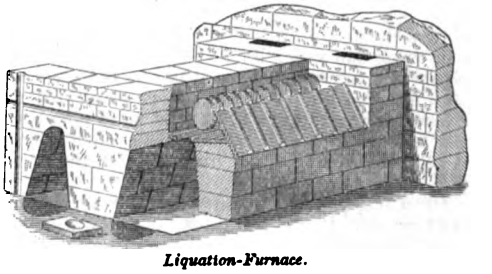
Li-qua'tion. Silver is separated from copper by melting the alloy with the addition of lead, and cooling the triple alloy suddenly in the form of cakes. These cakes are heated to such a degree on an inclined hearth as to cause the alloy of lead and silver to run off, and allow the copper to remain.

The lead and silver may be separated by cupellation or by Pattinson's process, in which the alloy is allowed to cool slowly and the crystals removed as they form, leaving the alloy relatively richer in silver. By a repetition of the process an alloy of great richness is procured, and the operation may be followed by cupellation, in which the lead is oxidized, melts, and runs off. See LEAD-FURNACE.

Li-qua'tion Hearth or Fur'nace. A hearth or furnace in which metals are separated by exposure to a heat which melts one or more of them, but leaves the other or others unmelted.

The disks of alloy — say, copper, lead, and silver — are set on edge in a slanting position on two iron plates, between which is an interval. Wedges are placed between the disks until the furnace is charged, and the space around the disks is then filled in with

Fig. 2964.

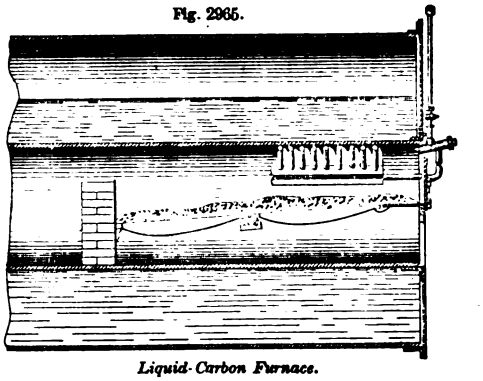


Liquation-Furnace.

charcoal, the top of the furnace restored, and heat applied to the kindling in the chamber below. As the temperature increases, the alloy of lead and silver, whose union is more intimate than that of either with the copper, becomes fused and runs down to a conductor on the bottom of the fire-chamber, and is led to the cistern in front, from whence it is ladled, the lead and silver being afterward separated by cupellation.

Liq'uid-car'bon Fur'nace. A furnace in which liquid fuel, such as petroleum, is introduced into the fire-chamber and burnt in contact with air and sometimes with steam. The example has an injector above the fire-door, for the introduction of the liquid hydrocarbon; the supply is regulated by a cock, and

Fig. 2965.



Liquid-Carbon Furnace.

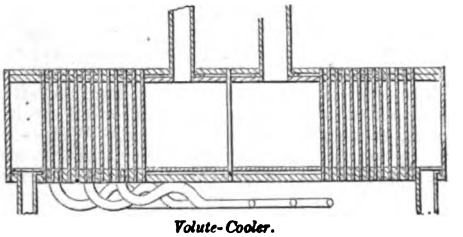
Digitized by Google

at the point of ejection it is associated with superheated steam at a temperature of about 600° Fah. The combined spray thus injected comes in contact with the hot ashes on the grate-bars, by which it is ignited.

In raising steam, fire is first made on the grate-bars in the ordinary way, and the injector is brought into action when the required pressure is obtained in the boiler.

Liq'uid-cool'er. An apparatus for cooling wort, beer, wine, water, etc. On a small scale, as the wine-cooler at the sideboard, it is a tub in which

Fig. 2966.



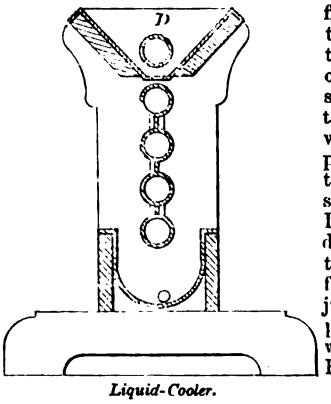
Volute-Cooler.

bottles are stood with broken ice around them. For soda-water and other liquids on draft, it is a coil of pipe which passes through a chamber, and is covered with pounded ice. For milk, it is a pan which has a false bottom, through which cold water circulates. For beer on draft, it is a chamber in which the keg is set with blocks of ice about it and the faucet projecting. See Fig. 632.

On a larger scale, used in breweries for cooling wort or beer, it has many forms. It is usually a very large shallow vat. One is shown in Fig. 2966. It is a volute, formed by a wide strip of metal set on edge between upper and lower heads. A long sheet-metal plate is folded and then convolved, so as to form a helix with two distinct spaces; the edges of the plate are attached to the top and bottom disks, which form heads, and one space in the convolution is for the refrigerating liquid, the other for the vapor or fluid to be condensed; induction and eduction passages admit and discharge the respective fluids.

In Fig. 2967, the beer, on its way from the *cool-beds* to the fermenting-tun, flows into the trough *D*, and thence trickles over the vertical series of horizontal pipes, through which cold water passes. Similar to this in construction is the Degrand condenser, except that the latter is for heating cane juice, and the pipes are filled with steam. See Fig. 1421.

Fig. 2967.

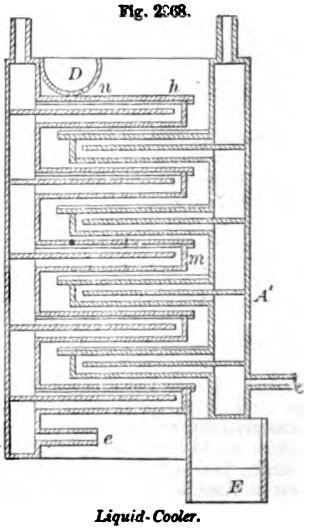


Liquid-Cooler.

The cooler in which the wort passes through a coil of pipe in a vat which is filled with ice, or through which flows a stream of cold water, is also like the coil-condenser in the arrangement of its parts. See Fig. 631.

Another form is that in which an outer and an inner vessel are filled with ice and communicate by short tubes which cross the intervening space; over these tubes the beer descends in a shower from a pan above.

Fig. 2968.



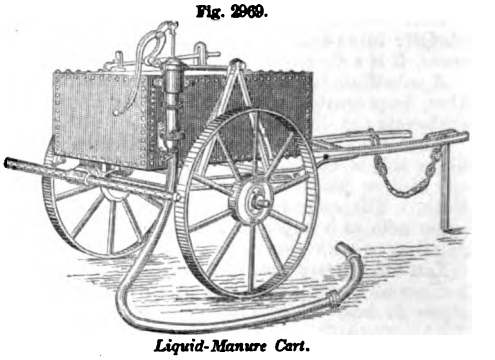
Liquid-Cooler.

Fig. 2968 has two vertical cases *A A'* in which wort circulates, discharging at *e* and *e'*. From each of these cases project boxes *h m*, which lap past each other in the intervening space through which water flows from *D* to *E*. In the cases are also plates which extend into the boxes, so as to form a sinuous channel through which the wort passes in a sheet against the outer walls of the box, which are cooled by the water.

Another form is a series of inclined troughs through which the wort passes to be cooled by exposure to the air.

Liq'uid-ma-nure' Cart. A tank on wheels for conveyance of liquid manure to a field and distributing it there. As shown, it is made of boiler-iron riveted, and is filled by means of a portable pump

Fig. 2969.



Liquid-Manure Cart.

and hose, shown in position. The tank is hung upon centers, so as to remain level on inclined ground.

Liq'uid-me'ter. A device for ascertaining the quantity of liquid received or discharged through an orifice. See METER, WATER.

It does not appear to have been in use prior to 1824, when William Pontifex of London, England, patented a new mode of adjusting or equalizing the pressure of fluids or liquids in pipes or tubes, and also an improved mode of measuring said fluids or liquids. This consisted in forming a chamber over the supply-pipe and near its end, in which was a leathern cup secured to the top of the chamber. A series of weights, one above the other, was also suspended from the top of the chamber, which were successively raised as the pressure of the liquid increased. An arm connected with the bottom of the

Digitized by Google

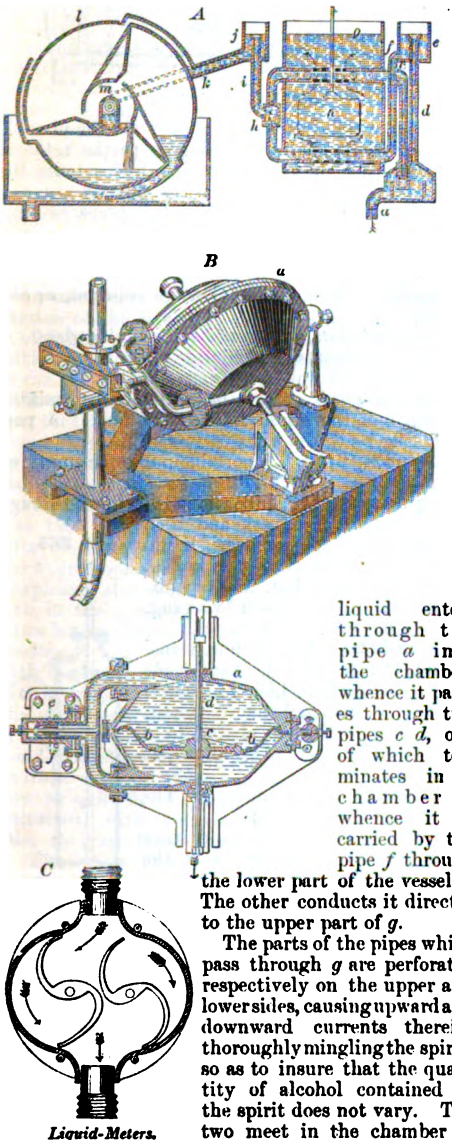
cup operated a valve, which gradually closed the discharge orifice as the weights were lifted.

William Brunton, near the same time, invented a meter in which the reciprocating motion of a piston in a cylinder was caused to measure the amount of water discharged, the valve arrangements, etc., being similar to those of the steam-engine.

The forms of meter are various, the principal being known as the *diaphragm*, the *balanced*, in which compressed air is employed, the *piston*, the *propeller*, and the *flexible tube and roller* meter.

The spirit-meter of Siemens and Halske is shown in Fig. 2970 (*A*). This instrument is designed to register the quantity of spirit discharged, and also the amount of absolute alcohol contained therein. The

Fig. 2970.



Liquid-Meters.

liquid enters through the pipe *a* into the chamber, whence it passes through two pipes *c d*, one of which terminates in a chamber *e*, whence it is carried by the pipe *f* through the lower part of the vessel *g*. The other conducts it directly to the upper part of *g*.

The parts of the pipes which pass through *g* are perforated respectively on the upper and lower sides, causing upward and downward currents therein, thoroughly mingling the spirit, so as to insure that the quantity of alcohol contained in the spirit does not vary. The two meet in the chamber *h*, passing through a pipe *i* into a chamber *j*, from which it flows into the *volumeter* through the pipe *k*. The volumeter is a hollow drum *l*, having a concentric cylinder *m*, the space between the two being divided into three compartments. Three slits in the central cylinder permit the liquid to flow successively into each compartment, as it in turn occupies the lowest position. The openings are so arranged that while the lower chamber is filling the level is too low to permit an escape into either of the others, and the apparatus remains stationary until the lower chamber is full. The discharge of this then commences, while the aperture through which it received its supply is carried by the rotation above the liquid in the central chamber. To prevent overflow until this change of position has occurred, the discharge-channels are carried spirally from each chamber round the exterior of the one next following. The registering dials are actuated in the usual manner. The amount of pure spirit is determined by the indications of a hydrometer *n* in the tank *g*, having a curved lever, the shorter arm of which is connected with its stem. The hydrometer is filled with alcohol, and rises and falls according to the density of the surrounding spirit, causing the lever to vibrate each time that a chamber of the volumeter is emptied, to an extent indicating the quantity of pure spirit contained therein. A three-leaved cam, attached to the axis of the volumeter, is connected with the long arm of the lever, and is provided with a ratchet-wheel of large diameter with fine teeth. This is placed on the axis of the first register-wheel, and causes it to turn an amount equal to the movement of the curved lever.

The water-meter of Duboys of Paris (*B*) consists of a casing *a*, in the interior of which is a diaphragm *b*, carrying in its center a metallic disk *c*, the convex edges of which accurately fit the sides of the casing. The diaphragm and disk are kept in position by the rod *d*, which passes through water-tight orifices. *e* and *f* are apertures for receiving and discharging the water.

As the water enters through either duct, as *e*, it raises the diaphragm, forcing out the water on the upper side until the vessel is full, when the diaphragm fits closely against that side. During the process of filling, the vessel is inclined; but when the weight rises to the top, it gives that side the preponderance, causing the vessel to turn on its pivots until it becomes the bottom side. At the same time, the supply-opening is closed and that for discharge opened, while on the opposite side a contrary effect is produced. Arrangements are provided to prevent the vessel from tilting until it is entirely filled.

The meter of M. Clement of Orleans consists of an upright cylinder divided into five compartments, each of which is caused to actuate a crank on a vertical axis common to all. This carries a compound stop-cock, which admits the water to and discharges it from each compartment when filled.

Payton's meter (*C*, Fig. 2970) contains two S-shaped arms, whose extremities during rotation are in close contact with each other and with the sides of the box. The arrows indicate the direction of the current. Similar devices are shown under ROTARY BLOWER; ROTARY PUMP.

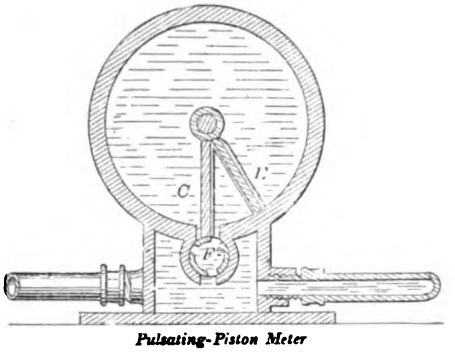
In Cochrane's meter for measuring liquids under pressure, the measurement is effected by a pivoted vessel resembling a double scoop, which tilts and discharges when either side is full. A bent lever below this is tilted back and forth at each movement of the scoop, actuating the registering mechanism.

Atwell's cylindrical case has a piston *E* which turns on an axial shaft communicating motion to the register, and carrying an arm which, at the end

Digitized by Google

of each stroke, changes a cylindrical valve F^2 so as to cause the water to alternately enter and discharge

Fig. 2971.



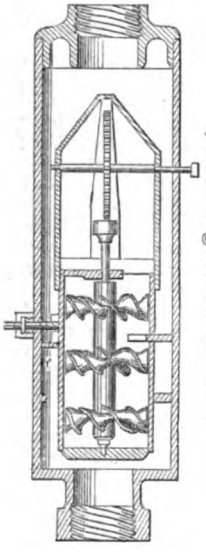
Pulsating-Piston Meter

from the measuring-chamber at opposite sides of the internal partition *C*.

In Fig. 2972, a water-wheel within a pipe is connected to a register to indicate the flow of water. The flow is regulated by a sliding-valve.

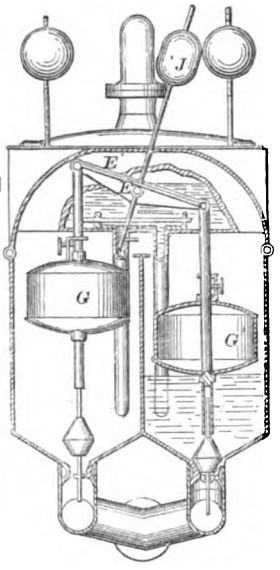
In Young's spirit-meter, floats *G* in the measuring-chambers are attached to each end of a pivoted beam. The alternate downward motion of the floats, as the chambers are discharged, diverts the induction flow from one to the other. The floats *G* and their valves occupy two chambers, and are suspended to opposite ends of the oscillating beam *E*. The valve-stems have a limited sliding motion in the

Fig. 2972.



Spiral-Vane Meter.

Fig. 2973.

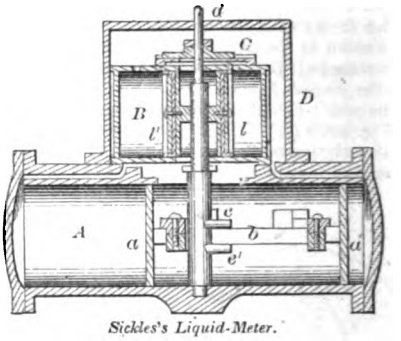


Young's Spirit-Meter.

floats, so that the float will rise to a sufficient hight without raising the valve to permit the emptying of the chamber. At the point of discharge the weighted rod *J* is thrown past the vertical, and, closing the valve to this chamber, opens the induction-pipe to the other chamber, depressing that float sufficiently to close the escape-valve.

In Sickles's meter (Fig. 2974) the liquid, flowing into the chamber *D*, is by means of the valve *C* admitted alternately to each end of the hollow valve *B*, which is divided into compartments by the partitions *l l'*. From these the fluid flows alternately through appropriate ports behind the pistons *a a'* on

Fig. 2974.



Sickles's Liquid-Meter.

the rod *b*, which has tappets that strike the pins *e e'* on the upright shaft *d*, causing its partial rotation and operating the slide-valve *C*, which admits the fluid into the compartments of the valve *B*.

Liq'uor. 1. A term applied to a prepared solution, as, —

(*Sugar.*) A solution of sugar, used in claying the loaves.

(*Dyeing.*) A dye or mordant in solution, as *tin-liquor*.

Liquor of flints, liquor silicum; soluble glass.

Liquor of libavius; bichloride of tin.

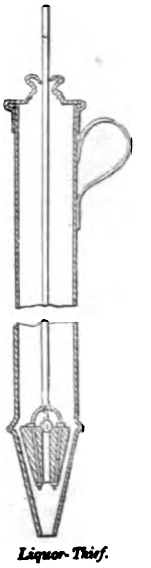
2. A dilution; as *liquor ammonia*, etc.

Liq'uor-gage. A measuring-rod for determining the depth of the liquid in a cask or tank. A part of the gager's equipment.

Liq'uor-pump. A portable pump for emptying casks, etc. See BURR-PUMP.

Liq'uor-thief. A tube which is let down through the bung-hole of a cask and then closed, so as to withdraw liquid therefrom. It is usually closed at top by the finger, but, in the illustration, the tube is closed by a plug. A *sampling-tube*. A *velinche*.

Fig. 2975



Liquor-Thief.

Lisle-lace. A light, fine, transparent, white-thread, hand-made lace, so called from Lisle in France. It has a diamond-shaped mesh, formed by 2 threads plaited to a perpendicular line. Also known as *clear-foundation*.

Lis'sens. (*Rope-making.*) The ultimate strands of a rope.

List. 1. To chop a block or stave to an approximate shape; e. g. the balk or *codling* from which staves are to be rived is chopped to give a taper towards each end, before being cleft into staves by the *frow* and mallet.

2. (*Carpentry.*) *a.* The upper rail of a railing.

b. A narrow strip from the edge of a plank.

c. A small, square molding. A *fillet*.

3. A selvage (*self-edge*) strip on the edge of broadcloth.

4. (*Rope-making.*) A woolen flap in the hands of a rope-maker, through which the yarn goes.

Digitized by Google

5. *a.* A thin coat of tin preparatory to the thicker coat, in tinning iron plates.

b. A selvage or wire of tin formed on the under edge of plates in tinning.

6. (*Nautical.*) An inclination of a ship to one side. A *heel.*

List'el. (*Joinery.*) A narrow, slightly projecting ledge. A *reglet.*

List'er. A three-pronged fish-spear. See LEISTER.

List'ing. 1. Cutting away the sappy edge of a board.

2. The narrow edge of a board.

List-pan. (*Tin-plate manufacture.*) A perforated skimmer.

List-pot. A heated pan with a small quantity of tin at the bottom, and the last of the series of five pans used in the manufacture of tin-plate. *Tin-pot, wash-pot, grease-pot, pan, list-pot.* See TIN-PLATE.

Lith'arge. Semi-crystalline or fused protoxide of lead, obtained in separating silver from lead ore, and used in the composition of flint-glass.

Lith'ic Paint. A mastic of petalite (which contains an alkali known as lithia), sand, and litharge, used as a coating for walls.

Lith'i-um. A metal, the base of lithia.

Equivalent, 6.9; symbol, *Li.* This rare metal somewhat resembles sodium, and has no special interest in a mechanical point of view. Specific gravity, 0.59; fusing-point, 356° Fah.

Lith'o-clast. (*Surgery.*) A powerful forceps-like instrument, with two blades having concealed chisel or wedge shaped projections to cut the stone in the bladder into pieces, if found to be too large to extract by means of the lithotomy-forceps after the operation of lithotomy.

Lith'o-col'la. A cement for uniting stones. See CEMENT.

Lith'o-frac'teur. Composed of nitro-glycerine, 52 per cent; infusorial silica and sand, 30 per cent; carbon, 12 per cent; $NaO\ NO^5$, 4 per cent; sulphur, 2 per cent.

Its characteristics, as compared with dynamite, are: (1) greater sensitiveness to temperature, exploding at 120°, while dynamite explodes at 190°; (2) greater sensitiveness to moisture from the presence of the hygroscopic nitrate of soda; (3) the gases from the explosion always contain carbonic oxide from the carbon in the compound; (4) for equal volumes it has the less explosive power. — *Journal of Applied Chemistry.*

Lith'o-glyph. An engraving on a gem.

Lith'o-graph'ic Cray'on. In drawing on stone for the purposes of lithographic printing, crayons are used. They are composed essentially of soap, wax, fat, and lampblack, and are cast in the form of little cylindrical sticks. These are fastened in a porte-crayon or quill in the ordinary way. The above constituents, with various additions of shellac, mastic, etc., are fused together and finally set on fire. The longer the mixture burns, the harder the product becomes; three or four grades are usually made.

A grained lithographic stone is always required for a crayon-drawing; that is, a stone to which an evenly roughened surface has been given by grinding it carefully with sharp sand of a uniform character. The asperities upon the surface of such a stone remove the substance of the crayon in quantity proportionate to the pressure employed by the artist. When finished, such a drawing appears to the eye exactly as the impressions on paper printed from the same stone are intended to look. The printing capability is possessed by a crayon-drawing only after it has been etched with a very weak acid and gum-water. See LITHOGRAPHY.

Lithographic crayon or chalk (Engelmann):—

Yellow wax, 32 parts; Marseilles soap, 24 parts; tallow, 4 parts; saltpeter, 1 part; lampblack, 7 parts.

Melt the wax and tallow first; add the soap gradually, and heat till the mixture catches fire of itself. Remove the vessel from the fire, and let its contents burn for about two minutes for soft, and three minutes for hard, crayons. Extinguish the flame, and add very gradually and carefully the saltpeter dissolved in 7 parts of water. Heat is now to be applied with constant agitation, till the mass again takes fire, when it is to be instantly extinguished and the lampblack added. Mix very thoroughly, and heat till combustion once more takes place, which is to be instantly checked as before. It now remains to test the quality of the crayon as to hardness, and the quality of the point which can be given to it. A sample is poured out for this purpose, cooled, cut into strips, and left standing a day. If soft, farther burning will harden the product; but it can only be softened by adding an extra soft quality of crayon. When satisfactory, the mass is melted and poured into suitable molds. There are many other recipes for making crayons, involving the use of resins, etc., but the above is the simplest, and without doubt one of the best. Lemercier's formula is but a rehash of the foregoing, and the same may be said of Korn's, save that he does not set fire to his mixture, but prolongs the time of melting immensely, to attain the hardening of the mass.

Lith'o-graph'ic Ink. Lithographic ink, adapted for drawing on stone, is a compound similar to that used for LITHOGRAPHIC CRAYONS (which see), save that soap enough is present to render it quite soluble in water. It is rubbed up like india-ink, and used with a pen or very small hair-pencil, mostly on smooth stones. The usual preparation with acid and gum-water fits the work done with it for printing.

The same, or an ink quite like this, is also used for writing on *autographic transfer-paper.*

Transfer-ink is used for transferring from one stone to another, or from an engraved plate to stone, also for photo-lithographic transfers. It is composed of fatty and resinous bodies fused together, and often burned. Soap is frequently added in small quantity, and it is always colored with lampblack. Transfer-ink is used with a roller, like printing-ink, or with a *tampon* or pad, when transfers are made from engraved stones. This ink is sometimes called re-transfer-ink, in allusion to the fact that the printing surface is sometimes formed by a second transfer.

Printing-ink for lithographic purposes is very similar to that used by the type or woodcut printer. In the latter, boiled oil, resin-oil, and similar adhesive fluids serve as a vehicle for the carbonaceous or mineral matter which gives the color. In lithographic printing, the nature of the oily substance ground with the lampblack, or color, is all important; for upon its affinity for the design upon the stone, and its repulsion for the damp portions, depends the possibility of printing. Experience has shown that *burned linseed-oil*, technically known as LITHOGRAPHIC VARNISH (which see), is admirably adapted for the manufacture and thinning of lithographic ink. The treatment such varnish has been subjected to, while it does not seriously lower its affinity for the lithographic picture, or its repulsion for the gummed and damp parts of the stone, will be found to have deprived it completely of its greasy character, which would gradually tend to smear and cloud the work.

In the manufacture of black ink, the quality de-

Digitized by Google

pends a good deal upon that of the lampblack used; but chiefly upon the thoroughness of the mechanical process by which it is ground. It comes into the market as an exceedingly tough paste, made up in closed cans. The lithographic printer thins this with varnish of appropriate consistence, to suit his requirements, using the muller and pallet-knife to make the mixture thorough and uniform.

Recipes for a variety of lithographic inks are appended hereto.

Lithographic ink for drawing and writing on stone with the pen (Desmadryll, Sr.): White wax, 40 parts; mastic, 10 parts; shellac, 28 parts; white soap, 22 parts; lampblack, 9 parts.

The wax is heated in a suitable vessel till it continues to burn when set fire to. It is then removed from the fire, and the soap, shellac, and mastic added in small quantities at a time, but not fast enough to extinguish the flame. When all the ingredients are mixed, the cover is put on the pan, so as to stop farther combustion; the lampblack is now added, and the whole heated once more till it catches fire; the flame is extinguished at once, and the ink is examined after cooling. If it gives a solution which too soon becomes gelatinous or sticky, it must be burned more.

Another recipe, which gives a softer ink, is the following (Desmadryll, Sr.): Tallow, 10 parts; wax, 10 parts; soap, 16 parts; shellac, 14 parts; lampblack, 5 parts.

Fuse together and treat exactly as above.

The following is Lemercier's recipe for a similar ink: —

Yellow wax, 4 parts; tallow, 3 parts; white Marseilles soap, 13 parts, shellac, 6 parts; lampblack, 3 parts. Melt the wax and tallow, and add the soap in small quantities, then the shellac, and stir till all is evenly blended. Raise the temperature till the vapors take fire, burn cautiously for from one to two minutes; the lampblack is to be added next, and well mixed, and heat continued for a quarter of an hour. The ink is then poured out on a slab, cooled, and again melted with moderate heat, and constant stirring. The second melting is supposed to effect a more thorough blending of the constituents.

Ink for working on stone with the hair-pencil (Engelmann): —

Wax, 6 parts; soap, 6 parts; tallow, 3 parts; lampblack, 2 parts. Melt together and burn for a short time.

Ink for autographic transfer (Engelmann): —

Shellac, 16 parts; white wax, 10 parts; soap, 8 parts; dragon's blood, 8 parts; tallow, 5 parts. Melt the wax and tallow till ready to take fire; add the soap gradually in small pieces, and let the heat rise to the point of combustion. Add, while burning, the shellac and dragon's blood, and continue the burning for about five minutes. One part of this mixture dissolved in eight parts of hot water gives a good ink.

Another recipe (Cruzel) is as follows: —

White wax, 8 parts; white soap, 2 parts; shellac, 2 parts; lampblack, quantity sufficient. Melt the soap and wax together, then add the lampblack, of which there should be no more than will just color the ink when dissolved. Burn for about half a minute, put out the flame, and add the shellac with constant stirring. Heat is again applied till the mixture takes fire, after which it is cooled.

Mantoux obtained the gold medal from the *Société d'Encouragement*, for the following autographic ink: —

Gum-copal, 6 parts; wax, 10 parts; tallow, 10 parts; soap, 8 parts; shellac, 10 parts; gum-mastic, 10 parts; sulphur, 1 part. Heat the copal till it begins to crackle; then, to facilitate its fusion, add a small quantity of olive-oil. When melted add the tallow and wax. Heat and ignite, and add the soap quite dry and in little pieces. When melted and while still burning, throw in the mastic and shellac. The sulphur is now stirred in, whereby the heat will be increased, and the union of the copal with the other ingredients accomplished thoroughly. The flame at this stage of the process is to be extinguished, but after cooling a little the whole is again heated, and set fire to, and let burn moderately till the volume of the whole is reduced to one fourth of what it was. This ink is to be dissolved in ten parts of hot water; it is difficult to make, but is said to be one of the very best.

Ink for transfer from stone to stone: —

Wax, 1 part; soap, 1 part; tallow, 1 part; varnish, 4 parts; Venice turpentine, 6 parts; stiff printing-ink, quantity sufficient.

These substances are melted, and thoroughly mixed with the muller on a slab slightly warmed, the proportion of printing-ink being kept as small as possible. If too thick for use, more varnish is added by the printer, according to his judgment, at the time of pulling the transfer-sheet.

The above recipe can only be regarded as typical of and one of the simplest of the infinite variety of compounds for transfer from pen and crayon drawings on stone, and also from engraved stones and plates. It may almost be maintained that there are as many formulas for transfer-inks of this kind as there are transferrers, each making his own favorite compound, often with imposing secrecy. As in many other cases, marked success in transferring depends more upon the man than upon any other single circumstance.

Lith'o-graph'ic Pa'per. For transfer purposes, Chinese paper (India proof) is much used. It is cut into large sheets, and prepared by coating one side evenly with starch-paste, applied with a sponge. When dry, a second coat is sometimes given. Such paper is used for transferring from stone to stone.

For autographic transfers, any good book or writing paper may be employed. The sizing on the latter is often considered sufficient, but for first-class work a coating of a solution of isinglass or gelatine, with an addition of gamboge, is generally used. For photo-lithographic transfers, *Saxe* paper is required to attain superior results.

For printing from lithographic stones, almost any paper is suitable which is fitted for type and wood-cut work. This is not so when a soluble chemical substance is present in the paper, such as chlorine, alum, etc. The fact that the stone is constantly wet causes such re-agents as the above to act upon it, and upon the drawing which takes the ink, even when the paper itself is not dampened, and a gradual but certain deterioration of the work necessarily follows. In the early days of lithography, when paper was made for mechanical printing processes only, difficulties were experienced in procuring it of suitable quality for lithographic printing. These difficulties no longer exist, manufacturers having much improved the bleaching and sizing of stock. Unsized paper, such as India proof and plate paper, usually printed damp, generally give the clearest and blackest impressions from stone. For crayon and close artistic work, one or the other is indispensable; but they are expensive and will not stand wear and tear, therefore sized papers of various kinds and qualities, as book, map, bond, are largely employed for commercial and professional work. On the lithographic power-press, paper more or less

Digitized by Google

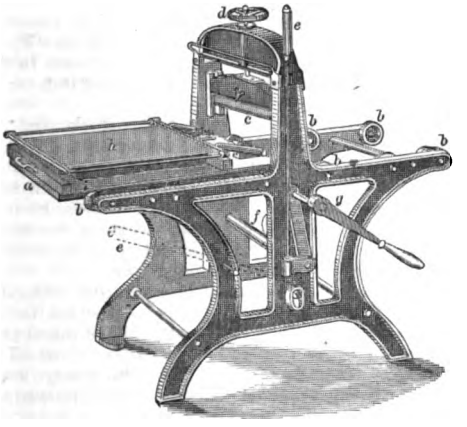
sized works better than that in which the fibers are easily disintegrated. On such presses dry paper is very desirable, therefore much attention is now being paid to smoothness and regularity of surface, which should lift the ink thoroughly without injuring the work, even on editions of many thousands from the same stone. Such papers are now manufactured, although greater perfection in this respect is still desirable, the power-press having created a demand for quality as well as quantity not dreamed of ten years ago.

Lith'o-graph'ic Pen. (*Lithography.*) Lithographic pens for writing on stone are now made by the best steel-pen makers, and are used to a limited extent. Such pens are exceedingly small and fine, even finer than a crow-quill, but the best lithographic pens are yet made by the artists themselves. They are made of thin steel ribbon, very slightly hollow, shaped and slit by a fine pair of scissors made specially for the purpose. These pens are not fitted for working on paper, but on the surface of the stone they give lines of extreme fineness unattainable in any other way.

Lith'o-graph'ic Press. The manner of applying pressure to a lithographic stone for the purposes of printing or transferring differs essentially from that employed for analogous work in the type and copperplate hand-presses. In the latter two, up and down pressure of the platen, or the progressive rolling pressure of the cylinder, is employed; in the former, a scraper is used. In power-press printing, however, it will be seen that these distinctions do not hold good.

The lithographic hand-press consists of a frame provided with rollers *b b b*, on which the carriage *a*

Fig. 2976.



Lithographic Hand-Press.

runs to and fro. The scraper *c* consists of a flat piece of boxwood, beveled from both sides to about a quarter-inch edge, and firmly clamped in the sliding iron piece above. The hight of the scraper above the carriage can be adjusted by the screw *d* to suit the varying thickness of the stones. The manner of printing is as follows: The stone *i*, with the design upon it, is placed face up upon the carriage; it is damped and inked, and the sheet of paper which is to receive the impression is laid thereon. The tympan *h* of leather, stretched in an iron frame, is then lowered upon it, as in the figure, and the carriage pushed under the scraper. By depressing the lever *e* to the position indicated by the dotted lines, the toggles at each end of the shaft *f* raise the bearings of the winch *g*, upon the axle of which a strong iron roller is made fast. This roller, or cylinder, is the full width of the press, and the depression of the lever brings it into contact with the under side of the carriage, lifting the latter at the same time off the rollers *b b b*, and pressing the forward end of the stone against the edge of the scraper. By revolving the winch-handle, the stone is slowly dragged under this stationary edge, which applies its pressure progressively through the leather of the tympan, to a narrow strip of the work, the result being equivalent to a very much greater crushing force applied over a larger surface. When the whole of the design has passed under the scraper, the lever *e* at the side is restored to its upright position, the carriage falls upon the rollers *b b b*, it is brought back by hand, the tympan lifted, and the printed sheet removed.

This, with unimportant modifications, is the form given to the lithographic hand-press in England and America. In Germany, Belgium, and France, presses of this construction are rarely seen. In Prussia, for instance, a press is used, occupying nearly double the space, but admirably constructed and well adapted for the execution of first-class work. In this machine, the scraper and its holder swing from the side across the carriage, the holder or *head* is then locked, and the pressure applied by a compound lever with the foot. The carriage is then drawn through by a broad girth or belt, one end of which is made fast to it and the other wound about an axle of small diameter at the extreme end of the frame, rotated by a *star* similar to that of a copperplate-press. The result is an exceedingly steady and uniform motion, but the loss of time as compared with the English press is considerable.

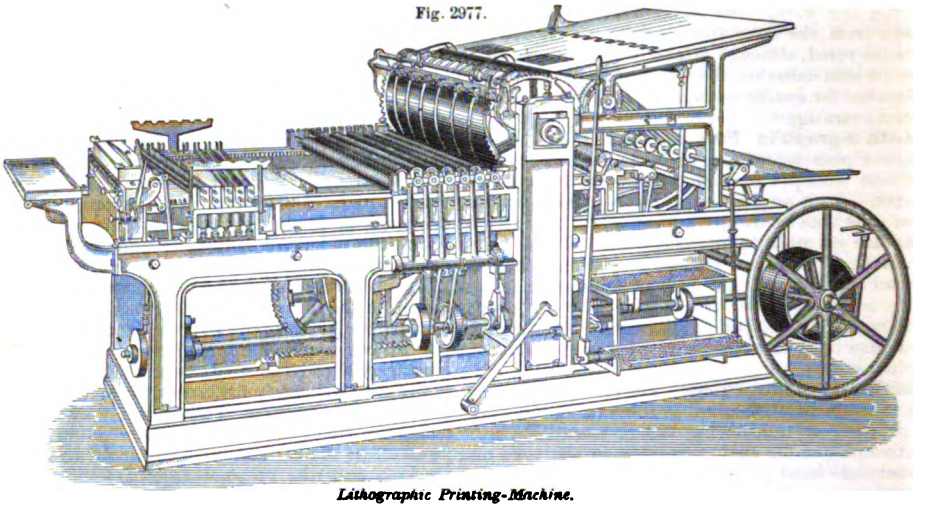
In the construction of lithographic power-presses, the scraper principle has been tried without success; power has long been and is still applied to the ordinary hand-presses, to relieve the workmen from the labor of pulling the carriage through; but for all automatic presses driven by steam, a cylinder of large diameter is now employed to apply the pressure. Since 1865, many press-builders in Europe and America have turned their attention actively to this subject, and produced serviceable machines. One of the most satisfactory presses of the kind, though not the earliest, is that now well known as Hoe's Steam Lithographic Machine. It is a stop-cylinder press, or one in which the cylinder comes to rest pending the adjustment of the sheet. The paper is fed to grippers on the cylinder from the inclined table above. The traveling-bed, on which the stone rests, is drawn under the cylinder by a crank and connecting-rod from the end of the frame below, and the cylinder, after being thrown into gear, is rotated at the same time (carrying the sheet with it) by a rack attached to the side of the bed. At the end of the stroke the cylinder goes out of gear, and remains stationary and locked during the return of the bed and stone; the latter passing under a cut-away part of the cylinder, so as not to come in contact with it. In place of a tympan, the cylinder is covered with a thin rubber blanket. The inking of the stone is effected by parallel rollers (from three to six) in front of the cylinder, upon which are heavy riding rollers of iron; the latter being made to vibrate laterally to aid the distribution of the ink. These inking-rollers are covered with leather, like the ordinary hand-rollers for lithographic printing; they receive their ink from a table which travels with the bed, and are driven by a rack or friction-pieces on the sides of the bed. The ink is fed to said table from a fountain at the end of

Digitized by Google

the press, and distributed by a number of oblique-lying rollers, also covered with leather.

The automatic damping arrangement is at the back of the cylinder. It consists of a shallow trough containing water, partially immersed in which a cylinder of wood is made slowly to revolve. An absorbent roller is held in contact with the wet surface of this cylinder for a longer or shorter time, accord-

Fig. 2977.



Lithographic Printing-Machine.

ing to the amount of water required upon the stone, after which it carries its increase of moisture over to a heavy riding-roller, which again gives it up to two damping-rollers covered with linen, which traverse the stone as it passes beneath them, just before it meets the inking-rollers at the other side of the cylinder; the feed of water admits of adjustment as to quantity, while the press is in motion.

The pressure in this press is adjusted by means of butting-screws, which lift or lower the bed in the traveling-carriage; these screws are turned by a key from above.

When the sheet is printed it is conveyed by an intermediate cylinder provided with grippers to the fly at the end of the press, and there deposited, face up, on the pile of printed work.

This press, though by no means identical with European machines of the same class, may be regarded as furnishing an illustration of the essential features of them all.

The introduction of the lithographic power-press has totally remodeled the lithographic trade throughout the world within the short period of four years (from 1868–72), increasing the possible production about tenfold. It has lowered the cost of, and, in fact, rendered possible, large editions from stone, which, in former times, found their way to the type-press with very inferior results. By this change the general public have profited largely.

Lith'o-graph'ic Roll'er. (*Lithography.*) Made of a stock of wood or metal, covered with a fold or two of woolen cloth, over which a *skin* of leather is drawn. The leather is of fine quality and shaved to an even thickness. The seam is made by turning the leather edge to edge and sewing it with silk, it being afterwards turned inside out. The *grain* or *hair* side of the leather is generally used for color-rollers, for the reason that it can be washed with turpentine, and for no other reason. Where a roller is kept for each individual color, as at Prang's chromo establishment, the flesh side is used for this as well as for black printing.

Hand-rollers are from 11 to 14 inches in length and 3½ inches in diameter. They have timber stocks for lightness, and the handles at the end are laid hold of by loose leather sleeves, in which the handles turn, and by compressing which, the printer, without blistering his hands, can produce a variety of effects. By a slow motion, with considerable pressure, the roller drags over the stone, depositing ink; by a quick motion and light pressure the tendency is to lift ink. In like manner the roller of close-grained leather deposits ink, while the tendency of a coarser grain of leather is to lift it. These considerations are of the greatest importance in developing the resources of the art of printing, for in this case it is an art.

Machine-rollers have a metallic stock, but in other respects are made as the hand-rollers. The expense of making them is much increased by the great length, which is sometimes as much as 50 inches. The improved method is now to drive them by friction disks running with the bed, whereby the speed of the rollers is rendered equal to that of the surface of the stone, preventing wiping action.

The capacity of a lithographic-printing roller depends upon the relative adhesion of the ink to the leather surface of the roller, and to the inked surface of the stone.

Lith'o-graph'ic Stone. A sedimentary limestone from the upper beds of the Jurassic formation. Lithographic stones of various sizes and weights are now articles of commerce all over the world. They are obtained almost solely from the extensive quarries of Solenhofen, in Bavaria. France furnishes a very hard and dark blue stone, which is but little used. In Canada stone of good quality is said to exist, as also in Missouri; but little is known of either. The Bavarian stone occurs in nearly horizontal layers. When these are of suitable quality and thickness (from two to five inches), they are squared and trimmed for exportation, the slabs varying in size from 6 × 8 to 40 × 60 inches. Two qualities are recognized: the yellow, and the blue or gray (though the difference in color is not much). The latter are harder and more generally serviceable, and cost ten to fifteen per cent more than the yellow.

Digitized by Google

Lithographic stone is a very homogeneous substance, free from sand or grit, and possessed also of strength sufficient to stand the wear and tear of the press. Besides carbonate of lime, it contains small quantities of magnesia and alumina, and traces of silica and iron. Its serviceableness for lithographic purposes depends chiefly upon its chemical constitution, in which respect it may be regarded as carbonate of lime only.

In this country, lithographic stones are sold by the pound, and the ratio increases rapidly with the size, varying from five to twenty-five cents. Zinc plates are used successfully as a substitute for stone, but they are by no means so generally useful. See LITHOGRAPHY and ZINCOGRAPHY. See also list of processes under FINE ARTS; ENGRAVING; 'GRAPH.

Lith'o-graph'ic Var'nish. An oily varnish used for the manufacture of lithographic ink, and by printers for thinning the same. It is made by heating linseed-oil very strongly in a suitable pan, and finally setting fire to it. When sufficiently changed in its nature, and sufficiently concentrated, the flame is extinguished by a cover, and the varnish let cool. The changes which take place during this treatment of the oil are not well understood. All the older recipes insist on the introduction of several slices of stale bread, and some peeled onions, into the oil when it gets hot. Their effect has been variously stated; but, beyond a great commotion and consequent exposure of the surface to the air, their beneficial action is more than problematical. When the oil has become hot enough to take fire, it is let burn under proper control, by which treatment a considerable diminution of its bulk is caused and an increase of its viscidity. The longer it burns the stiffer and more sticky it becomes, drawing out into threads between the finger and thumb. In this respect, there are three or four grades known to the trade, as Nos. 1, 2, 3, 4.

Lithographic varnish is not to be confounded with *boiled linseed-oil*, in the preparation of which oxide of lead is used. It retains enough of the greasy character to impart to the ink the qualities requisite for lithographic printing, but not enough to smear the stone or grease the printing-paper. It may tend to elucidate the changes which fatty bodies undergo when strongly heated and burned, if it is remembered that previous to combustion the oxygen of the air comes in contact with the hot surface; but that after the fused contents of a pan are covered with a flame, there can be no more oxidizing action, only a species of concentration or elimination of the more volatile constituents. See LITHOGRAPHY and LITHOGRAPHIC INK.

Li-thog'ra-phy. The process of engraving or drawing on stone, in such a way as to produce a surface from which printed copies can be multiplied in the press.

This great art, now an all-important industry throughout the world, has come into existence and attained its wonderful development within the present century. Until the discovery of lithography by Alois Senefelder, only two methods of printing were known and practiced: that from engraved metallic plates, and that from raised type or wooden blocks. Both of these were essentially mechanical in their nature, mechanical means were used to produce the engraved surfaces, and in printing, the simple adhesiveness of the ink was the one essential condition.

Senefelder discovered and developed to perfection a totally new method, in which the chemical constitution of the materials employed plays a vital part. The history of this invention, which occupied him three or four years, viz. from 1796 to about 1800, is interesting and instructive, but too lengthy for our space. It will be found fully given in his own work upon this subject, which has been translated into English.

The invention was the result of earnest, persistent, and highly intelligent work, tending towards a distinct object which Senefelder kept all the time before his mind, namely, the discovery of a new printing process which would adapt itself to his wants as an author. Much has been said by writers anxious to glorify the mere circumstance at the cost of the mind which grasps and utilizes it, of an accident which helped this great inventor on his way; but it will be found to have had no direct bearing on lithography, which was not invented until three years later, and that the credit of possessing creative genius of the highest order is Senefelder's indisputable right.

Almost the only stone suitable for lithographic work is a compact, sedimentary limestone of a yellowish or bluish-gray color, which comes from the now celebrated Solenhofen quarries in Bavaria. Such stratified slabs of stone as separate naturally into layers of from two to five inches in thickness are fit for lithographic use. They are trimmed on the edges so as to give them a rectangular form, are ground by moving one upon another, with sand and water between, and finally polished with pumice-stone. See LITHOGRAPHIC STONE.

Upon such a surface the artist produces the design to be printed from. This is done by one of four distinct methods: —

1. He draws it with a fluid, watery ink.
2. With a solid crayon.
3. He obtains it by transfer from an inky design produced on paper by various means.
4. He engraves it on a prepared stone.

1. In the first case, the lithographer uses an *ink* which, though it contains other substances, may be regarded as consisting essentially of a soluble soap (stearate or oleate of soda or potash) colored with lampblack sufficient to render it visible upon the gray surface of the stone. (See LITHOGRAPHIC INK.) The design is drawn with a watery solution of such an ink, using a pen or fine hair-pencil, exactly as it is required to appear when printed, and left to dry upon the clean stone. Such a drawing cannot be printed from until subjected to an *etching* process, the object of which is not to elevate or depress the work, but to act upon it chemically. The application of an exceedingly weak acid (nitric or hydrochloric) over the whole surface does not wash away or blur the image as water would; it decomposes the soap contained in the ink, combining with its alkali, and sets free, in intimate contact with the particles of carbonate of lime, of which the stone consists, the insoluble fatty acids contained in the soap. As far as the design is concerned, it is now fit for printing; that is, it would take printing-ink from the roller, but the other parts of the stone would not remain clean. To enable them to do so, the whole surface is flooded over with a solution of gum-arabic in water, the action of which is to incapacitate the clean places for receiving grease of any kind while wet. After a few minutes the excess of gum is washed away, the stone is dried, and placed in the hands of the printer. In appearance no change has taken place; the acid, although it necessarily dissolves part of the stone, does so to an imperceptible extent.

It should be remarked here, that at the present day the practice of applying the dilute acid and gum at the same time is almost invariably followed. The results, in both cases, are identical, but the older

Digitized by Google

method is described above, as better calculated to segregate the changes which take place.

The operation of printing may now be proceeded with. For this purpose the workman places the stone in the press, and adjusts the pressure. He then carefully washes off, with a sponge and abundance of clean water, any excess of gum, and while still wet he *washes out* the remains of the drawing with turpentine, in which it is soluble, using a piece of rag to rub the surface with. This procedure would smear the whole stone and utterly ruin the work, were it not for the protective action of the gum. When wiped clean, the surface at first glance appears to be perfectly blank; but a closer inspection shows the work as a *white* design, *in* the face of the stone.

The printer now passes the roller, charged with printing-ink, to and fro over the stone, which is still damp. The white image instantly takes the greasy ink, and holds it with a strong affinity. (See LITHOGRAPHIC INK.) The film first held by its adhesion accumulates more from the roller, and so on till the workman thinks the design is sufficiently *rolled up*. During this operation the rest of the stone has been kept damp; it will be found to have taken no ink from the roller. A sheet of printing-paper is next laid down upon it, the tympan is closed, and the stone *pulled through*. When again released, and the sheet lifted, the ink will be found to have divided itself between the stone and the paper. In this way lithographic impressions are *pulled;* the operations of *damping*, *rolling in*, and *printing* following each other in constant succession. Should the stone get dry, its surface will immediately take ink indiscriminately; but will part with it on being damped again, if the rolling be continued, without injury to the work. Only after *washing out* with turpentine does the *true white lithographic picture in* the stone become visible, its affinity for the black printing-ink causing it to remain covered all the time.

Such are the facts, without theory, upon which Senefelder's invention is based, and such the phenomena with which every good lithographer ought to be familiar. They repeat themselves, in modified form, in the other three methods, which it will not be necessary to describe at such length. The probable scientific explanation — though it involves the assumption of chemical reactions which many would dispute, and which are by no means demonstrated — is, that it is not simply a greasing of the particles of limestone which enables them to take ink and resist water while thousands of impressions are printing; but the formation of an actual chemical compound, more or less definite in its constitution. In fact, there are many reasons for believing that at the moment when the mineral acid sets the fatty and resinous acids free, they combine with the lime, displacing the carbonic acid, and forming insoluble lime soaps. In like manner it must also be assumed that the gum enters into a more or less perfect union with the substance of the stone, depositing at least an insoluble coating on the particles, which no amount of washing, or even continuous rubbing, can remove; and through which, though infinitely thin, no fatty matter can penetrate. Whatever the nature of this union may be, it is quite as essential to the successful prosecution of lithographic printing, as that produced by the fatty and resinous constituents of the ink, although the vital importance of the function performed by the gum has been almost universally ignored by the few persons who have written on the subject of lithography. It is also highly probable that the change which the gum effects is facilitated and perfected by the slight solvent action of the weak mineral acid on the stone, in consequence of which its surface is rendered chemically clean.

It will be readily understood that want of space, and the chemical character of the subject, make it inexpedient to do more than simply sketch out the above theory, without advancing arguments in its favor.

2. In the second method which the lithographic artist employs to produce his design, he avails himself of the lithographic *crayon* on a *grained* stone, — a stone the surface of which is evenly roughened by grinding it in a peculiar manner with very sharp and even sand. The crayon is composed of soap, wax, tallow, and sometimes resinous substances with lamp-black, and it is used on stone as an ordinary chalk is on rough paper. In the hands of an experienced and capable artist, this modification of the lithographic art offers many advantages; great freedom in execution with delicacy in the lighter shades, as well as vigor, depth, and transparency in the shadows. To accomplish these results, genuine artistic capacity is of more importance than technical training; lithography differing essentially in this respect from the arts of copperplate and wood engraving. The drawing being finished exactly as it is to appear on paper when printed, the stone is acidulated or etched in the manner above explained as applicable to ink employed in the liquid state, and the result is the formation of the same white lithographic picture, capable of taking printing-ink. The effect of the grain of the stone, in giving character to this method, does not require lengthy explanation. It prevents the continuity of the stroke, the particles of chalk closing in round the asperities, and producing deeper tones in proportion as the artist leans more heavily, but rarely or never bridging them over so as to produce perfect blackness, with opacity as a consequence.

A modification of crayon-drawing is the production of *rubbed tints* on stone, chiefly for chromo-lithographic work. The material used as crayon for this purpose is not cast into cylindrical sticks, but applied in larger masses. It is rubbed upon the grained surface pretty freely, and then rubbed off or distributed in accordance with the lights and shades of the design, a small piece of woolen cloth or a *stump* being used for this purpose; afterwards the stone is strongly etched. For soft, undulating surfaces rubbed tints are unsurpassed, and their use does not hinder that of crayon for portions of the work requiring more force and detail than can be readily given by *rubbing*. See LITHOGRAPHIC CRAYON.

3. The third lithographic method is by *transfer*. Of this there are several varieties, but they all resemble each other in the fact that the work is not drawn or engraved upon the stone direct, but is placed there in a completed condition from some source furnishing it, and that paper is invariably used at the medium, by the intervention of which it is carried over.

Autographic transferring, in this country, is almost solely confined to the reproduction of manuscript matter for business purposes. The writing is often done on ordinary, well-sized writing-paper; but better on paper prepared with a thin coating of gelatine, flour-paste, or starch, which may be colored by gamboge. Such a sheet, after being written on, is damped (sometimes with an exceedingly weak acid) and then laid face downward on a clean stone in the press, and *pulled through*. If the paper was well prepared, it will adhere to the stone. It is then damped on the back, and pressure again applied. When, at last, the sheet is carefully lifted, the ink will be left behind in contact with the stone. It is

Digitized by Google

then etched with acidulated gum-water in the usual way, and then printed.

All transferring is done in this manner, save that the ink differs according to the nature of the work.

Autographic transfers, of a very superior character, are quite common in Great Britain. Much of the map-work, ornamental designs, and lettering is done on transfer-paper by persons who make this branch of the art a specialty.

Transferring from stone to stone constitutes at the present day one of the most important and difficult of the processes practiced by the lithographer, and every large establishment has two or three, or more, men who do nothing else.

When a design has been engraved or drawn upon stone — often at considerable expense — it is almost the rule in this country not to print from it direct. It is found safer, quicker, and more economical to preserve the original stone carefully, making as many transfers for the press as the size of the work and that of the edition will warrant. In this way small work, such as labels, show-cards, etc., can be multiplied upon a stone, and the expense of printing proportionately reduced, with a facility which often gives lithography the advantage over typography, even in cost. Very valuable original stones also are saved from the wear and tear of the press, and from accidents; and the artist's work, in place of furnishing but two or three thousand impressions, may yield indirectly many times that number. It is true a transfer is not always equal to the original in quality, but the difference is very slight, and such work is for many purposes quite satisfactory.

Impressions for transfer from stone to stone are pulled or printed very carefully on India proof-paper with a starched surface; but an ink differing from printing-ink is used, the constitution of which makes it very effective when transferred to the clean stone. See LITHOGRAPHIC INK.

Transfers from engraved stones and plates are pulled in the same way as ordinary impressions from such are printed (an operation to be presently described), but with stiff transfer-ink.

Photo-lithographic transfers will be found described under PHOTO-LITHOGRAPHY.

4. Engraving on stone — the fourth subdivision of the art — is essentially different from the preceding methods of producing a printing-surface. It is very largely practiced, however, especially in the United States, and is of much importance.

For this purpose, after a stone of suitable size is polished, its whole surface is etched or prepared with gum-water and an exceedingly dilute acid, and its face is then colored black with a trace of lampblack, or red with a little powdered red chalk, and let dry. The coloration is simply to enable the engraver to see his work as it progresses. Upon this surface the design is now engraved, or rather scratched; sharp-pointed steel needles and the diamond being almost the only tools used. When the design is finished, oil is poured over the whole, and some time is allowed for its absorption by the stone where the needle has laid it bare. The coloring matter, and any excess of gum upon the surface, is next washed off, and ink is rubbed into the lines with a *tampon* or pad, made of some folds of woolen cloth fastened to the face of a small piece of flat wood. As the treatment with gum protects the rest of the stone, it will remain clean as long as damp. If an impression be now pulled, the sheet will lift the ink out of the lines, which are very shallow, as in copperplate printing. From the foregoing it will be seen that printing from an engraved stone is an interesting and complex operation. The ink is held not only by the peculiar nature of the lithographic picture, which forms the bottom of the lines, but also mechanically by reason of their depression and depth; and the rest of the surface is clean, not because it is wiped off mechanically as in copperplate printing, but because it is damp and does not take ink. Lithographic engraving, however, differs considerably from engraving on copper or steel. As it is done in a friable substance with the needle, the boundaries of the lines never attain the smoothness and clearness which are given by the graver, though the approximation is much closer than would be supposed possible, the dexterous use of the diamond giving wonderful perfection in this respect. The ponderousness of the stones, and the *drawing* character of the method, take also from the freedom and sweep which the experienced copperplate engraver imparts so readily to his work; lastly, the depth of the line cannot be proportioned to its width, as is the case on steel or copper. At the present day very little printing is done from engraved stones, — almost none in this country, — but they are constantly used, nevertheless, in consequence of the great facility with which transfers of the finest and most delicate designs can be made from them, and from them only.

Printing from engraved work is slow, and therefore costly, but after transfer it is done with the roller and without unusual expense. In this way it is possible to supply work (so fine that it can only be produced with the needle and diamond) at a very moderate cost.

A most striking elaboration of this system is to be found in the commercial lithography of the United States, especially bonds, checks, certificates of stocks, etc., which, in redundancy of ornament (excellent as to quality), are not equalled by that of any other country. The vignettes, borders, etc., for such documents are all transferred from separate engraved stones, which are retained on hand in great variety as an important part of the lithographer's stock in trade, and from them any particular design can be compiled or built up and transferred to a smooth stone.

Analogous to lithographic engraving is the process of etching on stone, so as to produce a similar result. This is sometimes used very successfully on ruled shades and tints. For this purpose, the stone is protected by a shellac ground, which is cut through by the steel-point or diamond, generally the latter. A wall of wax is then raised round the edge of the stone, and dilute nitric or hydrochloric acid poured on. When bitten deep enough, the lines are filled with thick lithographic writing-ink, and let dry. The ground is then removed and the surface etched strongly with acid and gum. This modification is generally used in combination with engraving to produce certain effects.

In addition to the foregoing four great subdivisions of the lithographic art, various expedients are used to produce certain results which hardly deserve mention here. One exception, perhaps, is to be found in a method, very commonly followed, of obtaining graduated tints for color-printing. For this purpose, a solution of asphalt and crayon in turpentine is applied to a grain stone, let dry, and then scraped more or less with a scraper or knife, according to the tint required. The stone is then etched, washed out, and printed. This method is now superseded in many establishments by the rubbed tint already described.

Chromo-lithography is doubtless the highest de-

Digitized by Google

velopment of the lithographic art. For it all the foregoing methods are put in requisition, but it does not itself constitute an essentially distinct method in a technical sense. In the imitation and reproduction of oil and water-color paintings, much knowledge and experience not possessed by the ordinary lithographer are required; still the novel and difficult part of the art of making first-class chromos lies in the appreciation and selection of colors, their judicious superimposing and blending, and above all things in a cultivated estimation of the true value of a picture and of pictorial effects generally. See CHROMO-LITHOGRAPH.

Senefelder died in 1834. Every phase of the lithographic art described in the preceding sketch was indicated, originated, or practiced by him. Even chromo-lithography was suggested and anticipated by him. The development and perfection of the present day, in every branch of his great invention, would gratify and astonish him infinitely; he would gaze in amazement at the lithographic power-press, printing thousands of sheets daily; and his philanthropic mind would be lost in admiration at the sight of a chromo, which he would confound with the original painting, and which his art has placed within the reach of every one. All this he would readily comprehend; *photo*-lithography alone would be to him a mystery and a revelation. — *Contributed to this work by Mr. J. W. Osborne.*

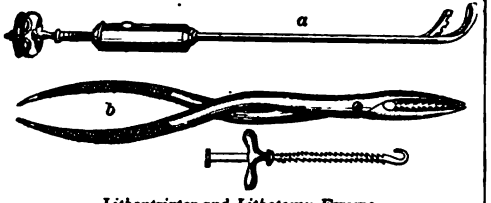
Lith'o-labe. (*Surgical.*) An instrument for grasping a stone in the bladder, and holding it while it is being acted upon by a lithotritic instrument. The *lithoprione* is a form of litholabe.

Lith'o-lyte. (*Surgical.*) A form of catheter for conveying solvents of calculi into the bladder.

Lith'on-trip'tor. An instrument for crushing the stone in the bladder into minute fragments, that they may pass out with the urine.

The instrument *a* is made of two halves, one sliding within the other, and is of the size and shape of an

Fig. 2978.



Lithontriptor and Lithotomy-Forceps.

ordinary catheter when closed. It is introduced into the bladder by the urethra; then, by means of a screw or rack and pinion worked on the outer extremity, the movable part is made to slide back within the bladder, now forming two jaws by which the stone is seized; by turning the screw or handle, the blade is propelled onward again by short jerks, thus breaking the stone into fragments so minute that they may pass the urethra.

This is followed by the use of the lithotriptic instrument, the *evacuating catheter* or *double-current catheter*, which is a catheter of moderate size, having a wall along its center, dividing it into two canals. By means of the upper one the bladder is filled with tepid water, which finds its exit through the lower one, carrying with it all particles of stone remaining after the operation of lithotrity.

The temple of Serapis in Alexandria was used as a hospital in the time of the Ptolemies, and here were performed operations in lithotomy, crushing the stone, reducing dislocations, etc.

Ammenius of Alexandria, the first century B. C., proposed and performed the operation of lithotrity, or breaking a calculus in the bladder, when too large for extraction by lithotomy. The Romans seem to have been much subject to the stone in the bladder.

The lithotritor of Celsus (first century A. D.) was a hook inserted behind the stone while it was cleft by the end of a blunt instrument, struck by a hammer. This instrument was similar to some of the modern.

Lith'o-pho-tog'ra-phy. A process by which a photographic picture is developed on stone, so as to admit of impressions being taken therefrom. See PHOTO-LITHOGRAPHY.

Li-thor'i-neur. An instrument invented by Meirieu and Tanchou for filing down a calculus in the bladder.

Lith'o-tint. A process of drawing upon stone, in which the ink is applied to the stone by a camel's-hair pencil.

Lith'o-tome. (*Surgical.*) A bistoury or scalpel for making the incision in lithotomy. This knife is of various sizes and shapes, blunt, probe, or sharp pointed. It is inserted through the groove of the lithotomy-*staff*, through a small opening previously made in the urethra, and carried along into the bladder, making an opening just large enough to allow the extraction of the stone by means of the forceps. The *gorget*, *bisector*, and *bistouri caché* are varieties of *lithotomes*. Hippocrates, d. 357 B. C., treats of the operation of lithotomy, which seems in his time to have been practiced as a specialty by certain chirurgeons. Five methods of operating are enumerated by Dunglison, in some cases requiring special instruments. As it is the neck or body of the bladder that is cut, the instrument might more properly be called a *cystotome*.

Li-thot'o-mé-cache. (*Surgical.*) An instrument used in lithotomy. It is introduced with blades concealed in a sheath, from which they are protruded, by pressing upon a lever, on reaching the place of operation. The incision is made by withdrawing the instrument. It is made single or double bladed. Called also a *bistouri-caché*.

This instrument is specifically recommended by Sabatier, 1797, in an article read before the National Institute of France, October 6, 1797.

Li-thot'o-my-bi-sect'or. (*Surgical.*) An instrument for making the bilateral incisions in lithotomy.

Li-thot'o-my-for'ceps. An instrument (*b*, Fig. 2978) for extracting stone from the bladder through the opening previously made by lithotomy. Its blades are concave, with rasp teeth cut in to take a firm hold on the stone, the outer surface well rounded to admit of easy introduction, with crossed shanks so that the blades may be fully opened within the bladder without expanding the wound.

Li-thot'o-my-gor'get. (*Surgical.*) A lithotome with one or two concealed blades which are exposed by pressure when required.

Li-thot'o-my-scoop. (*Surgical.*) A small, spoon-like instrument for removing calculi or fragments of stone from the bladder, after the operation of lithotomy or lithontripsy.

Li-thot'o-my-search'er. (*Surgical.*) See LITHOTOMY-SOUND.

Li-thot'o-my-sound. (*Surgical.*) A steel, catheter-shaped instrument introduced into the bladder by the urethra. It indicates the presence of stone by a peculiar click when it comes in contact with it.

Li-thot'o-my-staff. (*Surgical.*) An instrument curved like a catheter and with a deep groove

Digitized by Google

on the convex side of its curved portion, introduced into the bladder by the urethra, for the purpose of guiding the cutting-instrument in lithotomy.

Lith'o-trip'tor. See LITHONTRIPTOR.

Lith'o-tri'ter. See LITHONTRIPTOR.

Lith'o-type. 1. A stereotype in which the surface is composed of gum-shellac, fine sand, and a little tar and linseed-oil.

2. A name signifying printing from stone. The lithographic design on the stone is deeply etched, giving a sufficient relief for the type-press.

Lit'mus. A coloring matter produced from the lichen *Rocella tinctoria.*

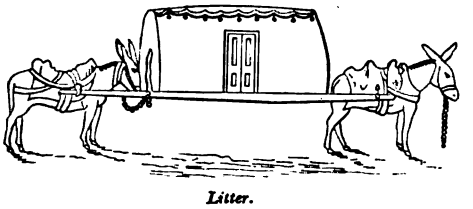
Li-tram'e-ter. An instrument for ascertaining the specific gravity of liquids, invented by Dr. Hare of Philadelphia.

It is founded upon the principle that, when columns of different liquids are elevated by the same pressure, their hights must be inversely as their gravities. It consists of two tubes, their lower ends open and submerged in two liquids whose specific gravity is to be compared, say one vessel of water and the other of an oil or spirit. The tubes connect above with a horizontal pipe, from which the air is exhausted by an air-pump. Atmospheric pressure causes the liquids to rise in the tubes to a hight according to their gravity.

Lit'ter. A *stretcher* with a bed, and in many cases a canopy; used, not as the stretcher ordinarily is, in emergency and haste, but provided for the use of the civil sick, during necessary transportation home or hospital-ward.

Another form of litter is adapted to be carried by two animals. This approaches or reaches the palan-

Fig. 2979.



Litter.

quin, and there is probably no absolute dividing-line between the two.

The litter (*lectica*) on which the body of Augustus was carried to the grave was made of ivory and gold, and covered with costly purple drapery worked with gold.

Stretchers were used in the Roman army to carry wounded officers.

The Asiatic litter was introduced into Greece, having four posts, canopy, and curtains. They were carried by four bearers, and used in traveling. When standing, it rested on four feet. The *lectica* of the Empire was closed with panels of *lapis specularis*, — talc. The poles were removable. It was a palanquin, carried on the shoulders of the bearers.

Companies were formed, and lecticæ were placed in public places for hire.

The lectica was adapted for a person lying down; the *sella*, or sedan-chair, for the sitting posture.

Lit'tress. A smooth kind of cartridge-paper, used in the manufacture of cards.

Live-ax'le. One communicating power; in contradistinction to a *dead* or *blind axle.*

Live-box. A cell in which living microscopic objects are confined for observation. It has a tubular piece with a glass top, upon which slips an upper ring having also a glass top. The object is confined between the glasses.

Live-gang. (*Saw.*) A gang-saw mill, so arranged as to cut through and through the logs without previous slabbing. The bark and wany edge are afterward removed from each board by a *double edger.* The lumber goes to market of the full width.

Live-head. (*Lathe.*) The *head-stock* of a lathe, which contains the *live-spindle;* in contradistinction to the *dead-head* or *tail-stock,* which contains the *dead-spindle.*

Live-mat'ter. (*Printing.*) Type in page or column ready for printing.

Liv'er of An'ti-mo-ny. A sulphuret of antimony and potassa.

Liv'er of Sul'phur. Fused sulphuret of potassa.

Live-spin'dle. (*Lathe.*) The rotating effective spindle in the *head-stock* of a lathe; in contradistinction to the *dead-spindle* in the *dead-head* or *tail-stock.*

Live-steam. (*Steam-engine.*) 1. Steam from the boiler at its full pressure; in contradistinction to *dead*-steam.

2. Steam from the boiler; in contradistinction to *exhaust-steam.*

Live-trap. A device for imprisoning living microscopic objects. It consists of three parallel glass slips; the middle one has a circular perforation forming the cell, while the other one constitutes the sides.

Lix-iv'i-al Salt. One obtained by leaching.

Lix-iv-i-a'tion. The process of separating a soluble from an insoluble material by a washing or filtering action. *Leaching.*

Lixiviation removes a soluble material, which is the valuable portion, as in discharging a certain amount of syrup from a bone-black filter, by passing water therethrough. The *leaching* of ashes is a familiar instance of lixiviation.

Elutriation is the separation of more soluble and comparatively useless portions from one less soluble, by allowing the latter to settle and decanting the supernatant liquor, as in the case of removing the saccharine and coloring matter from starch in the starch manufacture.

Liz'ard. 1. (*Nautical.*) *a.* A piece of rope having one or more legs with thimbles acting as *fair-leaders* or for other purposes.

b. The *top-gallant lizard* is a rope with one end hitched to a hole in the *royal-pole* and the other spliced round a thimble on the hauling part of the mast-rope. It keeps the mast from turning over when its head comes below the topmast crosstrees.

2. A crotch of timber or a forked limb, used as a sled to support a stone being hauled off a field. A *stone-boat.*

Li-ziere'. (*Fortification.*) A *berme.* A small coping or space between the foot of the parapet and the scarp.

Load. The amount of work done by an engine working up to its capacity. Not to be confounded with *duty.*

Load'er. A machine attached to a wagon, as a *hay-loader* or *stone-loader.* In the former case, it is an endless traveling apron on a truck, trailing behind the wagon and carrying up the hay collected by a rake. See HAY-LOADER.

Load'ing-fun'nel. One for charging mortars with loose powder.

Load'ing-ham'mer. One for loading rifles.

Load'stone. A natural magnet. An ore of iron; the protoxide and peroxide of iron in combination. See MAGNET.

Load Wa'ter-line. (*Nautical.*) The line of

Digitized by Google

flotation of a ship when she has her full cargo on board.

Loaf. 1. The conical mass of molded sugar.

2. A shaped mass of light bread in the dough state, or baked.

Loam. (*Founding.*) A mixture which essentially consists of sand and clay, the former largely predominating, with a certain quantity of horse-dung added, or some equivalent for the same, such as chopped straw, sawdust, cow-hair, etc. Beds of loam are sometimes found of nearly suitable composition, but it is more commonly made up by blending different sorts of sand, clay, etc., in a mill resembling a pug-mill. In molding, it is always used quite wet, like plaster, but is dried perfectly before pouring. Its characteristics must be plasticity while wet, strength and solidity when dry, perviousness to the *air* from the mold, and the power to resist the high temperature of the metal. It is employed for large work in both brass and iron, obviating the use of a pattern, as already explained. See MOLD.

Loam-beat'er. (*Founding.*) The rammer of a molder, used in compacting the loam around the pattern.

Loam-board. (*Founding.*) Cores which are struck up upon a spindle or barrel are supplied with loam from a board placed across the trestles on which the barrel revolves, which is hence called a *loam-board.* This is cut to the shape of the core. It is also used after the latter is dry, as a rest on which to place the tool (a very broad chisel with a short handle at each end) used to turn it down to the exact size and shape, before black-washing.

Loam-cake. A disk of loam which covers in the mold in *loam-work* casting, and which is perforated with holes for the entry of the metal and the escape of the air.

Loam-mold'ing. Making a mold by templets. See MOLDING.

Loam-plate. (*Founding.*) One of the flat cast-iron rings or plates used in loam-molding, upon which the nowel or the cope rests, as the case may be.

Loam-work. A method of making molds for large hollow castings, such as cisterns, tanks, steam-engine cylinders, and kettles of large size, etc.

Instead of making a pattern of the object, the *nowel* and *cope* are built up of bricks and covered with loam, which is shaped by a templet. The parts are afterward brought into the required juxtaposition in a pit, surrounded by packed sand, and then the metal is run in.

Lob'bing. (*Metallurgy.*) Breaking blocks of ore into pieces with the hammer, for assortment as to quality with such ores as copper, and for more effectual treatment in the preparatory roasting or calcining processes. Otherwise called *cobbing.*

Lobe-plate. A strong piece of cast-iron laid upon the keelson, etc., to support the parts of a marine steam-engine. A *sole-plate.* A *foundation-plate.*

Lo'cal. (*Telegraphy.*) The battery of a *local circuit.* The latter is one which includes only the apparatus in an office, and is closed by a relay.

Loch'a-ber-axe. The battle-axe of the Highlanders.

Lock. (Anglo-Saxon, *loc,* an inclosure or fastening.) 1. A device having a bolt moved by a key, and serving to secure a door, lid, or other object.

The ancients, though possessing many valuable arts and great skill, do not seem to have been successful in locks. Those of the Egyptians, Greeks, and Romans were clumsy contrivances. Denon has an engraving of an Egyptian lock of wood, which is similar to the one shown at *A,* Fig. 2980.

The locks used to the present day in Syria are much like those used over 2,000 years ago in Palestine and in Egypt. Thompson mentions that the steward of the Carmelite Convent, on Mt. Carmel, opened his magazine with a key as large as a club; reminding him of the passage, "And the key of the house of David will I lay upon his shoulder." — Isaiah xxii. 22.

The strongholds of the castles of Syria yet have enormous locks and keys. They are placed on the inside of the doors, and have a number of metallic wards which are adjusted by the pins on the key. A hole is cut through the door, and the hand and arm thrust through to insert the key. "My beloved put in his hand by the hole of the door, and my bowels were moved for him." (Canticles v. 4.) That is the way "the beloved" let himself into the chamber.

In the Book of Judges, chapter iii. verses 23 – 25, it is stated that Ehud, going forth, locked the doors, and his servants took a key and opened them. This was 1336 B. C., and is the first mention of a key which could be taken out of the lock.

A, Fig. 2980, shows one of these Oriental locks. The following is the description given in Eton's "Survey of the Turkish Empire," published towards the close of the last century. It will answer as well for the present time: —

"The key goes into the back part of the bolt, and is composed of a square stick with five or six iron or wooden pins, about half an inch long, towards the end of it, placed at irregular distances, and answering to holes in the upper part of the bolt, which is pierced with a square hole to receive the key. The key, being put in as far as it will go, is then lifted up; and the pins, entering the corresponding holes, raise other pins which had dropped into these holes from the part of the lock immediately above, and which have heads to prevent them falling lower than is necessary. The bolt, being thus freed from the upper pins, is drawn back by means of the key; the key is then lowered, and may be drawn out of the bolt. To lock it again, the bolt is only pushed in, and the upper pins fall into the holes in the bolt by their own weight."

Locks of this kind are supposed to have been exchanged by the Phœnician navigators with the people of Cornwall for tin, and locks of this pattern, but home-made, still exist in that queer old prong of Britain.

Occasional notices are found among the Greek and Roman writers of the keys of their times; as when Aratus compares the constellation of Cassiopeia to a Roman key, "having a curved stem" and a handle "shaped like the south stars" of the group. Ariston also refers to their "deeply bent" stems, and Eustathius compares them to sickles; and indeed some were so large that they might fairly be carried over the shoulders, as described by Callimachus in his "Hymn to Ceres," where he represents the priestess of Nicippe carrying her key in that manner.

Homer's allusion to the lock on the wardrobe of Penelope is thus rendered by Pope: —

> "A brazen key she held, the handle turned,
> With steel and polished ivory adorned.
> The bolt, obedient to the silken string,
> Forsakes the staple as she pulls the ring;
> The wards, respondent to the key, turn round,
> The bars fly back, the flying valves resound;
> Loud as a bull makes hill and valley ring,
> So roared the lock when it released the spring."

It is said that locks with sliders and tumblers have for centuries been made in China.

Tradition says that locks were made in England in the reign of Alfred, but it was not till the fourteenth century that the craft was recognized as a

Digitized by Google

distinct one. In the reign of Elizabeth, locks with bells or chimes attached were so constructed as to ring an alarm or play a tune when tampered with. The medieval locks were often highly ornamented and artistic pieces of workmanship, constituting quite an important part of the church-door or cabinet to which they were attached. A number yet survive on the cathedrals and churches of Europe, and on the plate and muniment chests of the old families.

The letter-lock is a Dutch invention, but is ascribed, in the "Memorabilia" of Vanhagen von Ense, written about 1650, to Regnier, Director of the Musée d'Artillerie at Paris. Regnier's locks were much esteemed, and the courier's dispatch-boxes were fastened with them. They are, however, alluded to in Beaumont and Fletcher's "The Noble Gentleman," printed in 1615. See LETTER-LOCK, p. 1292. Carew, in some verses written five years later, has this reference: —

> "As doeth a lock that goes
> With letters; for, till every one be known,
> The lock 's as fast as though you had found none."

The letters of the alphabet were engraved on four parallel revolving rings, which by prearrangement on the part of the owner were made to spell a certain word, or number of words, before the lock could be opened.

A French treatise, *L'Art de Serrurier*, published in 1767, contains many examples of the locks of that and former periods. It appears that, though the art had advanced as far as the invention of the single tumbler, yet the main dependence was placed on the complexity of the wards. Multiple bolts, shot simultaneously by a single key, were much in vogue. One lock, figuring in this work as attached to a large coffer or chest, has as many as twelve of these bolts.

The simplest modern form of lock is the common spring-lock, the interior arrangement of which is shown at *B*. In the cut, the bolt is represented half shot. At *a a* are two notches on the under side of the bolt, connected by a curved part; *b* is the back spring, which becomes compressed by the passage of the curve through a limited aperture in the rim *c c* of the lock. When the bolt is wholly withdrawn, one of the notches *a* rests upon the rim *c c*, and the force with which the notch falls into this position, urged by the spring *b*, gives rise to the snapping or clicking noise. When the bolt is wholly shot, the other notch rests in like manner upon the edge of the aperture in the rim.

Wards, or *wheels*, were among the most important improvements in locks, and when sufficiently complicated were considered, especially when the lock was provided with numerous and strong bolts, as affording nearly perfect security.

Wards, shown at *B* and *C*, are pieces of metal having a circular curvature, and are affixed to the interior of the lock. They may be in cross-section of any shape, affording sufficient strength to resist the usual wear and tear occasioned by the motion of the key, which is very slight. They fit into clefts or grooves in the key, which turns around upon them, and prevent the lock from being opened except by its own proper key, or by a key so constructed as to avoid them altogether.

G is a ward-lock key and its keyhole. The various parts are, —

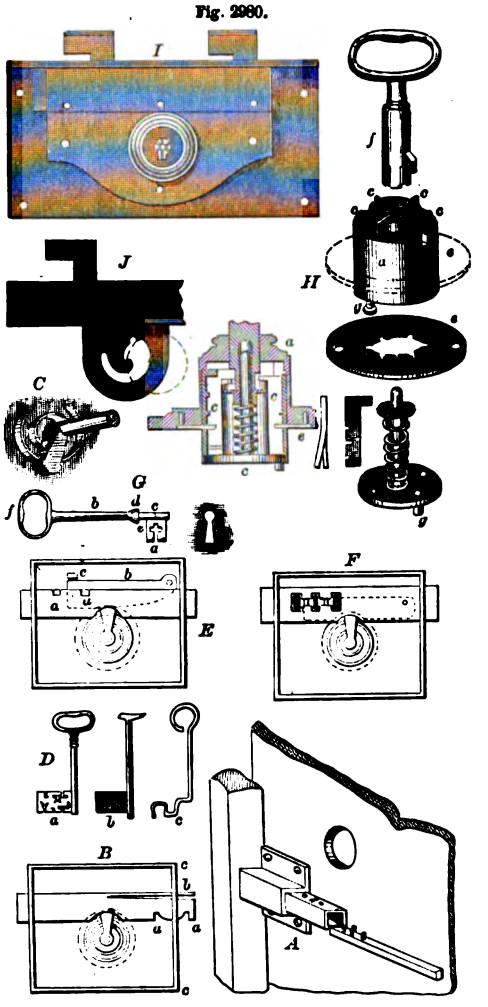
a, the *main*-ward, or *bridge*-ward.
b, *stem*, or *body*.
c, *pin*.
d, *collar*.
e, *bit*, or *web*.
f, *bow*.
g, *eye*.
h, *slot*.

D shows the manner of opening a warded lock by means of a false key. *a* is the true key, the wards of which are somewhat complex. An instrument *b*, covered with wax or soap on one side, is inserted in the keyhole and turned, receiving a perfect impression of the wards. A piece of wire *c* is then bent into such a shape as to avoid contact with these when turned in the lock, withdrawing the bolt with as much facility as the proper key would do.

This is a *skeleton*-key. A *master*-key is similar in principle, being so constructed as to avoid the wards of a set of locks. Such keys are adapted to locks having wards of the same general form.

The period of the invention of tumbler-locks (*E*) is unknown. Some elaborate examples are exhibited

Fig. 2980.



Locks.

in the French treatise before referred to, published in 1767.

The *tumbler* is a lever or latch which falls into a notch of the bolt, and prevents it from being shot until the tumbler has been raised or released by the action of the key. A simple form is shown at *E*. The bolt has two square notches *a a* in its upper edge. Behind the bolt is the tumbler *b*, pivoted at one end, and having a projecting stump *c* at the other, which, in either position, locked or unlocked,

Digitized by Google

falls into one of the notches of the bolt. The tumbler must first be lifted by the key, releasing the stump from the notch in the bolt before the key can act on the latter to turn it either way.

Barron's tumbler-lock was patented in 1778. Its principle consisted in an arrangement "to allow a stump on the tumbler to pass through an opening in the bolt, or a stump on the bolt to pass through an opening in the tumbler."

The former arrangement is shown at *F*. This lock has two tumblers of unequal width, each having a stump or stud which, when the lock is in either a locked or unlocked position, rests in one of the notches represented in the bottom of the gating of the bolt. The web of the key has two unequal steps which, when the key is turned in the lock, elevate the tumblers equally and to a sufficient hight to lift the stumps clear of the lower notches in the bolt and bring them exactly on a level with the gating or slot in the bolt, permitting the latter to slide freely; whereas, if an improper key be used, they will be either lifted too high or too low, so that it cannot pass.

The patents granted for locks, both in England and this country, since Barron's time, have been very numerous. Brahmah's, patented in England, 1784, is shown at *H*. It has a central barrel *a*, having grooves in which are a number of sliders *c c*, whose ends rest against the spring. Each of these is notched at a different part of its length, so that they must be unequally depressed before the plate *e* can enter all the notches simultaneously, and allow the barrel *a* to turn so as to actuate the bolt. This is effected by a stud *g* working in the slot on the bolt shown at *J*. The sliders are provided with false notches to increase the difficulty which a burglar would experience in finding the position of the true ones. The key *f* has longitudinal slots corresponding in length to the distance which each slider must be depressed.

I is an exterior view of the lock, and *J* shows the form of the bolt and the manner in which the rotation of the barrel is made effective in throwing the bolt.

The patent of Mitchell and Lawton, 1815, embraced, among other devices, a revolving curtain for closing the keyhole.

A detector which indicated if any of the tumblers had been overlifted was patented by Ruxton in 1816.

In the same year, Kemp devised a lock whose sliders were operated by a set of small concentric tubes in the barrel of the key.

Paper secured over the keyhole to indicate tampering was patented by Gottleib, 1829.

At the present day, the aid of photography has been called into requisition as a detector.

Two photographs are made from an irregular pattern, one of which is placed over the keyhole, and the other is retained. The American Seal-Lock Company employs sheets of variegated glass, cut into strips, for this purpose. Access to the keyhole can only be obtained by breaking the glass, which of course cannot be replaced. See SEAL-LOCK.

Chubb's lock, 1818, has six or more tumblers turning on a pin common to all. Each of these must be lifted to a different hight before a stud on the bolt can pass through a continuous aperture formed by a slot in each tumbler when all are in their proper position. Should either of the tumblers be overlifted by the introduction of a false key, it is held in that position by a spring, thus indicating that the lock has been tampered with.

In Newell's American lock (exhibited in England in 1851) the bits are interchangeable on the stem of the key, so that an indefinite number of combinations may be formed, each of which so alters the relative position of the tumblers at the moment of locking that they can only be brought into position to allow the bolt to be withdrawn by the same arrangement of the bits. There are three sets of bits, the two nearest the keyhole falling to a common level when the key is withdrawn, while those of the third, which are inaccessible to the "feeling" devices of the burglar, remain at the different hights to which they were lifted by the key through the medium of the other two. See PERMUTATION-LOCK.

It has been proposed to construct locks with clock-work attachments, so that they cannot be opened, even with their proper key, until a regulated interval of time has elapsed. Mr. Rutherford of Jedburg, Scotland, patented a lock of this description in 1831.

A circular stop-plate is placed against the end of the bolt of the lock, and so adjusted that the bolt cannot be withdrawn until a particular notch in the rim of the circular plate is, by means of clock-work, brought opposite the end of the bolt.

Locks having pins or pipe-shafts fitting in the pipe or barrel of a key can only be opened from one side, but those adapted for keys with a solid stem can be opened from either side. In the latter case, only one half the key acts at once.

The variety, both in the form and nomenclature of locks, is very great. Not all of the English trade terms for locks obtain with us. The following is a summary; some of the distinctions are evident, others will be explained:—

A *bolt-lock* is one the bolt of which can only be driven or withdrawn by the action of a key.

A *latch-lock* can be opened by a knob on the inside, but requires the use of a key on the outside.

In-door and *out-door* locks, on the respective sides of a door.

Door-locks are known as *iron-rim*, *brass-case*, or *mortise*, according to the quality or mode of fitting. The *draw-back* has a bolt capable of three positions, *locked*, *latched*, or *open*. The *spring-stock* is a wooden door-lock of inferior quality.

The *dead-lock* or *closet-lock* has a single bolt.

The *two-bolt* has a latch and bolt.

The *three-bolt* has the addition of an interior bolt, not operatable from the outside by any means.

The *knob-lock* and *ring-lock* are so named from the forms of their handles.

The *right-hand* and *left-hand* locks are for door to swing to the right or to the left.

A *dormant-lock* is one having a bolt that will not close of itself.

A *spring-lock* is one whose bolt is protracted by a spring.

A *rim-lock* is named from its shape.

Ward-locks are so called from having *wards* corresponding to clefts in the key, into which they must enter before the key can be turned. They are known as *one-ward*, *two-ward*, etc., according to number; the round wards being sometimes called *wheels*, as *one-wheel*, *two-wheel*. The shape of the ward sometimes gives a name, as L-*ward*, T-*ward*, Z-*ward*. If the ward be cast solid instead of being made of a bent strip, the lock is termed *solid-ward*.

A lock without wards is a *plain-lock*.

Straight-locks have a plate screwed flat against the woodwork; *cut-locks* are inserted into the woodwork, so as to lie flush therewith. *Mortise-locks* are slipped into a mortise cut into the *edge* of the door.

Tumbler-locks have one or more pivoted pieces, called *tumblers*, provided with a lug or dog fitting a notch in the bolt, from which the dog must be released before the bolt can be thrown.

The *letter*, *puzzle*, *permutation*, or *combination* lock has usually a series of notched rings, which must be

Digitized by Google

turned until all the notches are in line in order to enter or withdraw the bolt.

Wheel-locks are those in which one or more wheels form a part of the interior mechanism.

Detector, protector, paranoptic, vibrating-guard, compound-lever, defiance, duplex, detent, holdfast, drill-proof, are among the names given by inventors to various descriptions of patented locks.

The *stock-lock* is an outside wooden lock for stables, gates, etc.

D-locks and P-locks are gate-locks of forms resembling those letters.

Many locks are known by their adaptation to specific uses; as, *cabinet, cupboard, bookcase, desk, portable desk, table, drawer, box, cuddy, chest, carpet-bag, valise, trunk,* etc., locks. See list, p. 1342.

2. (*Hydraulic Engineering.*) *a.* An inclosure in a canal between gates, where boats are raised and lowered. See CANAL.

The parts of a canal-lock are, —

The *head-gate* and *tail-gate,* which, with the *side-walls,* inclose the lock-*chamber.* They are made of *framing* with *leaf-planking* nailed and bolted thereto.

The *clap-sill* or *miter-sill,* with two *branches,* is the framing against which the lower edge of the gate shuts.

The *hollow-quoin* is the recess in the masonry occupied by the *heel-post* of the gate.

The *head-bay* or *head-crown* is the canal above the lock.

The *tail-bay* or *aft-bay,* below the lock-chamber.

The *lift* is the amount of fall overcome by the lock.

The *lift-wall* is the wall at the foot of the head-gate.

A canal-lock is a device by which boats are passed from one level to another. It consists of a basin between the levels, having a pair of gates at each end communicating with the respective level. Fig. 2981 shows a vertical, longitudinal section *a,* a plan *b,* and views of the upper and lower gate *c d.*

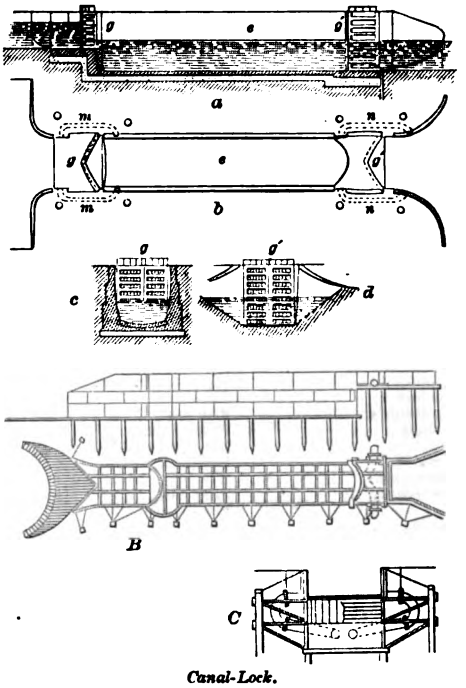
e is the lock-chamber; the floor is called the *invert,* and is lined with masonry. The floor of the upper end is even with the upper level, and the lower floor with the lower level. The gates are shown at *g g'*; they turn upon their hingeing ends; when shut, they close against each other, presenting an angle up hill against the force of the water. When a boat is to ascend, the lower gates are opened, the boat floated into the chamber, and the gates closed. Water is then allowed to pass by underground conduits *m m* to the chamber, until it is even with the water of the upper level; the upper gates are then opened and the boat floated out. In descending, the boat is floated into the full chamber, the upper gates closed; the water in the chamber allowed to pass from the latter by the conduits *n n* to the lower level, until the level of the water on each side of the lower gates is even, when they are opened and the boat floated out.

The Ellesmere and Chester Canal, England, crosses a quicksand in Cheshire, at which place cast-iron locks and lock-gates were made. The locks (*B C*) rise 17 feet, are founded upon piles, and formed of cast-iron plates and girders. The leaves of the gates have cast-iron heads, heels, and ribs, in separate pieces with flanges, which are fastened together with nuts and screws; the whole is covered with wooden planking. The docks and gates are stated to have given good satisfaction.

The complete canal-lock was invented by Dionisio and Pietro Domènico in 1481, consisting, as it did, of a lock-chamber inclosed by a double pair of gates. This invention soon spread throughout Europe, and Leonardo da Vinci erected six of them at the junction of the two canals of Milan, 1497. The fall was 17 Milan brasso. (*Milan brasso = 1.725 English feet.*

In 1188, Alberto Pitentino converted the Mincio into a canal and restored it to its ancient course, from whence it had been diverted by the Romans in the time of Quintus Curtius Hostilius. Cresy dates the introduction of locks from the period of the building of this canal. It was a curious contrivance called a conch, with a balance-lever and hanging gate, which somehow opened to allow the boats to pass. This was used at Governolo, to dam up the

Fig. 2981.



Canal-Lock.

waters of the Mincio on the side of Mantua. It was probably a kind of sluice. See Cresy's "Ency. Civil Engineering," pp. 185–188.

The first canal-lock in England was constructed by John Trew of Glamorganshire for the Exeter Canal. The lock-chambers were 300 feet in length, 80 in breadth at top, 50 at the bottom. The gates were in pairs, at each end, 25 feet high, and each leaf 20 feet wide, furnished with iron and brass work that they might be moved with facility. Sluices were made to admit and remove the water in locking. The object was to ascend to a level in the river Ex, above a weir constructed across the river.

This account disproves the statement that locks were introduced into England by Vermuyden, a Dutch engineer, in the time of Charles I.

A substitute for the lock is found in the *canal-lift,* which is used in some cases, but not with boats of large capacity. See LIFT, CANAL.

b. An embankment or structure confining the waters of a canal or race. A *weir* or *guard-lock.*

3. (*Printing.*) To wedge up a form in a chase by means of *sticks* and *quoins.*

4. A cotter or key; as the one which fastens the

Digitized by Google

cap-square over the trunnion of a mounted cannon. A *forelock*.

5. (*Fire-arms.*) The firing apparatus of a gun, usually consisting of a trigger, sear, hammer, and mainspring. See GUN-LOCK.

6. A fastening for the ends of a hoop which incloses a bale. See BALE-TIE.

7. (*Vehicle.*) *a.* A device to keep a wheel from turning in descending a hill. See WAGON-LOCK; CARRIAGE-LOCK; CAR-BRAKE, etc.

b. The swerving to the right or left of the fore carriage of a vehicle, deviating from the line of direction of the hind wheels and the trend of the carriage proper. It is called the *haw* or the *gee* lock respectively, according as it is to the left or the right of the driver.

8. (*Plastering.*) The projection of the plaster or cement behind the lath, which keeps it from falling or scaling off.

Lock-bay. (*Hydraulic Engineering.*) The pond or space of water between the gates of a canal-lock.

Lock-chain. (*Vehicle.*) A chain employed to lock the wheels by attaching a part of the rim to some non-rotating part of the vehicle. Or a chain by which is secured to the vehicle a *skid-plate*, on which the wheel rides in descending a hill. A *skid-chain*.

Lock-cham'ber. (*Hydraulic Engineering.*) That part of a canal-lock, between the gates, in which a boat rises or sinks to the level above or below. See CANAL-LOCK.

Lock-cramp. An implement used to restrain the spring in putting the parts of a gun-lock together.

Lock'er. (*Nautical.*) A compartment in a ship for stowing away things.

The chain-lockers are centered around the foot of the main-mast.

Shot-lockers are recesses and shelves for shot.

Lockers in the cabin are for various articles, answering to closets, and may be fastened by a lock.

Lock'et. 1. (*Arms.*) That part of a leathern sword-scabbard where the lock is fastened.

2. (*Jewelry.*) *a.* The fastening of a necklace, etc.

b. A gold case with a snapping cover, and adapted to contain hair or a miniature.

Lock-file. A slitting file, knife-shaped, for cutting out the wards in the bit of the key. See FILE.

Lock-fil'ers' Cramp. A pair of leaden or brazen cheeks for a vise.

Lock-gate. (*Hydraulic Engineering.*) A pair of closed doors at one end of a canal-lock, to confine the water in the chamber. The gates at the end of the lock-chamber are respectively the *head-gates* and *tail-gates*. See CANAL-LOCK, p. 440.

The lock-gate consists of two *leaves*, each having a top and bottom cross-piece, diagonal brace, *quoin-post*, also known as a *heel-post*; and *miter-post*, also known as a *meeting-post*. One pair of gates constitute the *head-gate*; the lower pair form the *tail-gate*; the two, with the *side-walls*, inclose the *lock-chamber*.

Lock-hatch. (*Hydraulic Engineering.*) The sluice-board or sliding-gate in a sluiceway.

Lock-hole. The recess in a musket-stock to receive the lock.

Lock'ing-for'ceps. A light forceps whose arms are automatically locked when closed; used for various purposes, such as holding a sponge tent in uterine operations, for carrying lint, etc.

Fig. 2962.

Locking-Forceps.

Lock'ing-plate. 1. (*Horology.*) Or *count-wheel.* A notched circular plate on the great wheel, whose notches receive the end of a lever attached to the *lifting* piece, and by which the number of strokes is governed.

2. (*Vehicle.*) A plate on a vehicle to take the wear of the fore-wheel when the vehicle is turning short. A *rub-plate*.

Lock-nail. One of the pins by which the parts of a gun-lock are secured to the *lock-plate*. In the old form of lock, they are the *tumbler-pin*, *main-spring-screw*, *sear-pin*, *bridle-screw pin*, *hammer-nail*, *hammer-spring screw*.

Lock-nut. A supplementary nut screwed down upon a primary one, to prevent its shaking loose. A *jam-nut*, *check-nut*, or *pinching-nut*.

A *nut-lock* is a means for preventing a nut from turning. See NUT-LOCK.

Lock-pad'dle. (*Hydraulic Engineering.*) A sluice for filling an empty lock-chamber.

Lock-piece. In guns of the old construction, a lug cast just alongside of the vent for the attachment of the lock.

Lock-plate. That plate on which the parts of a gun-lock are fastened, and which is screwed to the stock.

Lock-pul'ley. (*Machinery.*) Two pulleys formed to rotate together or separately, at will. One of them slips on a *spline*, and has a pin which locks into a hole in the face of the other pulley. See PULLEY.

Lock-rail. (*Carpentry.*) Of a door-frame, the

Digitized by Google

transverse piece which separates the main doorway from the open space above it, which is usually occupied by a glazed sash. A *transom*.

Lock'ram. (*Fabric.*) (Fr. *Locronan*, a town of Bretagne.) A hempen cloth.

Lock'rand. (*Masonry.*) A course of bond-stones.

Lock-saw. A *compass-saw* used in cutting seats for locks in doors. It has a fine, taper, flexible blade. See COMPASS-SAW.

Lock-screw. The screw which fastens the gun-lock to the stock.

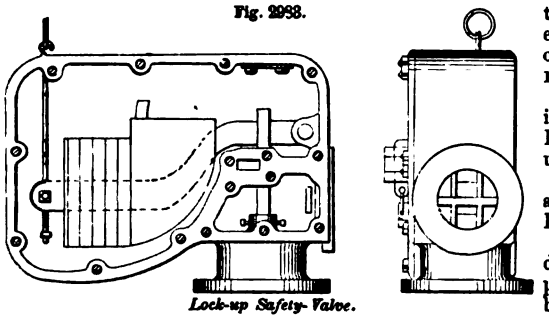
Lock-sill. (*Hydraulic Engineering.*) A piece of timber at the threshold of a canal-lock, with a chamfered edge, against which the gates shut.

Lock-stitch. A sewing-machine stitch in which the lower thread is made to pass over the upper one, simply interlocking therewith. See STITCH.

Lock-tool. A cramp used in putting the parts of a gun-lock together.

Lock-up Safe'ty-valve. A safety-valve which is so inclosed that weight cannot be surreptitiously added to the lever; as in the example, in which the lever and weights are inclosed in a lock-up chamber which the steam does not enter, so that they are secure from access by any not possessed of the key, and can be inspected at any time. A rod passing through the

Fig. 2983.



Lock-up Safety-Valve.

chamber-top enables the engineer to blow off, but affords no facility for holding down the valve.

The lock-up valve was a feature in the specification of a locomotive, for which a prize was offered in 1829, and won by Stephenson's "Rocket."

Lock-wag'on. A device to impede or arrest the motion of one or more wheels of a vehicle when descending a hill, or when it is desired to prevent its being moved. See WAGON-LOCK.

Lock-weir. A weir having a lock-chamber and gates.

Lo'co-mo'tive. A self-moving, traveling steam-engine.

Watt's patents of 1769 and 1784 included the uses of steam-engines for running carriages on land, but he never made any such.

A locomotive was made by Cugnot, a Frenchman, in 1769. It is still preserved in the museum of the Conservatoire des Arts et Métiers at Paris, and is described as having a copper boiler, much like a common kettle, and a pair of 13-inch single-acting cylinders, which operated a single driving-wheel roughened on its periphery. Hornblower's steam-carriage had the same date, 1769.

Symington showed a model of a steam-carriage in Edinburgh in 1770. It was a long-coupled, four-wheeled carriage, the boiler and engine behind, a coach-body on the usual springs, and in front the guard, who governed the fore-wheels by a lever. To the piston-rod was attached a rack gearing into a pinion on the driving-wheel axle. The writer cannot state whether the said pinion was a ratchet, and allowed the rack to *slip* back on its return stroke, or whether it was thrown out of gear in returning while the cylinder on the other side became effective. Its mode of coupling the power to the running-gear resembled, in some respects, his steamboat.

In 1784, William Murdoch of Redruth, Cornwall, England, while in charge of the Boulton and Watt pumping-engine, made a locomotive wherein a lamp supplied the heat. Determining to give it a trial on a road, he lit the lamp beneath the boiler, and as soon as the working parts were thrown into gear, the thing started and got away from him, he following it along the lane at full speed. The night was dark, and the locomotive met and scared the clergyman of the parish, who raised a cry of distress, thinking he had met the Evil One. This locomotive was exhibited before the Institution of Mechanical Engineers in 1850, 66 years after its construction.

Oliver Evans of Philadelphia obtained a patent in Maryland in 1787 for the exclusive right to make steam-wagons for roads and railways. The details of the invention are not known to the writer. His descendants in the third generation are yet inventing. He is entitled to the credit of first making the double-acting high-pressure steam-engine a success. In 1801, he built a floating dredging-machine, to which he fitted wheels connected with the engine, and conveyed it 1½ miles to the place of launching. See HIGH-PRESSURE STEAM-ENGINE.

It is stated that about 1803, a Mr. Fredericks made a locomotive for a silver-mine in Hanover. The principles of construction are unknown.

In 1806, a locomotive to be driven by hot air was constructed by Niepce at Chalons, France.

Trevethick's locomotive had a single cylinder, laid horizontally below the bottom or front part of the boiler, its reciprocating piston-rod being connected by another rod with a crank, at the midlength of an axle which carried a fly-wheel and a pair of cog-wheels, which geared into other spur-wheels on the axle of the driving-wheels. The engine was run upon a railway at Merthyr-Tydvil, in 1802, and drew ten tons in addition to its own load at the rate of five miles per hour. Vivian was associated with Trevethick in the patent. It was high-pressure, non-condensing, and exhausted into the chimney. It may be considered the first locomotive to run on rails or trams.

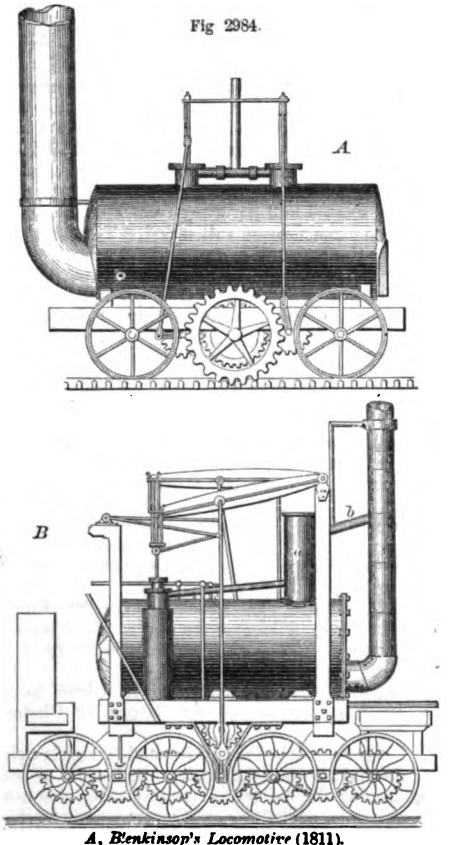
Blenkinsop's locomotive, in 1811, gave still better satisfaction to its owners, and it was usefully employed at the Middleton Colliery in hauling coals on a tramway, the engine having spur-wheels working into a rack on one side of the track. The engine (*A*, Fig. 2984) was otherwise supported on four wheels. The fire was built in a large tube passing through the boiler, and the tube was bent up at the end to form a chimney. Two vertical cylinders were placed above the boiler, and the pistons were connected by cross-heads and connecting-rods to cranks on the axles of spur-pinions, which geared into the main spur-wheel, which formed the driver. It was long used on a colliery railway between Leeds and Middletown, 3½ miles distant, and perhaps was the first successful locomotive in regular use. It drew trains of 30 tons weight 3¾ miles per hour.

In 1812, Blackett made a series of experiments which proved that the expedient of a pinion and rack-rail was unnecessary; and Chapman patented a

Digitized by Google

locomotive with eight wheels driven by gearing, for the purpose of increasing the tractive adhesion. In the same year, Brunton invented a means of driving

Fig 2984.



A, Blenkinsop's Locomotive (1811).
B, Hedley's Locomotive (1813).

a locomotive by two propellers consisting of jointed rods intended to imitate the action of the hind legs of a horse. Analogous contrivances were adopted by Gordon and Gurney.

In the spring of 1813, William Hedley built a locomotive with four smooth drive-wheels, to run on a smooth rail. The machine failed to accomplish much, on account of its small boiler. Hedley thereupon the same year built another engine (shown at *B*, Fig. 2984), having a return-flue boiler, and mounted on eight driving-wheels, which were coupled together by intermediate gear-wheels on the axles, and all propelled by a gear in the center, driven by a pitman from the walking-beam. See "Who Invented the Locomotive-Engine?" London, 1858, written by O. D. Hedley, the son of the inventor.

Hedley's locomotive was objected to by residents of Newcastle, on account of the smoke. He therefore passed the smoke into a large receiver (*a*), and turned the exhaust-steam upon it. From the receiver the steam and smoke were conveyed by a pipe (*b*) to the chimney, which device soon developed into the steam-blast.

"Puffing Billy" was at work more or less until 1862, when it was laid up as a memorial in the British Patent Office Museum. Hedley died in 1842.

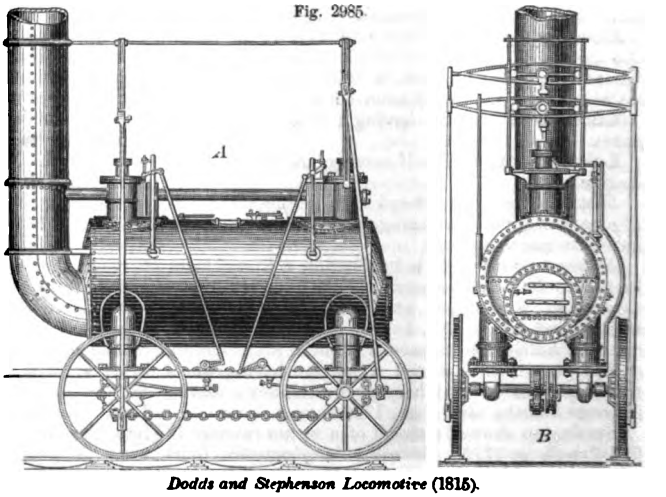
In 1815, Dodds and Stephenson patented an engine (shown by side and end views, Fig. 2985), in which the power might be applied either through wrists, at angles of 90° to each other on the driving-wheel, or an endless chain working in gearing on the axles. A patent was taken out in the succeeding year by Losh and Stephenson, embracing, among other features, a series of cylinders communicating with the water in the boiler, and having pistons with rods at their lower ends, which were caused to press upon axles having vertically movable bearings, so as to keep the wheels down when running on an uneven track. Their first engine is stated to have been made for the Killingworth Railway, and their engines were employed on iron tracks by the Stockton and Darlington Railway in 1825, and, later, at the Newcastle collieries. The locomotive in the Stockton and Darlington Railway had two vertical cylinders, and the driving-shaft had cranks at an angle of 90°. The axles of the wheels were coupled by an endless chain passing around both axles.

In 1829, the Liverpool and Manchester Railway, then the most extensive and finished work of the kind ever undertaken, was completed, and the directors offered a reward of £500 for the best locomotive, which should fulfill certain imposed conditions. Among these were, that it was to consume its own smoke, draw three times its own weight at a rate of not less than 10 miles an hour, and the boiler-pressure was not to exceed 50 pounds per square inch. The weight was not to exceed six tons, nor the cost £550.

Three engines competed for the prize: the "Rocket," constructed by George Stephenson; the "Sans-pareil, by Timothy Hackworth; the "Novelty," by Messrs. Braithewaite and Ericsson.

The "Rocket" weighed 4 tons 5 cwt., and its tender, with water and coke, 3 tons 4 cwt. It had two loaded carriages attached, weighing a little over 9 tons 10 cwt. The greatest velocity attained was 24½ miles per hour, and the average consumption of coke per hour 217 pounds. See *A*, Fig. 2986.

Fig. 2985.



Dodds and Stephenson Locomotive (1815).

Digitized by Google

The "Sansparíel" attained a speed of 22½ miles per hour, but with an expenditure of fuel per hour of 692 pounds.

The "Novelty" carried its own water and fuel. In consequence of successive accidents to the working arrangements, this engine was withdrawn from competition. A fourth engine, the "Perseverance," by Burstall, not being adapted to the track, was withdrawn.

The opening of the Liverpool and Manchester Railroad, September 15, 1829, was an era in civilization, and perhaps the first victim to the iron horse was slain on that day, — Mr. Huskisson, Home Secretary in the British Cabinet. Eight locomotives were used on that day, and while the engines were watering at the Parkside station some of the guests descended to the road. While Mr. Huskisson was talking to the Duke of Wellington, the famous "Rocket" came by, knocked down Mr. Huskisson, and the wheels passed over his left leg. He was placed on board the "Northumbrian," driven by George Stephenson, who conveyed him 15 miles in 25 minutes, at the rate of 36 miles an hour, the most marvelous achievement yet. Mr. Huskisson died the same night at Eccles.

The "Rocket" engine was superseded in 1837, being condemned for life to the collieries. Here it proved itself capable of a rate of 60 miles an hour; but being again convicted of levity while on duty, it was cashiered and its place filled by heavier machines of 12 tons. After a few years of inglorious retirement, some one, not totally oblivious of how it would look in history, recalled the old soldier from his limbo, and now he enjoys the company of his elder brother, Hedley's "Puffing Billy," in the English Patent Museum.

In Fig. 2986, *A* is an elevation of the "Rocket." The boiler *a* is a cylinder 6 feet long, and has 25 tubes. This feature was due to Mr. Henry Booth, though a tubular boiler had been patented by M. Seguin in France, in 1828. The fire-box *b* has two tubes, communicating with the boiler below and above, and is surrounded by an exterior casing, into which the water from the boiler flows and is maintained at the same level as that in the boiler.

B is a longitudinal vertical section of a modern English locomotive. The boiler is surrounded by two casings, one within the other, united by stays. The tubes *a* are of brass, 124 in number, and the boiler has longitudinal stays connecting the ends. *b* is the smoke-box, into which the blast-pipe *c* discharges. *d* is the steam-dome, into which the steam from the upper part of the boiler enters, its amount being governed by a regulator controlled by a winch. This serves to obviate in great degree the effects of priming. The steam-pipe *e* has two branches, each entering one of the boxes containing the valves by which the flow of steam to the cylinders is controlled.

C is an express-engine designed by Gooch for the Great Western Railway, where an unusual rate of speed is maintained. The boiler has 305 tubes, 2 inches in diameter. The cylinders are 18 inches diameter and 24 inches stroke, the driving-wheels 8 feet in diameter, the heating surface of the fire-box 153 square feet.

D is an express-engine designed by Crampton for the same road. It is adapted for the usual gage.

For details of English locomotives, which differ considerably in construction from those used in the United States, the reader is referred to Colburn's "Locomotive Engineering."

The engines employed on the Irish mail-trains between London and Holyhead weigh 27 tons; the tenders 17 tons, carrying 2 tons of coke and 1,500 gallons of water. The cylinders are of 16 inches diameter and 24-inch stroke. The apparatus for feeding the fuel also provides for the combustion of the smoke. The engine is supplied with water while running, from a trough beneath the rails, from which the water is scooped up by the tank. The cost of a locomotive of this description is nearly £3,000. It is said that one of them has been known to run 130 miles in 144 minutes.

Faulding's locomotive (English) is designed to avoid the inertia of its working parts. It has an

Fig. 2986.

B, English Locomotive (Longitudinal Section).
C, Gooch's Express Engine (English).
D, Crampton's Express Engine (English).

oscillating cylinder on each side, which is, by a partition at its midlength, divided into two cylinders, each of whose pistons, coupled directly to the crank-pins, propels one of the four driving-wheels, and is simultaneously driven outward and inward. The crank-axles are at right angles with each other, so that each wheel is driven alternately. The cylinders are carried on a frame supported by the journals of the driving-wheels, so as not to be affected by the motion of the springs.

The first locomotive run on rails outside of England was the "Stourbridge Lion," made by Stephen-

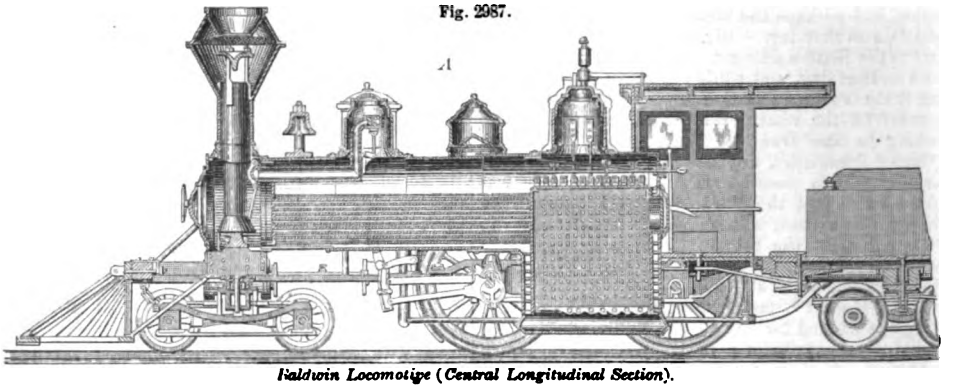
Digitized by Google

son and brought from England for the Delaware and Hudson Canal and Railroad Company by Horatio Allen. This was in August, 1829. It was soon found that English locomotives, adapted for gentle curves, were ill suited for the exigencies of American railroads, where curves of as small a radius as 200 feet were sometimes employed. Mr. Peter Cooper, since so well and widely known, devised an engine which solved the difficulty. This was in 1829.

The second locomotive built in the United States for actual service was for the South Carolina Railroad, and made its first regular trip in March, 1831. See RAILWAY.

The London "Engineer" describes an engine built for the Mt. Cenis Railway as having four drivers and four horizontal wheels, which latter grasp between them a central rail with an amount of pressure regulated by springs, which are controlled by bars bearing upon them, and adjusted by means of a shaft extending across the engine and furnished with right and left handed screws. This shaft carries on its end a worm-wheel, gearing into a worm connected with a hand-wheel on the foot-plate, by which the pressure is regulated. This may be increased to 24 tons, 6 on each wheel.

Fig. 2987.

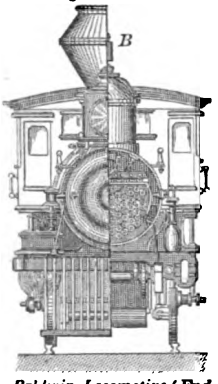


Baldwin Locomotive (Central Longitudinal Section).

Fig. 2987 is a central longitudinal section of an approved form of American locomotive as made at the Baldwin Locomotive Works, Philadelphia.

Fig. 2988 is a front elevation, one half of which shows a transverse section through the boiler. The engine has four drivers, 60½ inches in diameter, and a four-wheeled swing bolster truck, and weighs, with water and fuel, about 65,000 pounds. The flues, 144 in number, are 2 inches in diameter, and 11 feet 5 inches in length. The fire-box, of cast-steel, is 66 inches long, 34½ inches wide, and 63 inches deep. Water-space 3 inches sides and back, 4 inches front. Grates, cast-iron. The cylinders are horizontal. Valve-motion graduated to cut off at any point of the stroke. The tires of cast-steel, and the wheel-centers of cast-iron with hollow spokes and rims; the wrist-pins of cast-steel, the connecting-rods of hammered iron. The truck-wheels are 28 inches in diameter. All the principal parts of the engine are interchangeable.

Fig. 2988.



Baldwin Locomotive (End Elevation and Transverse Section).

Attempts are being made, by adaptation of the furnace and boiler, to run locomotives by means of liquid fuel. Differences also occur in the construction of the heating parts, according to the character of the fuel, — coal, coke, wood, peat, etc.

The ordinary speed attained on English railways is greater than that usual in this country. The Great Western express from London to Exeter travels at the rate of 43 miles an hour including stoppages, or 51 miles an hour while actually running. Midway between some of the stations a speed of 60 miles is attained, and on experimental trips 70 miles an hour has been reached. A speed of 75 miles is equivalent to 35 yards per second, so that if a row of stakes one yard apart were driven at the side of the road, they would at this velocity appear undistinguishable one from another. Were the driving-wheels of the locomotive 7 feet in diameter, they would revolve 5 times in a second, each piston would traverse the cylinder 10 times per second, while there would be 20 discharges of waste-steam per second, causing a continuous sound instead of the "cough" which is heard when the engine is moving slowly.

Very high speeds have been attained, on special occasions, on American roads, probably fully equaling any time ever made in England. For instance, it is stated that a train conveying some officials of the New York Central Railroad made the distance from Rochester to Syracuse, 81 miles, in 61 minutes, said to be the fastest time ever made in America.

The life of a locomotive-engine is stated in a paper read before the British Association at thirty years. Some of the small parts require renewal every six months. The boiler-tubes last five years, and the crank-axles six years; tires, boilers, and fire-boxes, seven to ten years. The side-frames, axles, and other parts, 30 years. During this period, the total cost of repairs is estimated at $ 24,450 in American money, the original cost of the engine being $ 8,490. It therefore requires for repairs in eleven years a sum equal to its original cost. In this time it is estimated that an engine in average use has run 220,000 miles.

See Clark's "Recent Practice on the Locomotive"; Tredgold on "Locomotive-Engines," London, 1851; Heusinger and Clauss's "Locomotive Maschine," Wiesbaden, 1858; Weissenborn's "American Engineering," New York, 1861; "The Student's Guide to the Locomotive," London, 1849.

The following figures, from the *Railway Times*, show the result of locomotive performance on the Cleveland, Columbus, Cincinnati, and Indianapolis Railway, 397 miles, for the month of March, 1872, and may be interesting in this connection: —

feed-pump by which a locomotive-boiler is supplied with water. See INJECTOR.

Lo'co-mo'tive Smoke-pipe. The chimney-stack of a locomotive. See LOCOMOTIVE.

Lo'co-mo'tive Valve-gear. (*Steam-engine.*) The means by which the engineer governs the motions of the valves, opening, closing, or reversing. See LINK-MOTION.

Lode. 1. (*Mining.*) A regular vein affording metal.

When parallel to the axis of elevation of the district, it is termed *right running.*

When at right angles to the said axis, it is termed a *cross course.*

When at an angle of 45°, it is termed a *contra-lode* or *counter.*

A *rake-vein* is a perpendicular mineral lode.

A *live vein* or lode is one which contains metallic ores. It is said to be a *dead* lode when the ores give out.

The *back* is the upper part of a *lode.*

The *walls* or *cheeks* are the sides of the *lode;* as the vein inclines, the *walls* are known as the *upper* or *hanging* wall and the *under* wall.

The *hade* or *hading* is the slope or inclination.

The *bearing* is the course or direction.

The *country* is the rock traversed by the *lode* or *vein.*

Side-lodes, strings, feeders, and *branches* are minor ramifications of a vein or lode.

The *gangue* is the non-metalliferous portion of the vein. (German, *Gang,* vein.)

A *heave* or *fault* is a displacement or dislocation of a vein.

Gossans are surface indications of a vein.

Bunches, nests, concretions, nodules, are detached masses of different characters.

2. (*Hydraulic Engineering.*) A reach of water in a canal, or slack-water navigation.

Lodg'ing-knees. (*Shipbuilding.*) Compass-timbers lying horizontally and securing the junction of the deck-beams with the frames.

Lodg'ment. (*Fortification.*) An intrenchment hastily thrown up in a captured work to maintain the position against recapture.

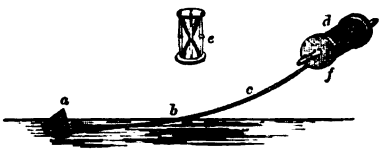
Loft. (*Architecture.*) *a.* An elevated gallery in a church, for an organ or choir.

b. An elevated story in a barn or stable, as a *hay-loft* above the floor on which the animals are stalled.

Log. 1. (*Nautical.*) A device for ascertaining the rate of a ship's motion. In its common form it consists of a triangular piece of wood, called the *log-chip,* curved at the bottom, which is loaded so that it may float upright in the water. It has a radius of about 6 inches, and a thickness of ¼ inch. To its corners is attached a cord, termed the *log-line,* which is wound around a reel, the axis of which projects, allowing it to turn freely when held in the hollow between the thumb and forefinger. The line is long enough to measure the distance sailed by the ship at her greatest speed during a given time, usually 30 seconds, and is divided into *knots,* corresponding to a proportionate part of the nautical mile, that is, 51 feet, though some navigators make it a trifle longer or shorter, as they conceive that the ship overruns or underruns her reckoning.

The string is knotted at such intervals that the spaces bear the same relation to a nautical mile that a half-minute does to an hour. That is, the knots must be the 120th of a nautical mile apart. The English geographical or nautical mile is $\frac{1}{60}$ of a degree of latitude, about 2,025 yards. Each *knot* is therefore $50\frac{7}{10}$ feet. For ordinary land measure, the English statute mile is used, = 5,280 feet. A knot would be 44 feet. See PEDOMETER.

Fig. 2991.



Log.

a, log-chip.
b, stray-line
c, forerunner or *stray-mark.*
d, log-line.
e. sand-glass.
f, reel.

A certain length of line — not marked — intervenes between the chip and the first division on the line. This is termed the *stray-line,* and serves to allow the chip to drift beyond the dead-water in the wake of the ship.

Each knot is made sensible to the feeling as well as to the sight, and is subdivided into ten fathoms, so called. The time is measured by a small sand-glass. In heaving the log, the observer, usually an officer or petty officer, throws the chip over the taffrail, and as the first mark on the line passes over the reel, calls out "turn" to the assistant, who immediately inverts the glass. When the sand has all run out the latter calls out "out," when the observer checks the line, noting the knots and fathoms which have passed out. This operation, in well-regulated vessels, is performed every hour, and the result, as well as the course by compass which the vessel is steering at the time, is entered in the log-book, to serve as a basis for the *dead reckoning.* Sometimes, as in the British navy, a 28″ glass is employed, the length of the line being proportionately reduced.

Estimating a mile at 6,139.75 feet, and using a 30″ glass, —

1 knot = 51.1629 feet, or 51 feet 1.95 inches.
1 fathom = 5.11629 feet, or 5 feet 1.395 inches.

If a 28″ glass is used, and 8 divisions, then —

1 knot = 47 feet 9.024 inches.
1 fathom = 5 feet 11.627 inches.

The line should be about 150 fathoms long, having 10 fathoms between the chip and first knot for stray-line.

Bowditch gives 6,120 feet in a sea-mile, which, if taken as the length, with a 28″ glass, will make the divisions 47.6 feet and 5.95 feet.

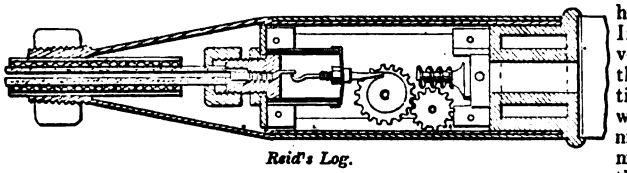
Some logs, the earliest of which, perhaps, was Massey's, are actuated by wings on a rotating rod, which turns as the vessel passes through the water, operating, by means of an endless screw, a series of multiplying wheels, which register the total distance run between the time the log was thrown overboard and that at which it was taken from the water. These are only taken in when the ship's course is changed, or when the speed is below two or three knots per hour. They are somewhat liable to turn up missing, owing probably to their being bitten off by sharks.

Reid's log is of this class, but the spindle which carries the wings is combined with a mechanism for breaking galvanic circuit upon a certain number of rotations of the spindle. The armature operates a registering mechanism.

The "Berthon log" is an adaptation of Pitot's tube. In its elementary form it consists of a small tube passing through the ship's keel nearly amidships, and carried up to any convenient hight, when

Digitized by Google

Fig. 2992.



Reid's Log.

it is curved downward and united to the leg of an inverted siphon containing mercury. When the ship is making headway, the water which enters the tube through an aperture near its lower end rises, forcing up the mercury, which indicates the ship's speed on a suitable register. By turning the tube so that the aperture forms a certain angle with the keel, the ship's draft may be ascertained.

In reference to this subject Humboldt says, —

"It has frequently been asserted that the use of the log for measuring a ship's way dates back only to the end of the sixteenth or beginning of the seventeenth century, the year 1607 being usually assigned as the period when the first mention of it occurs. Navarrete says that it was used on board English ships in 1577, and that in Magellan's time the ship's speed was estimated by the eye. On the contrary, Pigafetta, a companion of Magellan, speaks of the log, *la catena a poppa*, as of a long-known means of measuring distances at sea.

"The Romans, in the time of the Republic, had in their ships an apparatus for measuring the distance passed over, consisting of wheels four feet high, provided with paddles placed outside the ship, after the manner of a modern steamboat, and according to the detailed description of Vitruvius, having a train of gearing consisting of three-toothed wheels, and registering the number of revolutions made by the exterior paddles, and also miles traversed by the ship, by the dropping of small round stones from an aperture in a wheel-case.

"This was constructed on the principle of the odometer (or *hodometer*), which was also employed by the Romans on land, mention being made of a traveling carriage belonging to the Emperor Commodus provided with such an apparatus. Hero of Alexandria, in his manuscript on the *dioptra*, describes an odometer of much more perfect construction, adapted for use both by land and water.

"The earlier nautical works of the Spaniards refer only to the method of arriving at the distance made by estimation; judging the velocity of the ship during the time occupied by the running out of each hour or half-hour glass. This would seem to have involved, on the part of the navigator, if even a rude approximation to accuracy were attained, not only a general knowledge of the usual rate of speed of vessels and an acquaintance with the effects produced by drift and set of the sea, but also with the sailing qualities of the particular vessel in which he happened to be. Medina lays down, as a general rule, that 'the most a ship advances in an hour is four miles, and with feebler breezes three, or even two.' Columbus, in his journal, frequently refers to his disputes with his lieutenant, Pinson, in respect to the distance made by the fleet since leaving Palos, and speaks of making 8 miles per hour, double the speed referred to by Medina. He makes no mention of the log. When it was proposed, in 1495, to determine the Papal line of demarcation between the discoveries of the Spaniards and Portuguese, the distance sailed over was to be determined by the judgment of 20 very experienced mariners, who were to prick off on the chart the distance made by the ship every six hours, according to their estimation. In Pigafetta's journal of Magellan's voyage, he speaks of a 'chain at the poop,' used throughout the entire voyage to measure the way. This would seem to have been an arrangement similar to the log-line, though no mention is made of the sand-glass, the log-chip, or of marks or divisions of the chain."

In connection with this subject, it may be mentioned that Professor Scoresby made careful observations during a passage across the Atlantic and during the prevalence of a protracted storm. He found: —

Extreme altitude of waves above the intervening depressions or hollows .	43 feet.
Mean distance between waves . .	559 "
Extreme distance from crest to crest .	600 "
Interval of time between waves .	16 seconds.
Velocity per hour	32½ miles.

Newton found that the velocity of the waves is as the square roots of their breadths; as taken between the tops of the ridges. Also, that they move through a space equal to their breadth in the same time in which a pendulum oscillates whose length is equal to the distance between the ridges. Waves whose breadth is 39½ inches will move that distance in a second of time. Their motion is progressive, but does not impart a like motion to a floating object, as the water does not move at the rate of the undulations.

2. (*Steam-engine.*) A tabulated summary of the performance of the engines and boilers, and of the consumption of coals, tallow, oil, and other engineers' stores on board a steam-vessel.

3. A stick of timber butted at the ends and ready for sawing.

Log-board. (*Nautical.*) The hinged pair of boards on which the memoranda of time, wind, course, rate, etc., are noted for transcription into the *log-book*.

Log-book. (*Nautical.*) The book which contains a journal of the vessel's progress from day to day, with any event occurring on board, of spoken vessels, etc. It is transcribed from the *log-board*, and forms the *rough-log* from which (in government vessels) the *smooth-log* is transcribed for the navy department.

Log-chip. (*Nautical.*) The triangular board on the end of the *log-line*. See Log.

Log'ger-head. (*Nautical.*) A runnel on the gunwale of a whaleboat, over which the line passes as it is drawn out by the fish.

Log'ging-axe. An axe used in cutting off logs. It is usually heavier than a *felling* or *lopping* axe. A substitute in the *cross-cut* saw, or the *drag* saw.

Log'ging-head. The working-beam of a steam-engine.

Log-glass. (*Nautical.*) The sand-glass used at heaving the log. Half-minute or quarter-minute glasses are used, according to the rate of sailing. See Log.

Log-line. (*Nautical.*) A line 150 fathoms in length. See Log.

Log-meas'ur-er. A device for gaging logs, taking the round measure with the allowance for the squaring, and giving the results in board measure of the ascertained square in running feet of the log.

Log'o-type. A type having for its face a whole word or a combination of letters in common use; as, *con, com, tion, ing, the, and, in, on*, etc. These com-

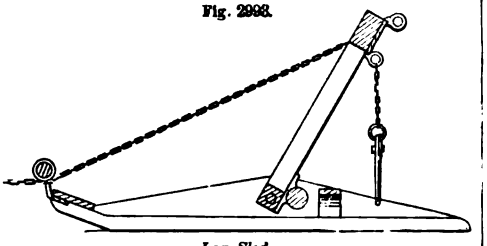
Digitized by Google

pounded types are not now used, but the practice still remains in combinations of letters, such as *ff*, *ffi*.

Log-reel. The reel of the log-line. See Log.

Log-sled. A short, strong, low-benched sled for hauling logs. In the example, the sled has an angular frame provided with trunnions at each end of

Fig. 2993.

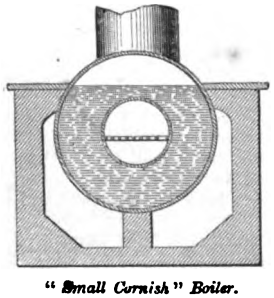


Log-Sled.

its base or lower portion, with bearings in the sides of the sled, and is so connected with a chain and log-hooks that the draft force of the team will act to raise the log and draw it forward upon the sled.

Log'wood. A dyewood obtained from trees of the genus *Hæmatoxylon campeachianum*.

Fig. 2994.



"Small Cornish" Boiler.

Lon'don-boil'er. Also known as the "Small Cornish Boiler." It has a cylindrical fire-tube flue running through it, which contains the furnace and fire-bars. The fire-grate is so arranged with a removable brick bridge, that the whole or any less area of grate can be used that is found most economical.

The current of flame and hot air in this boiler first passes from the fire through the flue-tube to the back end of the boiler, whence it returns under one side of the shell to the front, where it crosses into the other side-flue, through which it proceeds to the chimney in a continuous or *wheel* draft.

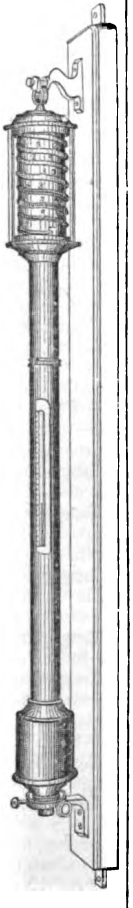
Long-boat. A large ship's boat, from 32 to 40 feet long, having a beam from .29 to .25 of its length. Has a heavy, flat floor, and is sharper in its floor than a *launch*. It is *carvel* built.

Long-bow. (*Weapon.*) A bow the hight of the archer, formerly used in England. See Bow.

Long-cloth. (*Fabric.*) A peculiar kind of fine cotton cloth, made milled or plain.

Long-flax. Flax to be spun its natural length without cutting.

Fig 2995.



Long-Range Barometer.

Long-plane. (*Joinery.*) A joiner's plane used when a piece of stuff is to be planed up very straight. It is 2 feet 3 inches long.

Long-poil. (*Fabric.*) A shaggy velvet.

Long Prim'er. (*Printing.*) A size of type between *Small Pica* and *Bourgeois*.

Small Pica, 83 ems to a foot.
Long Primer, 89 ems to a foot.
Bourgeois, 102 ems to a foot.

Long-range Ba-rom'e-ter. A barometer, the upper portion of whose tube is in spiral form, and of diminished diameter, the distance between the coils being usually 12 base to 1 perpendicular, so that each inch rise of mercury in the tube is indicated by an advance of 12 inches in the spiral coil, admitting of small variations being read without the aid of a vernier.

In another form, the diameter of the tube is diminished at its upper end, and this, with the upper part of the enlarged portion, is filled with a fluid proportionately lighter than mercury. The indications of the latter are thus multiplied in proportion to the difference between the sectional areas of the contracted and enlarged portions of the tube.

Long-ruff'er. A coarse heckle. See Heckle.

Long-saw. A pit-saw; used by a man standing above the log, and one below.

Long-slide. A slide-valve of such length as to govern the ports at both ends of the cylinder, and having a hollow back which forms an eduction passage. It was invented by Murdoch, of the firm of Boulton and Watt. See Cornish Engine.

Long-tack'le Block. (*Nautical.*) A block having two single sheaves, one above the other. The lower one is ⅔ the size of the upper. It is used in combination with a single block, to form long-tackle for loading or other purchase.

Long-tim'ber. (*Shipbuilding.*) A timber rising from the *cants* and continued in one piece to the top of the second futtock.

Long-tom. 1. A kind of gold-washing cradle.

2. (*Nautical.*) A pivot-gun amidship. See Pivot-gun.

Long-valve. A slide-valve found in some of the Watt engines, and which was long enough to cover the ports at both ends of the cylinder. A *long-slide*.

Long-wool. *Combing* wool; in distinction to the shorter, which is carded.

Loobs. (*Mining.*) The slimes of tin ore.

Loo'er. From *Lour* (Fr. *velour*, velvet), a hatter's brushing-pad. See Lure.

Loof. (*Shipbuilding.*) That part of the bow where the timbers begin to *cant* or curve in towards the *stem*.

Look'ing-glass. The old mirror of Narcissus is older than bronze or glass, and the handful of black liquid still holds its place as the mirror of incantations. (See Mirror.) "As in water face answereth to face" (Prov. xxvii. 19) was a comparison adapted to the comprehension of a people who had left Egypt and the arts behind them for a period of near 500 years.

Mirrors to show the full length of the person were known in Greece and Rome. (*Specula totis paria corporibus.* — Seneca.) Pliny refers to glass mirrors with a backing of leaf-metal, made at Sidon.

Looking-glasses were made in Venice, 1298, and in England at Lambeth, 1693.

"Bought a looking-glass by the Old Exchange, which costs me £5 5*s.*, — a very fair glass." — Pepys's *Diary*, 1664.

Looking-glasses are silvered, as it is called, by the following process: A sheet of tin-foil is placed very

Digitized by Google

smoothly on a table or stone, and the foil is then flooded with mercury. The glass is laid upon it in such a way as to expel air-bubbles, and heavy weights are laid on the glass. The weights press out the superfluous mercury, and what remains forms an amalgam with the tin, which adheres to the back of the glass. See SILVERING.

Liebig recommended the following solution for silvering mirrors: —

One part nitrate of silver dissolved in 20 parts pure water. Form a solution of nitrate of ammonia, of a specific gravity of 1.115, and a lye of carbonate of soda, specific gravity 1.035, reduced one third by evaporation. The silvering liquid consists of the ammoniated solution, 100 parts; silver solution, 140 parts; lye, 750 parts. The application of a separate solution causes a deposition of silver on the glass. See also SILVERING-GLASS.

Siemens has modified the operation, as suggested by Liebig, and greatly simplified the reduction of the silver. Dry ammonia gas is passed through aldehyde to produce aldehyde ammonia; 2.5 grammes of aldehyde ammonia and 4 grammes nitrate of silver to 1 liter of water is the proper proportion to take. The nitrate of silver and aldehyde ammonia are separately dissolved in distilled water, mixed, and filtered.

The object to be silvered must be thoroughly cleansed to free it of grease, and if it be a globe or bottle, the liquid is poured in as high as it is desired to form the deposit. As soon as the heat, which must be applied, shows 50° Centigrade, the separation of the silver begins and soon spreads itself over the whole surface. At first, when the coating is very thin, it looks dark, but soon assumes a metallic luster; when it is a brilliant white, it is time to remove the fluid contents, as the mirror is apt to be injured by too long contact with the aldehyde.

Flat objects are laid upon the mixture in the usual manner.

In Germany, where aldehyde ammonia can be purchased at a reasonable cost, this process is highly prized. By making his own salt, in the manner described above, the chemist in this country can also avail himself of the method.

Drayton's method is to employ a silvering fluid made of nitrate of silver, ammonia, and an alcoholic solution of the oil of cassia. This is poured upon the glass, and a reducing fluid of alcohol and oil of cloves applied. This causes a separation of the silver, which deposits itself upon the glass.

Vohl's method of silvering the interior of globes is to cause a precipitation of nitrate of silver by the use of a solution of gun-cotton dissolved in hot caustic potash.

Steinheil uses nitrate of silver, caustic ammonia, caustic soda, milk, sugar, and water. The deposit is pure silver.

Thomson's method, used mostly for silvering the inside of globes and bottles, deposits from an oxide or salt of silver.

Martin's process is quite similar to the last mentioned.

Some looking-glasses have a dark varnish or coating at the back. These reflect only a small portion of the light.

M. Salvetat has announced to the Society of Encouragement, in Paris, a process of preparing looking-glasses, in which tin-foil is replaced by platinum applied in a metallic and brilliant powder. The glass, having been carefully cleaned and polished, is covered, by means of a brush, with a mixture of chloride of platinum, essence of lavender, and a composition of litharge and borate of lead. When dry, the glass is placed in muffles, when the essence, being volatilized, leaves a deposit of platinum dust firmly united to the glass. The new process requires but a few hours. See PLATINIZING.

Dode's plan is to dissolve platinum in nitro-muriatic acid, evaporate to dryness, mix with oil of lavender, take the resulting precipitate, mix with litharge or borate of lead, apply to the glass and bake in an oven.

Lool. (*Metallurgy.*) A vessel to receive the washing of metallic ores.

Loom. A machine in which yarn or thread is woven into fabric.

A woven fabric consists of yarns called the warp laid in one direction, and crossed by yarns laid transversely and known as the *woof*. The *warp* is also called the *chain*. The words *woof*, *weft*, *filling*, are synonyms.

The essential parts of a loom are, —

1. A frame in which the row of yarns forming the warp is held.

2. Leashes or harness which govern the decussation of the threads to form a shed for the *woof*.

Means for holding and actuating, when of the simplest description, may be said to be a *yarn-beam*, to pay off the yarn as the weaving proceeds; a means for operating the *leashes*, by which alternate threads all across the warp are raised and their intermediates lowered, so as to make a decussation (Lat., *decussis* = *decem asses* or X) or crossing known as the *shed*, in which the *woof* is deposited; a means for holding taut the web, so as to keep a proper strain on the warp. A *shuttle* or bobbin for the yarn is usual, but this is not absolute, as a ball of yarn or other filling can be, and is, rolled through the shed. In horsehair and slat looms, the stiff filling is drawn through by fingers, or thrust through, and in some narrow-ware and fringe looms the filling is put in by a rod which goes and returns.

Stripped of its familiarity, weaving is a very ingenious and remarkable process, and many must have been the essays before a serviceable fabric was produced. The preparation of the fiber, its spinning, winding, warping, and weaving, must have had a gradual growth, but with the commencement of historical notices of civilization we find nations in possession of the art.

Egypt excelled in fine linen for ages before Abraham; and the inhabitants of India doubtless spun and wove their cotton before Osymandyas, whose

> "Vast and trunkless legs of stone
> Stand in the desert."

It is natural to conclude that the plants which yielded fiber in bolls, such as the cotton and asclepias, were the first to be utilized, as the uses of flax, hemp, and silk require peculiar preparatory processes. Bark, although used extensively by the natives of some of the islands of Polynesia, has not come into general use for raiment elsewhere; but few trees yield a bark which will make clothing equal to the *tapa* cloth of the Fijis. This is made from the paper mulberry, which grows wild in Oceanica and Polynesia, as well as in parts of Asia. The Fiji group is near the equator, and was discovered in 1643 by Tasman, the Dutch navigator. There are 225 islands, 80 of which are inhabited by a population estimated at 250,000. Paper is also made of the same material (Broussonetia), and specimens are in the Patent Office and Agricultural Department Museum.

The *masi* cloth is made by the same islanders, of the bark of the *malo*-tree. The bark, as removed from the tree, is steeped in water, and beaten on a flat log with a grooved mallet. Two lengths of the wet stuff are beaten together at their edges, being

Digitized by Google

united by their gluten. Separate pieces are united by the starch of the *taro* and then dyed. The mode of uniting is exactly the same as that practiced with the strips of papyrus, as described by Pliny. See PAPER.

The Fijis are strangely cruel, ingenious, and versatile, being the manufacturers for the islanders of other groups, supplying them with canoes, spars, sails, pottery, mosquito curtains, cloth, *sinnet*, rope of *coir* or cocoa-nut husk.

In Captain Cook's time the inhabitants of the Pacific islands had no knowledge of *weaving*, though ingenious in *braiding*, *plaiting*, and *netting*.

Perhaps the earliest examples of weaving were baskets, hurdles, and mats, in which the intersections are exactly the same, though the mode of production is different.

The invention of the loom antedates all authentic history of the Chinese, Hindoos, and Egyptians, and chance references to woven goods are found at an early period of the Old Testament history, as in the case of the "vestures of fine linen" in which Joseph was arrayed by Pharaoh. (See FLAX; LINEN.) The references to woven goods in the Mosaic period are very numerous. The art of weaving was held to have been derived from the early sovereigns of the land; so great regard was felt for the inventor, that the work was generally thus associated.

Semiramis, the Assyrian queen, is credited with the invention of weaving. The Greeks represented Minerva with a distaff, as being the inventress of spinning. Homer refers to the products of the loom. The Egyptians credited it to Isis; the Mohammedans to a son of Japhet; the Chinese to the consort of the Emperor Yao (Noah); the Peruvians to Mamaoella, wife of Manco Capac, their first sovereign.

The modern Arabs and the Hindoos use a procumbent loom. The Bible notices of weaving refer to *loom-work*, *netting*, and *braiding*. 1. When Delilah wove into the web the seven locks of Samson's hair.

2. Where Isaiah pronounces a curse upon Egypt, which shall destroy all her vast works of irrigation and improvement, and "confound" those who live by weaving networks.

The Bible also refers to needlework and embroidery, in the mournful song of the mother of Sisera. See DAMASK.

The mode by which the weavers of India execute the *jamdanee* has been explained by Mr. Taylor as follows: —

"The Hindoo weavers place the pattern, drawn upon paper, below the warp, and range along the track of the woof a number of cut threads equal to the flowers or parts of the design to be made; then, with two small, fine-pointed bamboo sticks, they draw each of these threads between as many threads of the warp as may be equal to the width of the figure which is to be formed. When all the threads have been brought between the warp, they are drawn close by a stroke of the lay or batten; the shuttle is then passed by one of the weavers through the shed, and the weft having been driven home, it is returned by the other weaver."

Pliny accorded the invention of the loom to the Egyptians. The Israelites carried with them the art of weaving when they left Egypt, and in Leviticus (chap. xiii.) the warp and the woof of linen and woolen fabrics are fairly distinguished.

The finest of the linen mummy-cloths of the ancient Egyptians — specimens of which may still be found — have about 140 threads to the inch in the weft and about 64 in the warp.

The looms of Egypt are shown abundantly in the tombs, and the web was either horizontal or perpendicular; the former are shown at Beni Hassan, the latter at Thebes. The woof was sometimes pushed upward, sometimes downward. The product was check or plain. The shuttle was not usual, but the filling was pushed through the shed by a stick or hooked rod. Wilkinson says that some of the colored patterns of the Egyptian cloths were worked by the loom; and others are the result of dyeing and printing processes.

"Colored dresses," says Pliny, "were known in the time of Homer, from whom the robes of triumph were borrowed; and from the Phrygians having been the first to devise the method of giving the same effect with the needle, they have been called 'Phrygiones.' But to weave cloth with gold thread was the invention of an Asiatic king, Attalus, from whom the name 'Attalic' was derived; and the Babylonians were most noted for their skill in weaving cloths of various colors."

It reminds one of the "prey of divers colors of needlework on both sides," in the famous Hebrew song more than thirteen centuries before Pliny, and of the "goodly Babylonish garment" secreted by Achan from the spoils of Ai, 1,500 years before the erudite Roman made his miscellaneous collection of curiosities.

A specimen of an ancient Egyptian rug in the possession of Mr. Hays is described by Wilkinson as made of woolen threads on linen strings, having a central figure in white on a green ground, a border of red and blue lines, and the remainder of it a ground of yellow with figures and ornaments in red, white, and blue. This is but 11 × 9 inches, and may be needlework on linen canvas, with one set of linen strings pulled out, and it cannot be relied upon as illustrative of *loom-work*, though interesting as *embroidery*.

Rugs and mats were the earliest form of carpets, and the early notices of them are frequent and interesting. (See CARPET.) Pliny says: —

"Thick flocky wool has been esteemed for the manufacture of carpets from the very earliest times. It is quite clear from what we read in Homer, that they were in use in his time. The Gauls embroidered them in a different manner from that which is practiced by the Parthians. Wool is compressed, also, for making a felt, which, if soaked in vinegar, is capable of resisting iron even; and, what is still more, after having gone through the last process, wool will even resist fire; the refuse, too, when taken out of the vat of the scourer, is used for making mattresses, an invention, I fancy, of the Gauls." "The *gausapa* [a thick cloth, shaggy on one side, and used for coverlets and cloaks] has been brought into use in my father's memory, and I myself recollect the *amphimalla* [napped on both sides] and the long shaggy apron [*ventrale*] being introduced; but at the present day, the *laticlave* [broad-striped] tunic is beginning to be manufactured into an imitation of the *gausapa*."

"Varro [50 B. C.] informs us that he himself was an eyewitness that, in the temple of Sancus, the wool was still preserved on the distaff and spindle of Tanaquil [wife of Tarquinius Priscus, 616 B. C., and a native of Etruria], who was also called Caia Cæcilia; and he says that the royal waved [watered] toga formerly worn by Servius Tullius [578 B. C.], and now in the temple of Fortuna, was made by her. Tanaquil was the first who wove the straight tunic [*tunica recta*, woven in a perpendicular loom]. Such as our young people wear with the white toga; newly married women, also. Waved [*undulata*, watered] garments were first the most esteemed of all, after

Digitized by Google

which those formed of various colors came into vogue. Fenestella informs us that togas with a smooth surface, as well as the Phrygian togas, began to be used in the latter part of the reign of Augustus. The *pretexta* had its origin among the Etrurians."

"The method of weaving with more than one thread was invented at Alexandria. These cloths are called *polimita*; it was in Gaul that they were first divided into checkers."

Pliny gives the Gauls good credit, — checker-work weaving, the reaping-machine, beer of malt, bread raised by yeast, sieves of horsehair, embroidered rugs; but all *trans Padanus* (Po) seems to have been Gaul with Pliny.

The Greeks and Romans had looms in which the warp was horizontal, and others in which it was vertical, so that the weaver *sat* at work. The box-wood shuttle was of the modern shape, pointed at each end, and had a cavity in which the woof-thread was wound on a stationary pirn or quill, or on a bobbin which revolved as the yarn unwound, and passed through a hole in the side of the shuttle.

The threads of the warp were decussated by a stick (*arundo*), which divided the threads alternately, and the respective sets were passed through the loops of the leashes (*liciæ*) of the harness; the leashes of a given set being attached to a straight rod called a *liciatorium*. The simplest form had one set of leashes, which alternately raised and depressed its set of threads above and below the intervening threads. The number of sets of leashes was increased according to the complexity of the pattern. The woof-thread was beaten up to compact the fabric by a sword (*spatha*) or a comb (*pecten*), like the modern *reed*.

The term *polimita*, signifying "many leashes," and the reference to it by Pliny, indicate that the Greek and Roman looms had harness in which the leashes were arranged in sets to weave twills or patterns, which the Latin terms *bilex*, *trilex*, and the Greek *dimitos*, *trinitos*, *polimitos*, alluding to the degree of complexity of the system, fully confirm.

What the Gr. ἑξάμιτον, or *six-threaded*, may have been it is not easy to tell; but the word is used in connection with a sprig or ornament produced in the texture at regular intervals, and it is probable that it was a six-part harness, floating the woof to make a pattern. The name came down through the ages as ξάμιτον, Lat. *samitum*, O. Fr. *samet*, Ger. *sammet*, Sp. *xamete*, It. *sciamito*, and in our own archaic, —

> "So flashed and fell the brand Excalibur:
> But ere he dipt the surface, rose an arm
> Clothed in white *samite*, mystic, wonderful,
> And caught him by the hilt."

The arts of dressing flax and wool were known in Britain previous to the conquest by Cæsar, who states that the art of weaving was not known by the islanders. However this may be, an imperial manufactory of woolen and linen cloth for the use of the Roman army in Britain was established at Venta Bulgarum, since called Winchester. In Bishop Aldhelm's book, A. D. 680, in an essay on character, occurs a simile from the art of figure-weaving, in which he refers to a "web woven by shuttles, filled with threads of purple and many other colors, flying from side to side, and forming a variety of figures and images." A famous specimen of embroidery of this character is preserved in the Cathedral of Bayeaux. It is a piece of linen about 19 inches in width and 67 yards in length, containing the history of the conquest of England by William of Normandy. It is supposed to have been executed by Matilda, wife of William, and the ladies of her court. Its beauty is principally needlework.

The annexed cut is from Erasmus's book, the "Praise of Folly," and shows the lady of the house

Fig 2996.

A Ladye at her Loom.

at her loom. The cloth-beam, shuttle, and harness are clearly shown.

> "What need we name the sev'ral kinds of looms?
> Those delicate, to whose fair-colour'd threads
> Hang figur'd weights, whose various numbers guide
> The artist's hand: he, unseen flow'rs, and trees,
> And vales, and asure hills, unerring works."
>
> DYER, *The Fleece*, 1757.

Toward the close of the eleventh century, the weavers in the large towns of England were formed into guilds or societies.

In the reign of Richard I. (1197) a law was passed for regulating the fabrication and sale of cloth.

Edward III. encouraged the immigration of weavers and cloth-makers, but the art does not seem to have flourished in England as it did on the Continent, as wool continued to be a staple article of export.

During the persecutions of the Duke of Alva in Flanders, in the sixteenth century, many Flemish weavers settled in England, and introduced or promoted the manufacture of baizes, serges, crapes, and other descriptions of stuffs. The revocation of the Edict of Nantes in 1685 (granted to the French Protestants by Henry IV. in 1598, confirmed by Louis XIII. in 1610, and by Louis XIV. in 1652), by Louis XIV. drove from France many ingenious artisans, who carried with them to England and other countries the arts of silk working, making crystal glass, jewelry, etc.

In weaving plain cloth the threads which run lengthwise of the fabric constitute the *warp*. Those in the direction of the width are called the *weft*, *woof*, *shoot*, or *trum*.

The warp is divided into two parts, each containing an alternate thread, which are alternately raised and lowered, allowing the weft-thread to pass between them through a space termed the *shed*.

The principal working parts of the hand and power loom are the same, comprising a frame, at one end of which is the *beam* or *yarn roll*, on which the warp-threads are wound, and at the other the *cloth-beam* on which the finished cloth is wound. The means for paying off the yarn from one beam and winding the cloth on to the other are known as the *let-off* and *take-up* respectively.

Each half of the warp is alternately raised and lowered by means of the *healds* or *heddles*, threads

Digitized by Google

having loops at their lower ends and attached above to two horizontal rods connected by a pulley, the whole collectively constituting the *harness*, so that when one heald rises the other falls. Each warp-thread passes through one of these loops. The warp-threads also pass through the *dents* or teeth of a *reed* at the lower part of a movable swing-frame called the *lathe*, *lay*, or *batten*, which beats home and compacts the warp-threads as the work progresses.

The bottom of this frame has a projecting ledge, forming a path for the *shuttle* which contains a *cop*, on which the weft-yarn is wound.

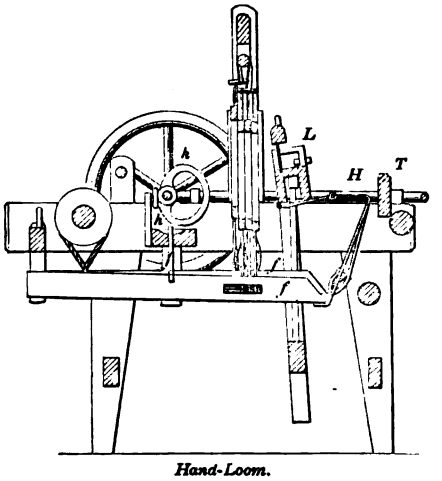
The shuttle in hand-looms is thrown across the race by hand or by means of the *fly*. When the latter is used the two ends of the shuttle-race are closed, so as to form a trough in which two pieces of wood, called *pickers* or *peckers*, are caused to move along wires. A string from each picker is attached to a handle which the weaver holds in his right hand, and by means of a smart jerk he propels the shuttle back and forth along the race. The weaver is seated at the end of the loom next the cloth-beam, and by pressing with his foot on one of two treadles he raises one of the *healds*, and with it one set of warp-threads. The shuttle is then thrown, passing through the shed between the two sets, and the weft-thread is driven home by the batten, which the weaver guides with his left hand. The other treadle is now depressed, raising the other set of warp-threads, the shuttle thrown back to its first position and the weft-thread beaten home as before. In this manner the weft-thread is caused to pass alternately above and below the threads of each of the two sets composing the warp until the work is completed. When a few inches of cloth are woven it is wound upon the cloth-beam.

In order to prevent the cloth from contracting in breadth before being wound on the cloth-beam, two pieces of wood with sharp-pointed ends, which are inserted in the selvage of the cloth, are employed. This stretcher is called a *temple*.

Previous to being wound on the yarn-beam, the warp-yarns require to be laid side by side in one plane. This is effected by a device called the WARPING-MILL (which see).

In Fig. 2997 is shown an improved hand-loom,

Fig. 2997.



Hand-Loom.

operated by a crank on the shaft *H*. The warp-roller is at the left and the cloth-roller at the right of the machine. The harness-frame carries four heddles, which are actuated by the revolution of the cams *h h*, acting on levers *f f* connected to the heddles. *L* is the shuttle-box on the lay, and *T* the breast-beam. A fly-wheel on the same shaft with the cams equalizes the motion. The cams are so arranged on the shaft as to act in the required consecution to produce the twill or pattern required, and by increasing the number of cams and heddles a variegated recurrent pattern of considerable complexity may be produced. The revolution of the crank gives all the motions of the machine, — heddles, shuttle, and batten. (See HAND-LOOM.) In other forms of hand-looms the motions are derived from the vibration of the batten.

A positive motion has been given to the shuttle in place of the fly motion, on several occasions. Once in Greenough's circular loom, and again in Lyall's reciprocating loom. In the latter case, the shuttle is conveyed through the shed by a carriage which is impelled by cords, which are wound upon a reciprocating drum beneath the frame. The carriage and the shuttle have rollers which move in contact with the yarn, so as to have a rolling but no rubbing action. The rotary motion of the rollers in the carriage is transmitted through the warp to the lower rollers of the shuttle, as the threads of the warp pass between the two.

The earliest power-loom on record was contrived by a French naval officer, M. de Gennes, and is described in the "Journal des Sçavans," 1678. The inventor claimed that a single mill could give motion to 10 or 12 looms, and that cloth could be made by their means much wider than by the ordinary loom then in use. It does not appear to have been a practical working apparatus, and never came into use.

We are indebted to Dr. Edmund Cartwright for the first practical power-loom. He was a minister of the gospel, and unacquainted with mechanics; but had his attention turned to the subject by a remark, that when Arkwright's patents expired so many persons would go into the spinning business that no hands would be found to weave the cotton. He declares that his first attempt was a most rude piece of machinery. "The warp was placed perpendicularly, the reed fell with the weight of at least half a hundred weight, and the springs which threw the shuttle were strong enough to have thrown a Congreve rocket." It required the power of two men to work it. He secured his patent April 4, 1785. He then went for the first time to see how other people wove, and was astonished at the comparative clumsiness of his own contrivance. He went on improving, and took out his last patent 1787. He met with the trouble incident to great inventors, — an ignorant populace and rich pirates. He spent £30,000 in his endeavors to perfect his loom, and in 1808 received a Parliamentary grant of £10,000 for his great national services. On this sum he retired to a farm in Kent, and spent his declining years in comfort, occaionally trotting out his hobbies. He died in 1823, aged 80.

Steam was applied to his looms in 1807.

Fig. 2998 shows the working parts of a power-loom, the framing being omitted.

The warp *a* is wound upon the warp-beam *b*, and, passing over the roller *c*, is carried through the two healds *d d*, which alternately raise and lower the two sets of warp-threads, forming the shed for the passage of the shuttle. The shuttle is driven along the shuttle-race *e* by a kind of hammer *f*, worked by a lever *q* moving through a small arc of a circle. The finished cloth is kept tight by the temples *h*, a portion being wound on the cloth-beam *i i*.

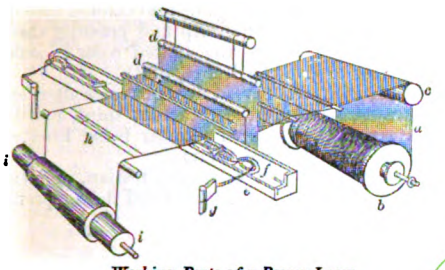
Fig. 2998.



Working Parts of a Power-Loom.

In the power-loom, five distinct actions are performed by steam-power.

1. Raising and lowering alternately the two sets of warp-threads.
2. Throwing the shuttle.
3. Driving up each weft-thread after the shuttle is thrown.
4. Unwinding the warp from the beam.
5. Winding the cloth on the cloth-roller.

An arrangement is also introduced for stopping the loom when a thread breaks, when the shuttle sticks in its passage, or when the yarn on the cop contained in the shuttle has run out. This may be effected in various ways, depending on the nature of the loom.

Fig. 2999 represents an improved power-loom. *a* is the frame, *c* is the warp-beam, and *e* the cloth-beam; *k w*, the lay. The heddles are actuated by cams *h* acting on the levers *g*, to which they are connected. On the same shaft is the scroll-cam *w'*, in which traverses a roller imparting a vibratory motion to the lay, in which is a raceway for the shuttle.

Looms for "Domestic" Cottons and for Linens

Fig. 3000 is a perspective view of a *warping-machine*, *winding-machine*, and a *loom* for light and medium cotton goods.

Fig. 3001 is a perspective view of two looms, one for "domestics" and heavy cotton goods, the other, on the right of the picture, for linens.

With the modern power-loom, the cost at Manchester of weaving a piece of cotton cloth 25 inches wide, 29 yards long, and 11 picks per ¼ inch, is estimated at 10¼ cents. One person can attend

Digitized by Google

to two or three looms, and each loom produces 26 pieces of such cloth per day.

On the old hand-loom of 1800, one man would attend to one loom, and would produce 4 pieces at an expense of 66 cents each.

In plain cloths the warp and weft threads are of about equal fineness. Yarns of two different sizes introduced into the web produce a sort of striping. When the warp and weft threads are of different colors a shot pattern is produced.

Striped patterns are formed by introducing at regular intervals the different colored threads required; checks, by inserting different colored threads at proper distances in the warp and crossing them in the weft by threads of the desired color in sufficient number to give the desired width.

In twills, each weft-thread does not cross alternate warp-threads, but only the recurrent third, fourth, fifth, or sixth, the required number being inserted through each heald. See TWILL.

Piled work, as velvet, velveteen, fustian, or piled carpet, is formed by introducing a third thread, previ-

Fig. 3002.

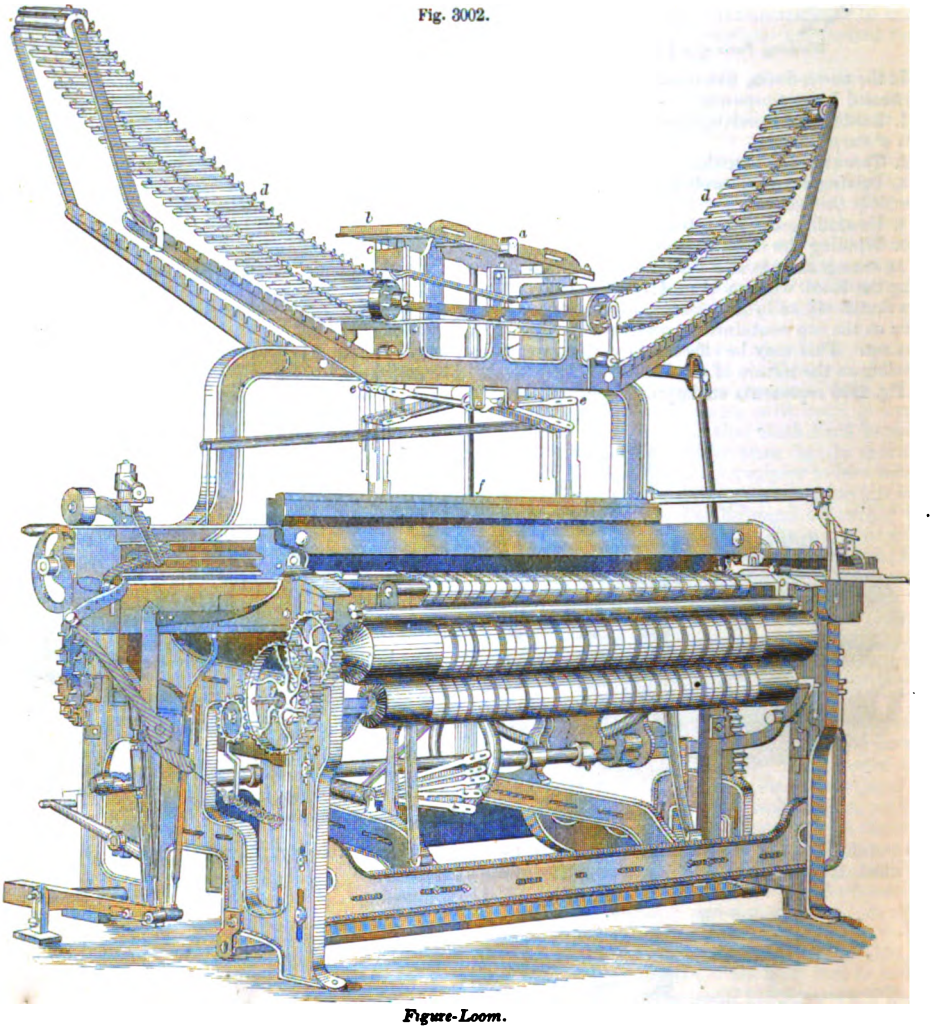

Figure-Loom.

ously looped by weaving it over wires the breadth of the fabric. In some kinds these are cut out with a knife, in others they are simply withdrawn from the loops.

One mode of making goods in patterns of colored figures is by means of a variety of shuttles, each carrying its own colored thread. These shuttles are arranged in a box which may be raised or lowered, so as to bring the required shuttle opposite to the picker which drives through the shed. This motion of the shuttle-box is obtained by means of a PATTERN-WHEEL or PATTERN-CHAIN (which see).

Figures, previous to the invention of Jacquard, were formed in the *draw-loom*.

In this, the warp-threads were arranged in separate groups so disposed as, in conjunction with the weft-threads, to form the figures. The proper succession of the weft-threads as to color, etc., was arranged by the weaver, several shuttles being employed, if necessary. For this purpose, a pattern-card was provided, to which the workman could constantly refer. Each set of warp-threads was attached to a handle by which they were drawn up at the proper time by an attendant called a *draw-*

Digitized by Google

boy. This involved liability to mistakes, deranging the pattern, and to obviate this a mechanical draw-boy was invented.

Jacquard's ingenious invention superseded this, producing an entire revolution in the art of figure-weaving.

Joseph Maria Jacquard was born at Lyons, 1752; invented his loom for weaving figured fabrics in 1801; and died at Orleans in 1834.

The action of the Jacquard in producing patterns upon fabric may be briefly described as follows: —

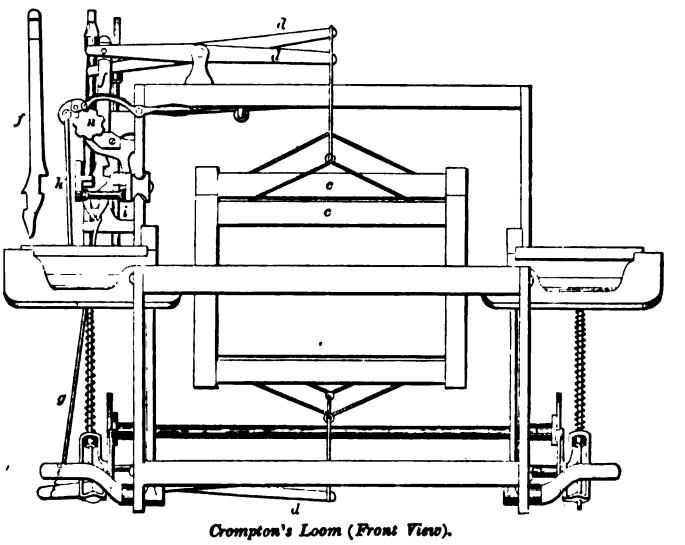
To the ordinary looms perforated cards are added, through which certain needles pass, causing the threads to rise and fall, according to the holes in the cards, thus reproducing upon the tissue in the loom the pattern which is perforated in the card. See JACQUARD LOOM.

Fig. 3002 is a view of an English power-loom for fancy weaving, having what is called a *dobby*, with the harness controlling mechanism.

The pattern-chains *d* are mounted in a frame at the top of the loom, and in their movement their pins act on vertical hooked wires or jacks *c*, connected with a series of coupled levers *e*, connected in turn with the harness-frames *f*. A rocking frame *a* at the top of the loom, provided at its opposite ends with cross or griff knives or bars *b*, engages the hooked wires selected by the pins of the pattern-chains, and raises the harness-frames necessary to produce the pattern. Plain and fancy twills, spots, satin checks, etc., may be produced. The loom also shows changeable shuttle-boxes.

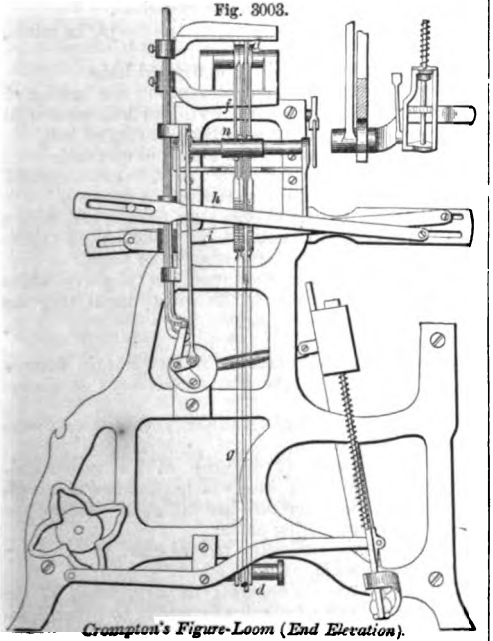
One example of Crompton's looms is given in Figs. 3003 and 3004, the former being an end elevation and the latter a front elevation.

Fig. 3004.



Crompton's Loom (Front View).

Fig. 3003.



Crompton's Figure-Loom (End Elevation).

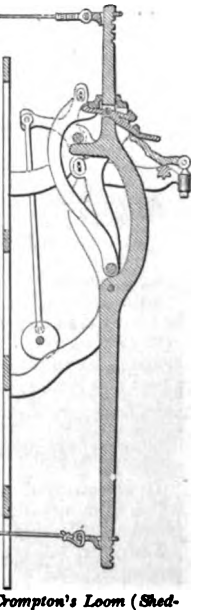
The harness-frames *c* are attached by cords or wires to horizontal top and bottom levers *d*, whose opposite ends are connected by means of notched jacks *f* and wires *g*. The notched jacks are moved by pins on a pattern-cylinder *n*, so that their notches are engaged by either the lifter or depresser *h i*, to raise or lower the harness-frames. This loom has also shifting shuttle-boxes, and the box-lever is moved by a star cam.

On the left of Fig. 3004, one of the jacks *f* is shown on an enlarged scale to exhibit the notches more clearly.

In another variety of Crompton's loom (Fig. 3005), vertical levers pivoted at the side are connected at bottom and top to the heddle or harness-frames by cords, and notched jacks pivoted to such vertical levers and controlled by a pattern-cylinder are engaged by bars which move the levers and open the shed, these bars acting as lifters, depressers, and eveners. The figure shows the motion work merely.

In Short's loom for weaving fabrics of any width, the shuttles are carried through the shed by a belt having a continuous motion. This is supported on a carriage with small anti-friction rollers traversing the raceway when it is swung as a batten. A shuttle is engaged by a lug on the belt, and, after crossing the shed, deposited in a chan-

Fig. 3005.



Crompton's Loom (Shedding Motion).

Digitized by Google

nel in the frame, when the belt engages another shuttle and carries it across in the opposite direction.

The number of patented inventions relating to looms and their appliances, both in this country and England, many of them of slight importance, is too great to give even a brief idea of here. Some of the more important will be found under their specific heads. See WEAVING.

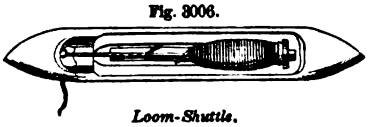
2. (*Nautical.*) The part of the length of an oar inside the gunwale in rowing. In contradistinction to the *blade*.

Loom-card. (*Weaving.*) A pierced pattern-card for Jacquard weaving.

Loom-har'ness. (*Weaving.*) That portion of the loom by which the warp-threads are moved to make the decussation, forming the shed in which the shuttle travels and leaves the weft-thread. The harness has heddles with loops for the warps, and a part are raised above the others, either in regular alternation for plain weaving, or in other order, according to the pattern. See LOOM; TWILL.

Loom-shut'tle. One for carrying the *weft*-thread through the *shed* formed by the decussation of the warp. An orifice is made through the shuttle

Fig. 3006.



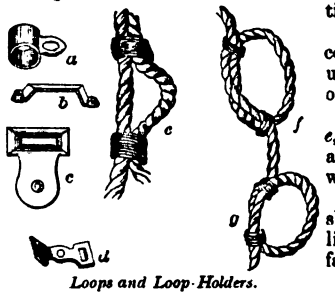
Loom-Shuttle.

in line with the yarn-eye, and another through the bottom at the same distance from the end. There are many varieties.

Loon'ghie. (*Fabric.*) A silk and cotton cloth of rich color, made in Sinde, in pieces about 4 yards long and 2 feet wide.

Loop. 1. (*Machinery.*) A slotted bar which forms a guide and limit to the motion of an object.

Fig. 3007.



Loops and Loop-Holders.

2. A sleeve or collar *a*, as that upon the middle of a neck-yoke.

3. (*Nautical.*) *e*, a bastard loop; a rope stopped with yarns.

f is a loop for slipping other lines, acting as a fair-leader.

g, a bend stopped with seizings.

4. A hinge of a door or gate.

5. A panel of bars joined together like a gate, to be removed in and out at pleasure.

6. (*Telegraphy.*) A wire going out and returning to the same point, as to a branch office, and forming a part of a main circuit.

7. (*Metallurgy.*) A mass of iron gathered into a ball on the floor of a reverberatory furnace, and in a pasty condition ready for the tilt-hammer or rolls.

It is conveyed by dragging on the iron plates which form a track on the floor, or in a little truck called a *ball-trolly*. A *loup*.

Loop'er. A perforated blade or bodkin for inserting the end of a carpet-rag through the end of another piece, looping them together to avoid the trouble of sewing.

Loop-hold'er. A carriage-iron (*b c d*, Fig. 3007) by which the *loop* of a strap is attached to running-gear or the bed.

Loop-hole. (*Fortification.*) An aperture or slit in a stockade or other defense, from whence musketry may be fired at assailants. Machiolation, embattlement, embrasure, crenelle.

Loop-line. 1. (*Railway Engineering.*) A connecting line of railway; one running into the trunk.

2. (*Telegraphy.*) A wire going out and returning to the main circuit. A *loop*.

Loos'en-ing-bar. (*Founding.*) A stiff bar with a point or screw which stands in a hole in the pattern, and extends upward through the top box. After ramming up, and before lifting the top part, this bar is struck alternately from opposite sides with a short, heavy piece of iron, so as to loosen the pattern slightly in the sand, after which it is removed. This operation facilitates the separation of the sand from the pattern, and lessens the amount of mending required. See MOLDING.

Loose-pul'ley. (*Machinery.*) A pulley running loosely on the shaft, and receiving the belt from the *fast-pulley* when the shaft is to be disconnected from the motor.

Lo'per. (*Rope-making.*) The swivel at the end of a ropewalk remote from the *whirl*, and to which the ends of the yarns are attached when laying up several yarns into a rope. As the twisting proceeds, beginning at the remote end, the *top* which holds the strands apart is gradually advanced towards the *whirl*.

Lop'ping-axe. A light axe used for trimming trees. The term may be considered as in contradistinction to *felling-axe* or *logging-axe*.

Lop'ping-shears. A pair of heavy shears for trimming bushes, hedges, etc.

Lor'cha. (*Nautical.*) A light Chinese coaster having a hull of European model and Chinese masting and rigging.

Lor-gnette'. An opera or spy glass.

Lor'ry. A handcart used on tramways, in mines, or at railway stations.

Losh-hide. An oiled, undressed hide.

Lost-mo'tion. The difference in the motion of a driver and a driven part, owing to looseness of fit of boxes, the connecting portion, or slip of belt.

Lounge. A sofa with a back and one end.

Lou'vre. (*Architecture.*) *a*. A turret on a roof for the escape of smoke or steam. A *lantern*.

b. Sloping boards overlapping each other, with a space between for ventilation. Also called *louver-boarding*; *louvre* or *louver* window or work.

Low-bell. 1. A bell used to slightly alarm birds and cause them to lie quiet, until they are flushed by a sudden noise.

2. A *sheep-bell*.

Low-blast Fur'nace. A metallurgic furnace in which the air of the blast is delivered at moderate pressure.

Low'er An'chor. (*Nautical.*) One down stream for anchoring boats.

Low'er Case. (*Printing.*) *a*. The case standing below the upper case which contains the capitals, etc. The lower case has the small letters, the points, and some other sorts.

b. The letters belonging to said case.

Low'er Deck. See DECK.

Low'er-ing. (*Printing.*) A depression of the face of a type or woodcut to cause it to print lighter. The removal of the thickness of the tympan in the appropriate spots assists in producing the required effect.

Low-press'ure En'gine. (*Steam-engine.*) In

Digitized by Google

England, one in which *a condenser is used*, and whose safety-valve is loaded at from *four to six* pounds to the square inch. — LARDNER.

The terms *high* and *low pressure* steam were formerly held to mean saturated steam at a pressure above or below that which will sustain a column of thirty inches of mercury; the boiling heat of water, 212° of Fahrenheit.

The term *low pressure* signifies in this country a pressure of not over fifty pounds to the square inch.

Low-re-lief'. The slight prominence of a sculptured object from the plane surface to which it is attached. Also known as *basso-rilievo*.

Low'ry. (*Railway Engineering.*) An open box-car.

Low-wa'ter A-larm'. The devices for this purpose may be classed under four heads.

1. Those in which a float in the boiler subsides with the water, and is the means of opening a feed-valve, turning a steam-cock to the whistle, and indicating on a dial the condition of the boiler.

2. Those in which the subsidence of the water uncovers the end of a pipe, and admits steam to a rod or tube whose increment of heat and consequent expansion operate mechanically upon a valve, and allow steam to pass to a whistle.

3. Those in which steam admitted to a pipe, as just stated, melts a fusible plug, and so allows steam to pass to a whistle.

4. Those in which the subsidence of the water uncovers the end of a pipe and allows water to flow from a reservoir on the end of a lever, the steam from the boiler occupying the place thus vacated. The change of weight incident to the substitution causes the motion of a lever, which is made to open a valve or turn a stop-cock and emit steam to the alarm-whistle.

1. The *float movement.*

A. The float is attached to an arm, and is immersed in water in the chamber which communicates by pipes with the boiler. Should the end of the lower pipe be uncovered by the subsidence of the water to that level, the water leaves the chamber and the float falls, depressing the valve and admitting steam to the whistle. When the water rises again, the upper valve is moved to allow steam to depart, and the normal condition is re-established.

B. The hollow steam-tight case has a central hub and a sector space, occupied by the arm of a float, which rises and falls with the changes of level of the water in the boiler. An indicator on the same axis moves with the float.

C. A float is placed on the crank-arm of the valve-stem, and rises and falls with the changes of the water-level, bringing a stud on the stem against an inclined socket, and raising the valve from its seat. This allows steam to pass to the whistle.

2. The *thermostat movement.*

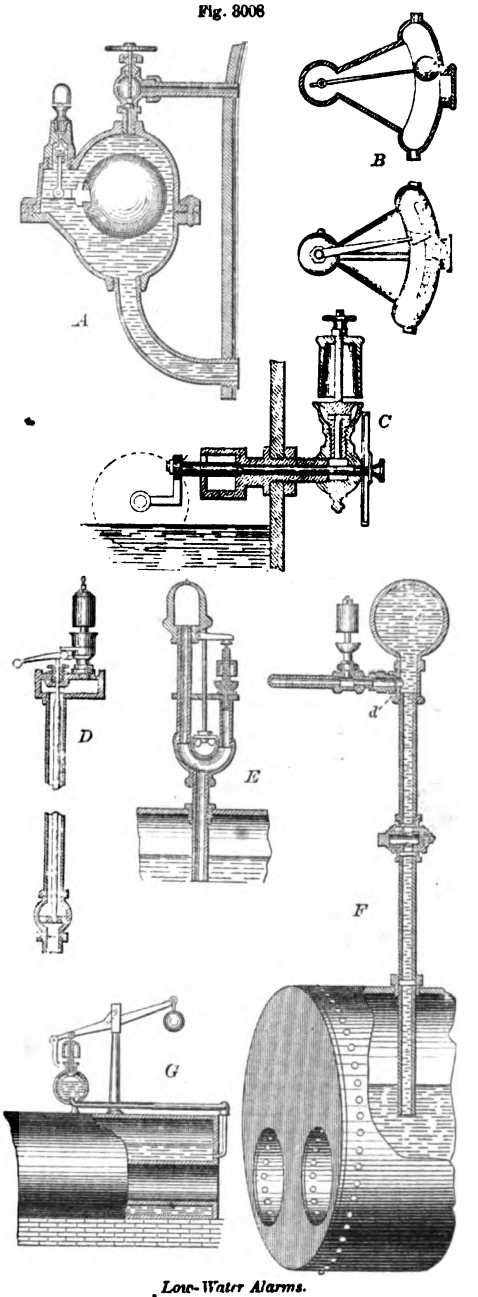
D. When the water subsides below the end of the vertical pipe, which extends downward into the boiler, the water contained therein is discharged and steam substituted. The increased heat, due to the presence of steam, elongates the thermostatic rod in the tube and acts upon the lever to lift the valve from its seat; the steam rushes out and sounds the whistle.

E. This acts similarly to the foregoing, except that the effect is due to the expansion of the steam-pipes when the water is emptied and steam admitted. The lever has its fulcrum on a post between the pipes; the expansion of one of the latter depresses the valve-stem and withdraws the valve from its seat; the expansion of the other pipe withdraws the seat from the valve. The action of the two is cumulative. The passage of steam sounds the whistle, as in other devices for the same purpose.

3. The *fusible-plug action.*

F. After the boiler has been filled to the water-line and put in operation, the pressure of the steam

Fig. 3008



Low-Water Alarms.

forces the water into the pipe and air-chamber *c*. As there can be no circulation of water in the pipe as long as the lower end of it is under the water-line, the *disk d* will continue solid; but when the water in the boiler evaporates below the end of the pipe to

Digitized by Google

the alarm water-line, then the water in it falls of its own weight into the boiler, and steam at once takes its place, melts the plug, and notice of low water is given by the sounding of the whistle.

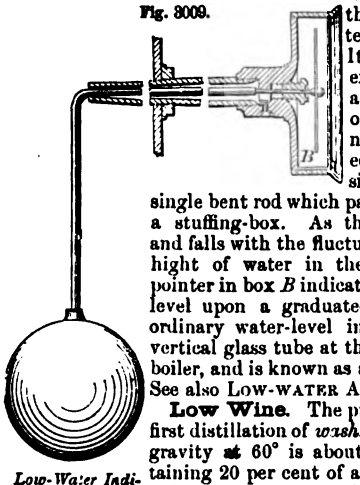
There are many variations of the fusible-plug device, some depending upon the direct heat of the steam, and others, as above, upon the admission of steam to a pipe which is normally charged with water.

4. The *gravity movement.*

G. A vertical pipe passes into the boiler, and its open end is at the level at which it is desired notice shall be given. This pipe forms a communication between the boiler and a reservoir on the end of a hollow arm and axis. In the normal condition this reservoir is filled with water; but when the end of the pipe is uncovered by the subsidence of the water-level in the boiler, the water runs out of the reservoir and steam takes its place. The change of weight in the reservoir, due to the substitution of steam for water, causes the arm to be lifted by the weighted lever and raise the valve which admits steam to the whistle.

Low-wa'ter In'di-ca-tor. An attachment to a boiler to show the depth of water in the boiler. It may, as in the example, be an arrangement of float and needle mounted upon opposite ends of a single bent rod which passes through a stuffing-box. As the float rises and falls with the fluctuations of the hight of water in the boiler, the pointer in box *B* indicates the water-level upon a graduated arc. The ordinary water-level indicator is a vertical glass tube at the end of the boiler, and is known as a *water-gage.* See also LOW-WATER ALARM.

Fig. 3009.



Low-Water Indicator.

Low Wine. The product of the first distillation of *wash.* Its specific gravity at 60° is about 0.978, containing 20 per cent of alcohol.

Loz'enge. 1. An oblique-angled parallelogram. A *rhomb.* A *diamond.*

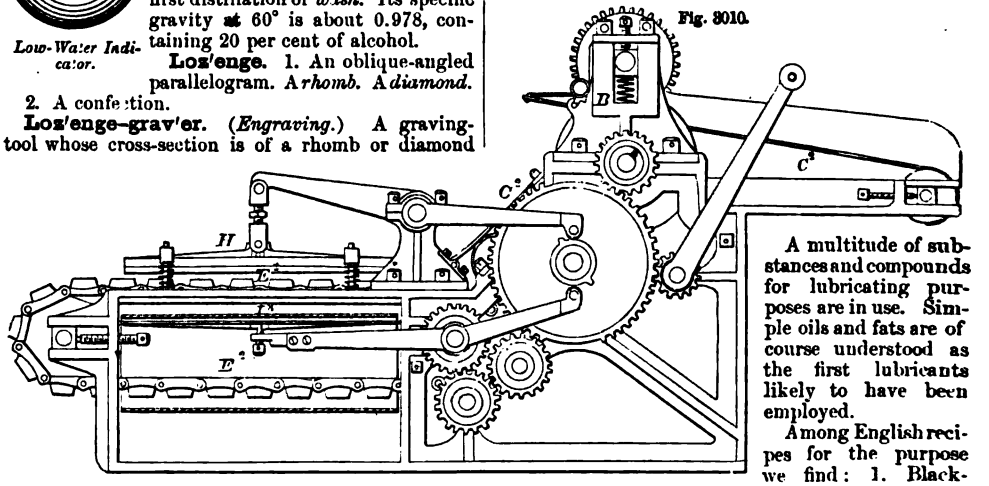
2. A confection.

Loz'enge-grav'er. (*Engraving.*) A graving-tool whose cross-section is of a rhomb or diamond shape. The two faces which meet to form the belly of the graver have an angle less than 90°.

Loz'enge-ma-chine'. A machine for rolling out and cutting lozenges, crackers, etc.

In the machine shown in Fig. 3010, *dough* is rolled out to the required thickness by passing between rollers *B*, follows the endless band C^2, and passes over the perforated cutters E^2. Here the feed is stopped, and the platen *H* falls on the dough, forcing the lozenges down upon an endless belt I^2. When the platen rises, the unused *dough* is carried to the end of the machine by the forward motion of the cutters, and returned to the rolling-cylinders by an attendant.

Fig. 3010.



Lozenge-Machine.

Loz'enge-mold'ing. (*Architecture.*) An ornament inclosing diamond-shaped panels.

Lub'ber's-hole. (*Nautical.*) An opening in the floor of the *top* for those to crawl through who are afraid to climb up by the *futtock-shrouds.*

Lu'bri-cant. A substance used to diminish friction of the working parts of machinery.

According to M. Morin, the friction of a cast-iron shaft upon a dry bell-metal bearing amounts to nearly one fifth of the power transmitted, while with a wrought-iron shaft friction absorbs more than one fourth. When well lubricated, the loss is reduced to .065 and .09 respectively.

The requisites of a good lubricant are that it must endure the heat even of melted lead, without change, in order to stand friction and lubricate the cylinders of steam-engines. (The heat under a pressure of 150 pounds of steam is enough to decompose or distill and dry up most of the natural oils in market.) They must be fixed and not volatile oils, as produced by destructive distillation, otherwise they are decomposed by friction, and burnt or dried up. They must not show or possess any acid reaction, either naturally or artificially, otherwise the bolts are cut in the steam-chest, and the iron, particularly wrought-iron, is made porous. They must possess a sufficient power of tenacity without oxidation, otherwise they will gum.

The same laws are applicable to signal and burning oil, for it makes no difference whether the oil is subject to immediate heat, as in a lamp or steam-cylinder, or whether it is slow and long continued, as in slides and other bearings, the effect and result are the same in the end upon the oil.

A multitude of substances and compounds for lubricating purposes are in use. Simple oils and fats are of course understood as the first lubricants likely to have been employed.

Among English recipes for the purpose we find: 1. Black-lead, 1; tallow 4. Mix and grind perfectly smooth. Add beeswax for railroad carriages.

2. (Booth's.) Scotch soda, 1 pound; boiling water, 2 gallons; palm-oil or tallow, 10 pounds. Agitate till the mixture is cooled to 65° Fah.

Digitized by Google

3. (Mankettrick's.) Caoutchouc dissolved in oil of turpentine, 4 pounds; Scotch soda, 10 pounds; glue, 1 pound; dissolve in water, 10 gallons; oil, 10 gallons. Stir, adding caoutchouc last.

4. Rape-oil, 1 gallon; caoutchouc (cut small), 3 ounces. Dissolve with heat.

The following compounds have been used in America: —

Resin, flowers of sulphur, antimony, oil rosemary, lampblack, water, carbonate of iron, sheep's tallow.
Animal oil, palm-oil, paraffine.
Asbestus, graphite.
Palm-oil, tallow, borax, salt, water.
Soapstone, petroleum, sulphur, antimony, oil.
Lampblack, petroleum.
Coal-oil, isinglass, Irish moss, glue.
Caustic soda, tallow, petroleum, animal hair.
Paraffine, resin, cotton waste.
Tallow, sulphur, soapstone.
Petroleum, plumbago, beeswax, mutton-tallow, soda.
Lime, chalk, carbonate of potash.
Leather boiled in carbonate of soda, oil, sulphuric acid.
Water, salts of niter, sulphur, soft soap, salt pork.
Borax and oil.
Petroleum residuum, alkali, ammonia, saltpeter.
Graphite, oil, caoutchouc.
Asbestus and grease.
Lignum-vitæ, spermaceti.
Ivory dust, spermaceti.
Tin and petroleum.
Zinc and caoutchouc.
Plastic bronze and caoutchouc.
Boiling water, tallow, palm-oil, salts of tartar.
Oil, lime, graphite, castor-oil.
Shorts, soapstone, graphite.
Coal-oil residuum, chloride of sodium, hydrated potassa, muriate of ammonia, spirits turpentine, linseed-oil, flowers of sulphur.
Petroleum residuum and flour.
Petroleum residuum, soapstone, sulphur, and lard.
Mixed heavy and light petroleum.
Oil, wax, resin, india-rubber, potash.
Petroleum residuum, sal-soda, brimstone, kerosene.
Glycerine, graphite, asbestus, kaolin, manganese, steatite, sulphide of lead, carbonate of lead, cork.
Saponified resin, wheat flour, middlings, petroleum, animal fat, soda.
Type-metal and caoutchouc.
Anthracite coal and tallow.
Oxide tin, beeswax.
Soapstone, magnesia, lime, oil.
Sulphur, petroleum.
Vulcanized rubber, petroleum, tallow.
Paraffine, oil, milk of lime.
Asbestus, tallow.
Spermaceti, india-rubber.
Tallow, petroleum, soda, hair.
Mercury, bismuth, tin, antimony.
Crude petroleum, sal-soda, lime, tallow, lard, salt, pine-tar, spirits turpentine, camphor, alcohol.
Sulphur, plumbago, mica, tallow, oil.
Palm-oil, paraffine, tallow, alkali, asbestus.
Tallow, oil, paraffine, lime-water.
Flaxseed-oil, cotton-seed oil, lime-water, tallow.
Petroleum, tallow, beeswax, soda, glauber's salts.
Animal-oil, croton-oil, spermaceti, tallow, soda, potash, glycerine, ammonia.
Mica.

Sheets of paper or of fabric, impregnated with graphite, steatite, paraffine, tallow, size, or soluble gums, are used for lubricating.

The best lubricant for bullets was found by the Springfield Board to consist of eight parts bayberry-wax and one part graphite. Japan wax is often used with graphite, but with inferior results.

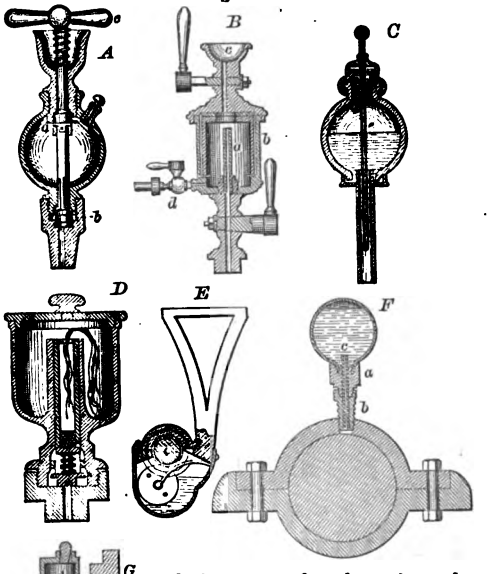
Graphite cannot be made fine enough for lubricating purposes if separated by bolting, but must be separated by floating either in water or air. The simplest method is the water separation, and during the process it should be treated to a bath of dilute sulphuric acid, which will take up the particles of spar and iron, leaving the sulphates of lime, magnesia, and iron easily washed out. The mode of floating and settling to obtain the powder of ultimate fineness is described under PENCIL. For the finest pencils, for lubricating and for electrotyping, the mineral should be in impalpable condition.

Lu'bri-ca-tor. 1. (*Steam-engine.*) An oil-cup or other contrivance for supplying oil or grease to rubbing surfaces, in order to diminish friction. The number of patented devices of this kind is large. A few are shown in Fig. 3011.

In *A* the two valves *a b* are connected by a rod. By turning the handle *e* in one direction the valve *a* is depressed by means of a pin working on an inclined plane, and admits oil to the reservoir. A reverse motion opens the valve *b*, furnished with a similar contrivance, permitting the oil to flow from the reservoir. The valve *a* is kept to its seat by a spiral spring on the rod.

B. Steam is admitted through the pipe *a* to the oil-chamber *b*, forcing out the lubricating material through an opening to the desired point. The supply of oil from the cup *c* is regulated by a cock, and a cock *d* at the side of the oil-chamber permits accumulating water of condensation to be drawn off. The oil-chamber is of glass, protected by a metallic casing.

Fig. 3011.



Lubricators for Machinery.

C. The central tube *c* is open, and when the oil sinks below its lower end air is admitted through it and the annular passage to the reservoir above, and allows an equivalent amount of oil to descend. The vertical adjustment of the tube regulates the flow by determining

Digitized by Google

the hight of the column of oil resting upon the journal.

D. The oil is conducted from the annular reservoir by a wick of fibrous material into the tubular valve-stem. This stem has radial holes at its lower end for the discharge of oil, and wire-gauze to arrest impurities. Between the upper and lower valves is a spiral spring. When the engine is running, the valves are closed by steam and spring pressure; when stopped, the upper valve is closed by the spring, and when running without steam both valves are sucked open and the oil flows.

E. 2. (*Shafting.*) A pivoted disk in a cup below the lower journal-box is revolved by contact with the under side of the shaft *c*, and carries up oil to lubricate the latter. See also SHAFTING; JOURNAL-BEARING.

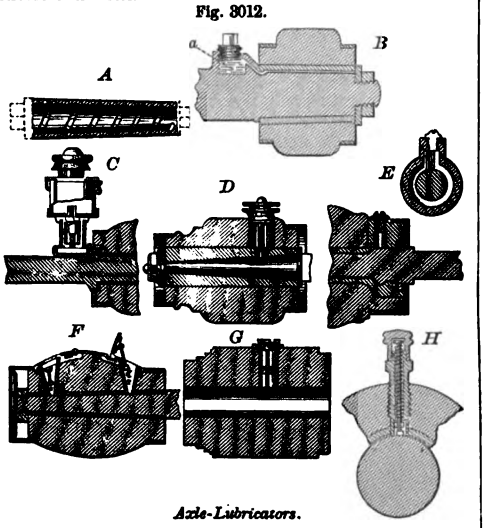
F has a transparent reservoir with metallic socket *a* screwing into the seat *b*, fitted to the cap of the journal-box. Between this and the journal is a slight vacuity, from which air is admitted through the tube *c*, allowing a greater or less quantity of oil to flow in proportion as the journal turns more or less rapidly. When at rest the flow ceases.

G. The flow of oil from the cup *A* is regulated by an adjustable screw-plug. The bearing has ducts for conveying surplus oil from the upper part of the shaft toward the center, and at its lower part is a closed chamber forming a drip-cup.

3. (*Vehicle.*) The ordinary mode of lubricating carriage or wagon axles is by placing grease on the spindle and then putting on the wheel, giving it a few revolutions before lowering it again to the ground. The grooves in the box of the hub form pockets in which the grease collects, and from which it passes to the spindle as it gradually wastes away. Many patents have been granted for devices in the boxes for retaining the lubricant, and are cited under AXLE-BOX.

In Diller's (*A*, Fig. 3012), a spiral groove is formed around the inner surface of the box, and leads the grease to all parts of the spindle, while the integrity of the bearing-surface of the box is not materially interfered with.

Fig. 3012.



Axle-Lubricators.

The lubricating devices are attached to the spindle or axle, or to the hub of the wheel. Of the former, two will be cited as representatives of their section of this class.

Those attached to the hub are the more numerous.

B. The reservoir *a* is closed by a screw-plug, which is turned to force the oil through a duct leading to a groove in the upper part of the spindle. The groove tapers toward the outer end, so as to distribute the oil equally.

C. A *lantern* is attached to the axle of the carriage just inside of the butting-ring. The oil-reservoir, besides furnishing supply to the wick of the lantern, also supplies oil through a duct to the bearing surfaces.

D. A tube passes radially through the hub, its lower end opening into the interior space of the box. The oil-reservoir is covered by a screw-cap. The inner end of the tube is closed by a valve whose stem is attached to the cap. By turning the screw-cap the valve is opened or closed, and the oil allowed to flow, or is cut off.

E. An oil-chamber is made in the box and communicates with the bearing surfaces. The reservoir is closed by a screw-plug, and the oil passes gradually to the spindle without special attention.

F. One or more conical openings in the hub, each closed by a spring-lid to which a rod and sponge are attached, extend to the axle. The sponge is charged with oil on opening the lid. This is kept shut by the spring when the wheel is in motion.

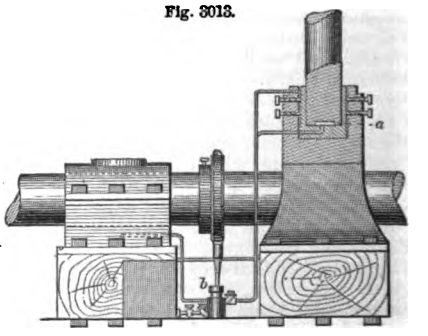
G. An oil-cylinder, having a piston on a screw-rod which works through the cylinder-cap, is inserted in the hub. Turning the head of the rod pushes the piston down, forcing the lubricant upon the axle-spindle. The piston is kept from rotating with the screw-cap by a groove in its edge, into which a feather on the inside of the chamber fits.

H. The depression of the spring-valve allows oil to flow from the chamber to the spindle of the axle.

The patents on lubricators are very numerous. Those referring to *railroad-axles* and *journal-bearings of machinery* are treated separately. Oil cups and cans, which are portable lubricators, are treated of under their proper title, OIL CUPS AND CANS.

The *hydrostatic lubricator* for heavy bearings consists of a chamber *a*, into which oil is forced by a hydrostatic pump *b*. By this means, at every revolution, the shaft is raised from its seat by the pressure of the oil. On the return stroke of the pump, the shaft seats itself on the oil that has been forced under it; the oil returns back to the pump as it flows through the bearing. Unlike other systems of hydrostatic lubrication, this does not seek to keep the shaft in equilibrium; but, on the contrary, it keeps it in constant motion up and down, by the

Fig. 3013.



Hydrostatic Lubricator.

injection of the oil, aiming thus to secure a more perfect lubrication.

Digitized by Google

It is stated that a step in Starr's Flour-Mill, at Vallejo, California, supporting a four-ton shaft making ninety-three revolutions per minute, has been run constantly, day and night, for seven months, with this lubricator, without changing the oil; and the oil, when taken from the reservoir at the end of that time, had not become thickened or discolored in any appreciable degree. See PALIER GLISSANT.

4. (*Ordnance.*) An arrangement for lubricating and cleaning the grooves of rifled guns.

In the English service it consists of a copper wad containing equal parts of tallow and oil, then a felt wad, and then a disk of millboard, all joined together. The copper is placed against the projectile, and when the charge is exploded the oil is ejected and lubricates the bore, while the felt wipes out the piece.

Lu-cer'nal Mi'cro-scope. A microscope in which the object to be examined is illuminated by the light of a lamp.

The object is placed in a sliding tube between the lens and the lamp, which is contained in a box. The image is received on a screen or plate of ground glass.

Lu'ci-fer. Originally, a match tipped with a mixture of chlorate of potash and sulphuret of antimony, which were inflamed by friction upon a piece of emery-paper.

These were superseded by mixtures containing phosphorus. See LIGHTING-DEVICES.

Lu-cim'e-ter. An instrument for measuring the intensity of light. A photometer.

Various photometers have been invented by Huyghens, Rumford, Celsius, Bouguer, Priestley, Ritchie, Arago, and others, which are described under that head. See PHOTOMETER.

Celsius called his device a *lucimeter*, and the name has since been adopted by Deslaurier in his modification of Bouguer's apparatus.

Deslaurier's apparatus is designed for measuring the quality of burning oils by their illuminating power. It consists of two constant-pressure lamps, and its shape is triangular; sheet-iron screen, painted black, and divided into two equal compartments. The latter are turned toward the lamps, while the observer stands on the opposite side, which presents nothing but a flat vertical surface, pierced with a hole bisected by the partition. Each of the two lamps is so placed as to transmit its light to only one compartment, and exactly to the part where the hole is. The hole is covered with a piece of transparent paper, on which the light from the two lamps is contiguously depicted. If their intensity is the same, the observer will perceive no difference. If not the same, one lamp must be moved back until its light is equal to the other in intensity, and the difference in the distance of the two lamps will make the relative quality of the two oils, which, combined with the quantity consumed in a given time, will determine their marketable value. The ratio of value is directly as the squares of the distances.

Luff. (*Nautical.*) The foremost or weather edge or leech of a sail.

To *luff* is to bring the ship's head nearer to the wind.

A *luff-tackle* has a *double* and *single block* and a *fall*, and is used for many purposes.

Luffer-board'ing. Slanting slats placed one aboye another, with intervals, so as to shed the rain, but permit ventilation; or the exit of sound from a belfry, or smoke and steam from a boiling-house.

Luff-tack'le. (*Nautical.*) A purchase composed of a double and a single block. The standing end of the rope is fast to the single block and the *fall* comes from the double.

Luff upon Luff. (*Nautical.*) One luff-tackle applied to the *fall* of another.

Lug. A projecting stud or ear by which an object is grasped or supported, or which affords a bearing or point of attachment; as, —

The lugs on the *parts* of a flask by which they are united. The lugs by which a kettle is supported in a furnace, etc.

Lug'gage-sad'dle. (*Menage.*) A pad on a led horse for carrying baggage.

Lug'gage-van. 1. (*Railway.*) The English term for a baggage-car.

2. (*Vehicle.*) A *fourgon*, or van containing personal baggage, attending on a traveling-carriage.

Lug'ger. (*Vessel.*) A small vessel carrying two or three masts and a lug-sail on each.

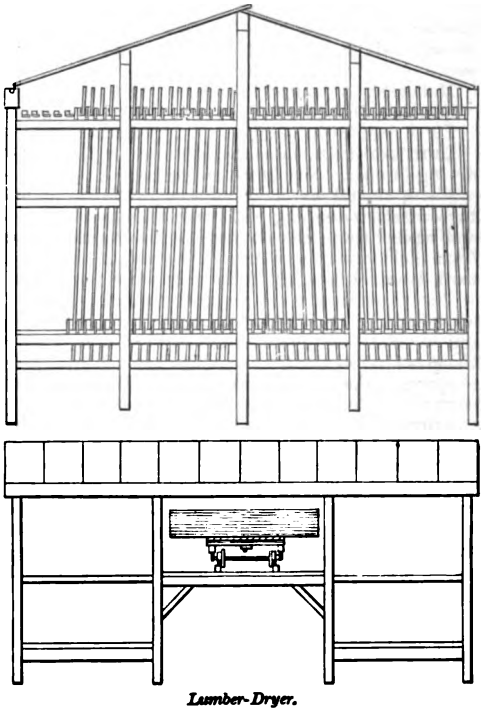
Lug-sail. (*Nautical.*) A four-cornered sail bent to a yard, which is slung at a point ⅓ of its length from the peak.

A vessel thus rigged is a *lugger*.

Lum'ber. Timber sawed into merchantable forms.

Lum'ber-dry'er. A shed or closed chamber in which sawed lumber is subjected to an artificially heated and dried atmosphere. In the example, a series of girts having a ribbed edge on the inside, for the purpose of supporting strips, are arranged

Fig. 3014.



Lumber-Dryer.

within a suitable building, the strips serving to hold boards or lumber on end. The drying-sheds have grated or open floors for sticking lumber standing on end, and are built double with a space between for an elevated railway track and car, the latter having a swivel platform.

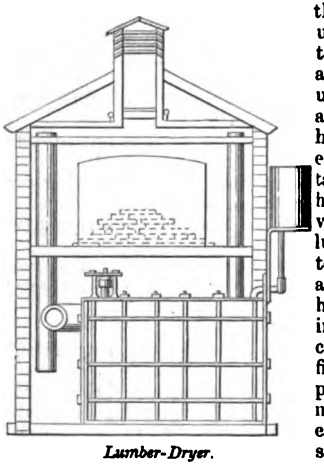
In Fig. 3015, a continuous supply of water is introduced by gravity into the generator. The dry

Digitized by Google

steam is introduced within the kiln, and, after absorbing the moisture of the lumber, is conducted to the escape.

In another apparatus for this purpose, the process consists in subjecting the lumber to the action of a gradually increasing temperature, in an air-tight chamber, until all or nearly all the moisture has been extracted from it; in retaining all the heat and watery vapor about the lumber until a temperature of about 170° Fah. has been attained in said air-tight chamber; and, finally, in compelling the heated moistened air to escape slowly from said chamber while the temperature is reduced therein.

Fig. 3015.



Lumber-Dryer.

Davis and Symington's lumber-dryer, English patent, 1843, acts by means of a heated blast upon lumber or wooden articles placed in a chamber through which the blast is driven. By their process, —

Mahogany is reduced in weight	24.4 per cent.
Pine is reduced in weight .	34.5 per cent.
Fir is reduced in weight . .	12.5 per cent.

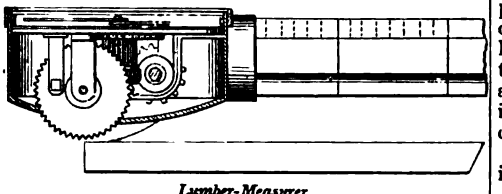
Lum'ber-kiln. A heated chamber for artificially drying lumber. See LUMBER-DRYER.

Plank should never be allowed to remain undisturbed until it seasons; but should all be handled over and repiled from time to time, removing the sticks from their former positions. The planks should be turned over, especially if they have become bilged.

Two to six years are required to season timber, according to its size. It can be seasoned more quickly if it be steamed, but excess in steaming kills the elasticity of the timber. Too rapid kiln-drying evaporates the surface moisture too rapidly, and causes the timber to check.

Lum'ber-meas'ure. One by which the number of superficial feet contained in boards of different lengths can be estimated. Within the case is a disk in a vertical position, which, by being made to pass over the surface of the boards, indicates on a dial their superficial contents. Connected to the shaft of the disk is a sliding shaft, carrying on its end an endless screw, through which the motion of the shaft of the measuring-disk is transmitted to the arbor, carrying the index-heads in such a manner that by simply adjusting the sliding shaft the instrument can be set for boards of different lengths. A sleeve projecting from the bottom of this case and terminating under the center of the disk enables the operator to commence measuring with the edge of the board directly under the center of the disk.

Fig. 3016.



Lumber-Measurer.

Lum'ber-wag'on. A heavy wagon, long coupled, and having standards to the bolsters, for hauling sawed timber.

Lump. 1. A bloom or loop of malleable iron.

2. The nipple-seat on a gun-barrel.

Lu-nette'. A term applied to objects of a half-moon shape.

1. (*Fortification.*) A detached work presenting a salient angle towards the enemy, and having flanks open at the *gorge*.

With the flanks it has the character of a *detached bastion;* without the *flanks*, it would be a *redan;* with the *gorge* closed, it would become a *redoubt*.

2. (*Ordnance.*) A forked iron plate into which the stock of a field-gun carriage is inserted.

3. (*Architecture.*) *a.* An arched aperture in the side of a long vault, and having a less hight than the pitch.

b. A semicircular aperture in a concave ceiling.

c. An opening in the roof of a house.

4. (*Farriery.*) A horseshoe having only the front, curved portion; lacking the branches.

5. The flue connecting the fire-chamber with the pot-chamber of a glass-furnace.

6. (*Harness.*) A blinder for the eyes of an intractable horse.

7. (*Optics.*) *a.* A perifocal spectacle-glass; concavo-convex, its curve approximating the shape of the eye and affording more distinct oblique vision.

b. A flattened watch-crystal or glass, to avoid adding to the thickness of the watch.

The edge of the watch-glass fits within the bezel.

Lurch-line. The line which draws the bird-net over the prey.

Lure. A velvet brush or smoothing-pad used by hat-makers. From *Velure* (Shaks.), velvet. Fr. *Velours;* Old Fr. *Villuse;* from Lat. *Villosus*, hairy. Also called *velour; lever*.

Lus'ter. 1. (*Fabric.*) A lady's dress-goods with a cotton chain, woolen filling, plain or *self* color, and highly finished surface.

2. A sconce or chandelier.

Lus'ter-ing. 1. A polish; as black-luster for stoves, etc.

2. (*Metallurgy.*) The brightening of metal in the crucible at the moment of reaching its point of purity. As in the cupellation of silver, when the last traces of lead pass off. *Brightening; lightening.*

Lus'ter-ware. A stone-ware on whose surface are burnt metallic oxides of brilliant colors. It is made of a mixture of clay, flint, China-stone, and felspar, coated with a peculiar glaze on which is applied, by means of camel-hair brushes, a pigment prepared from metallic oxides, simulating the luster of various metals, etc. Platinum produces a luster like that of polished steel; gold and silver, those of the precious metals. Iron and copper lusters may also be produced. A beautifully iridescent appearance is derived from chloride of silver in combination with other substances.

The luster is brought out by the heat of the oven in the process of baking.

Lus'tring. (*Fabric.*) A shining silk; *lute-string* is a corruption.

Lute. 1. To stop with clay; as the cover of a furnace, or a muffle to resist the passage of fumes, or of a charged retort to prevent the escape of gas around the cover.

Digitized by Google

2. A composition to secure the joints of chemical vessels and tubes, or as a covering to protect them from the fire.

Their compositions are various; e. g. —

1. Linseed-meal and whiting.
2. Lime and bullock's blood.
3. Plaster of paris.
4. Powdered clay and boiled oil.
5. Powdered clay, ground brick, and borax water.
6. Pipe-clay and horse-dung.
7. Vulcanized rubber thimbles.

A lute for the bungs of powder-cases is formed of tallow, 14; beeswax, 6. Melted together and softened by beating before using.

Lutes not exposed to high temperature may be made of *moistened bladder*, *linseed-meal*, and *gum-water*, *white of egg* and *quick-lime*, *glazier's putty* (chalk and linseed-oil), *pipe-clay* and *drying-oil*.

Lutes for high temperatures are made of clay and sand, beaten into a paste and thinned with water. If intended to vitrify, borax or red-lead may be added.

Fat lute is made of finely pulverized pipe-clay and drying linseed-oil. It is used to join parts of apparatus exposed to considerable temperature, and intended to contain corrosive vapors. It is tied on by strips of bladder.

Iron cement is formed of sulphur, 1 : sal-ammonia, 2 ; iron turnings, 80. Calked into the joints.

3. A packing-ring of india-rubber placed between the lid and the lip of a jar, to prevent the access of air to the contents. See FRUIT-JAR.

4. (*Music.*) A musical stringed instrument, played like a guitar, but having a pear-shaped form and a ribbed back. It is derived from the lyre.

The old Egyptian lute is represented in many places in Egypt; one at Thebes has a long neck without frets, three strings, and a fiddle-shaped body.

A lute shown on the signet-ring of Shoofoo, the Suphis of the Greeks (2325 B. C.), has a fretted neck. See the late Dr. Abbott's collection, New York. In Egypt we find the originals of most of the types of musical instruments. See HARP; CASTANET; DRUM, etc.

Fig. 3017.

Ventura's Lute.

The lute consists of four parts: the *table;* the *body*, which has nine or ten sides; the neck, which has as many stops or divisions; and the head or cross, in which the screws for tuning it are inserted. The performer strikes the string with the fingers of the right hand, and regulates the sounds with those of the left.

Simply constructed, it is called the *French* lute.

With two necks, — one for the base notes, — it is called a *theorbo*. If the strings of the *theorbo* are doubled, it is called an *arch-lute*.

Ventura's lute is intended to combine the principles of the *harp*, *lute*, and *guitar*. The performer is enabled to stop the treble strings on a finger-board, which materially increases its compass, and yet retains the fullness of tone of the other strings.

5. A straight-edge employed to strike off the surplus clay from a brick-mold.

Lute'string. (*Fabric.*) A plain, stout silk or silk ribbon : from *lustring*.

Lu'thern. An upright window in the roof. A *dormer*-window.

Lych'no-scope. (*Masonry.*) A narrow window near the ground.

Lye. A solution of an alkali. Used in soap-making; in neutralizing an acid; in cleansing grease from objects, such as thin iron plates in the operation of tinning, etc.

Lyre. A stringed instrument of the harp kind. Its origin is lost in antiquity. It is claimed of course by the Hellenic Greeks, who learned so much from the nations of Egypt, Phœnicia, and Asia Minor, and then slurred the debt in a muddle of mythology. This latter indeed was similarly derived and fearfully garbled. It cannot even be admitted that the Egyptian lyre was but of 3 strings, the other 4 being added by the Greeks to form the *heptachord*. The origin of the lyre is attributed by the Greeks to Hermes. (See HARP.) It was specially the musical instrument of Apollo.

The ancient Egyptian lyre was made in various forms, some of them very ornate. It was sometimes

Fig. 3018.

Egyptian Lyres.

struck with the *plectrum*, and sometimes the strings were played by hand. The strings were of catgut, and numbered from four to eleven in the different figures.

The lyre is represented in the sculptures of Nimroud.

Some of the early Grecian lyres had an arrangement for changing the length of the string. This was done by a sliding bar, which might be moved by the musician during his performance.

The same idea has been introduced in modern lyres or harp-lutes, in which eight strings have, by this means, been made to yield twenty-four distinct tones.

The lyre was, in fact, a small harp, and the hollow resonant portion became, in time, expanded into a chamber over which the strings were stretched in parallelism, forming a *dulcimer*, the immediate parent of the *hammer* group, — *citole*, *clavichord*, *clavicytherium*, *virginal*, *spinet*, *harpsichord*, *piano* (see PIANO). Another, and perhaps earlier, divergence of the instrument with strings in parallelism above a sounding-board is found in a portallo class, — the *monochord*, *cithara*, *guitar*, and a host of other instruments with names less widely known, such as *theorbo*, *pandore*, *mandolin*, etc. These instruments were played by the *fingers* or by a *plectrum*, and from them came out the class of instruments played by the *bow*, of which the *viol* is the head, and the others take their names as relatives, — *violin*, *viola d'amour*, *violoncello*, *bass-viol*. See "Description des Instrumens Harmoniques," by Father Bonanni, Rome, 1776.

M.

Mac-ad'am-iz-ing. A mode of paving roads, introduced by Macadam, the *metal* or surface stone consisting of pieces of granite, whinstone, limestone, or hard freestone, according to the kind of rock which is accessible.

Telford's rule, when two courses were used, was to make the lower one of blocks 7 inches in depth, laid by hand, broad end downward, and chinked with smaller stone.

Over this, 7 inches of smaller stones were laid, no stone to weigh over 6 ounces, and all to pass through a metallic ring 2½ inches in diameter. The stone is broken to uniform sizes, and several machines have been devised for this purpose. See STONE-CRUSHER.

Ellis and Everard's stone-crushing mill has a strong feed-apron, composed of iron links and bars, which, passing around two wheels, delivers fragments of granite to a hopper which feeds them between two chilled-iron crushing-rollers; they then pass between a second pair of rollers which still farther reduce them in size. The rollers are fluted, and may be adjusted to break the stone to any required size. From the rollers they pass to a revolving griddle, which separates those of the proper size. Those which are too large are raised by an elevator to be again passed through the machine. Rolls weighing 10 cwt. each will, it is said, crush 1,800 tons of granite before being worn out; and it is claimed that the work is performed in England at one fifth the cost of doing the same by hand.

The stone-grinding mill of Neal is designed for *pulverizing* stone. See also ORE-MILL.

Mace. 1. (*Weapon.*) A mallet, hammer, or slung-shot used in the Middle Ages to oppose warriors in armor. It had many forms: a simple iron club; a spiked club; a pointed hammer; an iron-spiked ball chained to a handle about 2 feet long. The latter were called *morning stars* by the train-bands of London; a grim pleasantry.

The Assyrian soldiers used "wooden clubs knotted with iron." — HERODOTUS, VII. 63.

The bent maces (*lissan*) are found in the old Egyptian pictures, and are yet common in Africa and elsewhere.

In the times of the Plantagenets the mace was used in battles and tournaments, and was superseded by the pistol in the time of Elizabeth. The mace is still retained among the Turkish cavalry.

2. (*Leather.*) A currier's mallet with a knobbed face, made by the insertion of pins with egg-shaped heads. It is used in leather-dressing to soften and supple the tanned hides, and enable them to absorb the oil, etc. It is analogous to the fulling-hammer.

Mac'er-ate. To wear away by steeping.

To saturate a substance, — fiber for paper, for instance, — so as to distend the fibers.

Mac'er-a'tion. The process of softening and separating the parts by steeping.

A *solution* is the diffusion of the particles of a solid in a liquid without change of its nature.

An *infusion* is a solution obtained by steeping at a moderate temperature.

A *decoction* is a solution obtained by boiling.

A *steep* is a solution obtained by maceration or soaking, as the ooze of bark; or by simply dissolving, as a mineral salt forming a mordant or a fertilizing liquid.

Ma-che'te. The Spanish implement for cutting cane, corn, vines, etc. It is now made in large quantities for the Southern market, and many of the implements are diverted to home use, as corn and cane knives. See CORN-KNIFE.

Mach'i-co-la'tion. (*Architecture and Engineering.*) Apertures between the corbels supporting a projecting parapet. They were much employed in castellated architecture, and were intended for the purpose of allowing missiles to be hurled down on assailants approaching near the walls.

Ma'chi-cou-lis'-gal'ler-y. (*Fortification.*) A projecting gallery with loopholes arranged to obtain a downward fire on an enemy.

Ma-chine'. An instrument of a lower grade than an *engine*, its motor being distinct from the operating part, whereas the *engine* is automatic as to both.

It is also distinct from a *tool*, as it contains within itself its own guide for operation.

Ma-chine'-tool. A machine in which the tool is directed by guides and automatic appliances. Aptly called by Dr. Barnard "a mechanical artisan" with "iron arms." It is a workshop appliance for operating upon materials in the way of shaping and dressing, having devices for dogging the stuff and feeding the tool.

Among tools of this class for working in metal may be enumerated the lathe and machines for planing, slotting, shaping, drilling, punching, and shearing. See METAL-WORKING TOOLS AND MACHINES.

Machine-tools for wood are lathes, saws of various kinds, machines for planing, molding, boring, mortising, dovetailing, rabbeting, tenoning, shaping, etc. For these we are originally indebted to Sir Samuel Bentham and Brunel. See WOOD-WORKING TOOLS.

Ma-chin'ist's Ham'mer. A hammer which has a flat, round face and an edge-peen transversely of the helve. In some branches of the business it has two faces; in others, again, it has one face and a pointed peen for riveting.

Mack'le. (*Printing.*) A blurred impression, causing part of a page to appear double.

Ma-crom'e-ter. An instrument for measuring inaccessible objects by means of two reflectors on a common sextant. — WEBSTER.

Ma'cron. An accent (-) placed over vowels to give the long sound.

Mad-a-pol'lam. (*Fabric.*) A kind of fine, long cloth (cotton) shipped to the East India market.

Mad'der-style. (*Calico-printing.*) A method of calico-printing in which the mordants are applied to the white cloth, and the colors are brought up in the dye-bath. See CALICO-PRINTING.

Made-mast. (*Nautical.*) One composed of several pieces. A *built*-mast.

Mad-is-te'ri-um. (*Surgical.*) A tweezers. An instrument for extracting hairs.

Ma-drier'. *a.* A thick, iron-plated plank, having a cavity to receive the mouth of a *petard*, which is applied to a gate or other obstacle to be blown down.

b. A beam laid in a ditch to support a wall; or in a mine or bomb-proof to support a side or roof.

Mag'a-zine'. 1. (*Fortification.*) A building, vault, or apartment designed for the storage of ammunition, gunpowder, and other explosive substances.

Magazines in field fortifications are constructed in the most sheltered parts of the work, partly underground where practicable, and are lined with timber or with gabions, the ceiling being of timber. The

Digitized by Google

whole is covered with a sufficient thickness of earth to render the structure bomb-proof.

Permanent magazines are usually constructed of brick, and should be surrounded by an earthen mound, so that in case of explosion the tendency of the explosive force may be upward.

As little iron as possible should be employed in the construction, and all iron nails, etc. should be sunk below the surface of the wood and their heads puttied over. The windows have exterior metallic shutters and interior shutters of wire-gauze; ventilators, closed by sliding metallic shutters, are also generally arranged around the lower part of the sides of the building. Powder is stored in barrels, three or four tiers high, with skids between each tier, or sometimes racks are arranged to receive the barrels. Alleys of sufficient width are left between the several piles to obtain ready access to each barrel. Fixed ammunition and small-arm cartridges are piled in a similar way, but these, when practicable, should not be placed in the same magazine with gunpowder.

2. (*Nautical.*) On shipboard the magazine is an apartment placed sufficiently below the water-line to be safe, under ordinary contingencies, from the enemy's shot. It is lined with sheet-copper, and has tiers of shelves on three sides and in the middle for the reception of the copper canisters, in which the cartridges for the heavy guns are contained. It is illuminated by a peculiarly constructed lamp and reflector placed at one end of and just outside the magazine, and carefully isolated therefrom. In action, the cartridges, when taken from the ammunition-boxes, are passed through a scuttle by a man in the magazine to another on the deck above, who in turn delivers them through a canvas screen having an opening covered by a flap, to another on the other side, who hands them to the runner-boys, who pass them through scuttles to others on the deck or decks above, until they reach the powder-boys, who deliver them to the loaders stationed at the guns.

Large vessels have two magazines, one forward and the other aft.

3. (*Stove.*) A chamber in a stove or furnace containing a supply of fuel which falls or is fed into the combustion-chamber as the fire burns away that previously introduced.

The first magazine-chamber for fuel known to the writer is the Athanor of the alchemists of the Middle Ages. This was the original *base-burning* furnace, and was adopted to keep up a continuous supply to the fire, which it was hoped would eventually transmute the baser metals into gold. See ATHANOR.

Delasme's furnace, 1685, is not exactly a magazine, but is a downward-draft furnace. See SMOKE-CONSUMING FURNACE.

Watt's base-burner furnace had a magazine (English patent of 1785). The fire is fed from a reservoir above, and the resulting volatile products pass through the fire to the chimney.

Cutler's magazine-grate was patented in England in 1815. The bottom plate of the chamber was movable, and by means of a wheel and axle the fuel contained in the chamber was raised so as to bring a new portion of fuel into the fire. The object is a full supply for a day, and a means of introducing below so as to burn the smoke.

Arnott's improvement, which he termed a smokeless fireplace, is somewhat similar.

Deakin's patent, 1816, had the magazine at the back of the fire, and the fuel was drawn forward horizontally by means of a screw.

Alkin's English patent, 1825, resembled Deakin's.

Rawe's magazine, 1854, is a fuel-pipe connecting the bottom of the grate with a side reservoir of fuel. The poker is the lever for introducing a fresh supply.

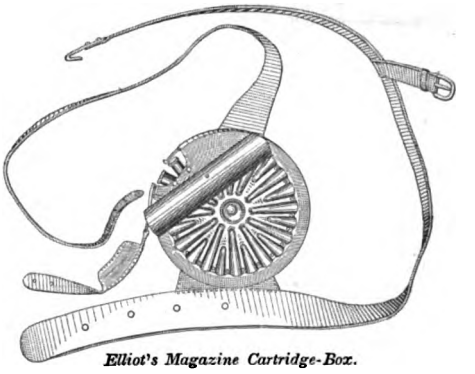
Leighton, in 1856, surrounded the sides and back of the chamber with a fuel-reservoir, from which the fuel was withdrawn by the poker. See MAGAZINE-STOVE.

4. (*Fire-arm.*) A chamber in a gun containing a succession of cartridges, which are fed one by one automatically, and loaded at the breech of the gun. See MAGAZINE FIRE-ARM.

Mag'a-zine' Car'tridge-box. A cartridge receiver attached to a gun, or to the person near the gun, to facilitate loading.

"Elliot's cartridge-box consists of two metallic plates mounted side by side on a common pivot, by which they are secured to a skeleton metallic frame covered with leather. They are fluted radially for the reception of 24 cartridges. These flutings are so arranged that the heads of the cartridges may lie in an almost continuous row, while the points overlap each other in such a manner that the cartridges

Fig. 8019



Elliot's Magazine Cartridge-Box.

are mutually supported by the ends of their cases, the weight being thus taken off the point of the ball, and removing its liability to be driven into the cartridge by the shaking of transportation.

"The box when used is to be worn on the left breast. When charged it is rotated for firing by bringing each cartridge in succession to an open notch in the periphery of the frame." — *U. S. Ordnance Memoranda*, No. 15, p. 339.

Merrill's box is a slot in the top, back of the *small* of the stock, from which the cartridges are taken by hand and fed to the chamber.

Hagner's magazine is a box large enough for three cartridges, open at one end, and situated under the barrel, forward of the trigger-guard.

Benton's, Hare's, and Metcalfe's magazine-boxes are detachable blocks containing each a number of cartridges. The blocks fit in the cartridge-box, and when in use are attached to the side of a rifle, near the breech-block, by dovetail or pin fastening.

Mag'a-zine' Fire-arm. One containing a supply of cartridges, which are automatically fed to the chamber at the rear end of the barrel. There are several types.

1. Those in which the magazine is a tube below the barrel, as in the Winchester, the Ward-Burton, etc.

2. Those in which the magazine is in the stock, as in the Spencer, Meigs, and others.

3. Those in which the magazine is a separate piece attachable to the gun when required, as in the Elliot carbine, the Gatling battery-gun, etc. See BATTERY-GUN.

The Marquis of Worcester (d. 1667), in his "Cen-

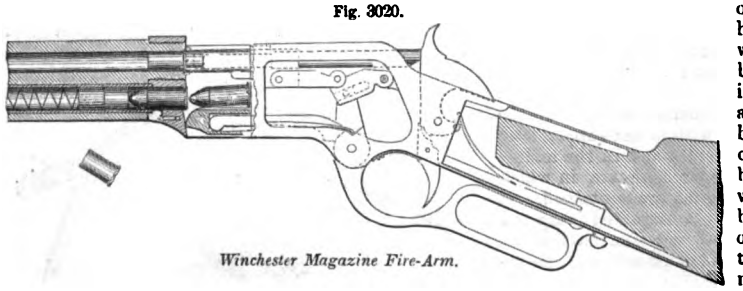
Digitized by Google

tury of Inventions," refers to an "often-discharging pistol," but does not describe it. In 1575, several of such arms were stored in the Tower of London. Porta, in his "Natural Magick," 1658, speaks of a great brass gun, or hand-gun, which may discharge ten or more bullets without intermission. The idea is to load with powder and shot alternately, until the barrel is full; an intervening "dark powder" gives an interval between the firing of the separate charges, so as to avoid the simultaneous explosion and the results which would very certainly follow.

Most of the ancient repeating-guns were many-chambered revolvers, and not what we term magazine-guns. See REVOLVER.

The Henry or "Winchester" rifle will fire sixteen shots without reloading, and the gun is cocked by the same movement of the guard that opens and closes the breech; the exploded cartridge being withdrawn and a fresh one supplied at the same time and by the same movements. The copper cartridges, fifteen in number, are placed in a tube extending the entire length of the barrel on its under side, from which they are fed into the gun by the operation of the lever-guard, a spiral spring forcing back the cartridges as fast as they are used up. The piece has been fired fifteen times in less than ten seconds. 187 shots were fired in 3 minutes and 36 seconds, not including the time required to replenish the magazine; and, including the time thus employed, 120 loads were loaded and fired in 5¾ minutes, — 1,040 shots being fired without cleaning or repairing the gun. See *Y Y'*, Plate XVIII., FIRE-ARM.

Fig. 3020.

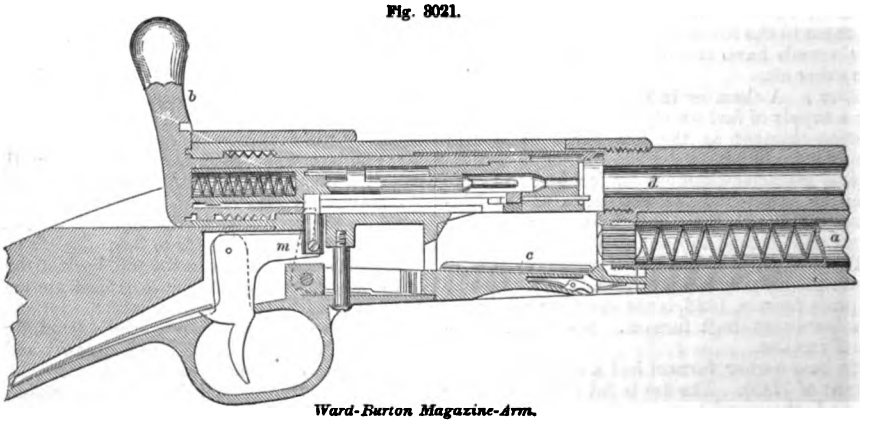


Winchester Magazine Fire-Arm.

Fig. 3020 shows a longitudinal section of the breech and working parts of the magazine, with a cartridge on the carrier ready to be fed to the firing-chamber.

The Ward-Burton arm is on the bolt system. A supply of cartridges is carried in a tube *a* beneath the barrel. These are fed backward by a spiral spring. The gun is opened by raising the handle *b* of the bolt and withdrawing it. As the bolt is fully drawn back, it strikes the upright arm of the carrier, shown by dotted lines (at *m*), on the tray *c* formed by the lower arm of which a cartridge has been fed by the action of the spiral spring in the magazine-tube. The motion of the bolt brings up this tray, so that, when pushing forward the bolt again to close the piece, the cartridge may be driven into the chamber *d*, where it is fired by the action on a heavy needle or pin of a spiral spring contained in the bolt and compressed in the act of closing, during which, also, the carrier is forced down to receive a fresh cartridge from the magazine.

Fig. 3021.



Ward-Burton Magazine-Arm.

Projecting from the face of the bolt is seen the point of a spring hook, serving to withdraw the empty shells from the chamber, and also the end of the ejector-pin, which strikes them from below when withdrawn, and throws them clear of the gun. Near the head of the bolt is seen part of the sectional screw, which engages with a corresponding section within the gun when the piece is closed, and the handle turned down into place, and so supports the bolt against the force of the discharge. The magazine holds eight shots, which may be fired in about nine seconds; their issue may be cut off by a sliding piece; the arm may then be used as a single loader, (as shown in Plate XVII., opposite page 852), holding the magazine in reserve.

The Swiss magazine-rifle (shown on Plate XVIII., opposite page 853) has the bolt feature of the Ward-Burton, and the cartridge-loader of the Henry, so well known as the "Winchester."

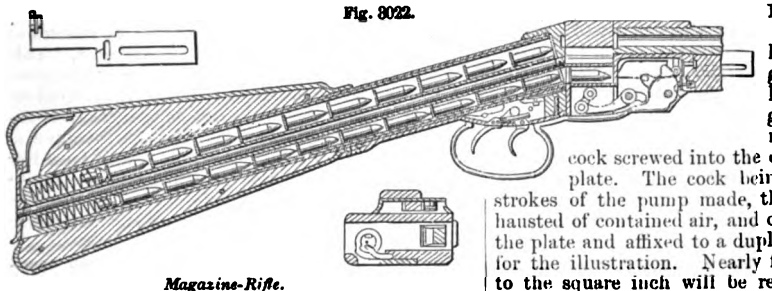
The Spencer has a tube containing seven copper cartridges placed lengthwise in the stock, from whence they are forced, one at a time, into the barrel, by merely moving the lever-guard forward and back, — the shell of the exploded cartridge being removed by the same operation. The gun is then cocked and fired in the usual manner. This gun was more extensively introduced into the army, during the late civil war, than any other of its class,

Digitized by Google

and is, therefore, very generally known. It is shown at *F*, Plate XVI.

The Cullen magazine-gun (Fig. 3022) has a revolving cartridge-carrier in the stock, which contains four sets of cartridges, ten in each set or column. As one column is exhausted another comes in place, so that forty shots may be fired without reloading.

Fig. 3022.



Magazine-Rifle.

The operating mechanism is connected to the trigger-guard, which works as in the Spencer.

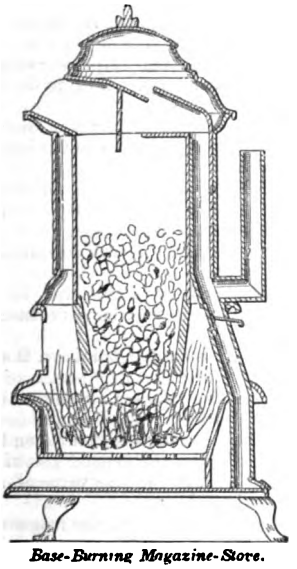
The Meigs magazine-gun, made at Lowell, Mass., contains five columns of ten each, or fifty cartridges, which were fired before the Austrian Military Committee in 16 seconds, and replaced by another magazine in a few seconds. The breech-block rises and falls by a backward and forward sliding reciprocation of the trigger-guard. When one line of cartridges is expended, the magazine is rotated on its axis by a spring bringing another line of cartridges in line with the feeding arrangement.

A number of magazine-guns carry cartridges in the stock, linked together like sausages, which are cut apart as they are used. See classification list under FIRE-ARM, pp. 854 – 862.

Mag'a-zine'-stove. One in which is a fuel-chamber which supplies coal to the fire as that in the grate burns away.

The example is a base-burning stove, having a

Fig. 3023.



Base-Burning Magazine-Stove.

fuel-magazine suspended free from the grate, and having an unobstructed free space around and below it, an illuminated casing surrounding it. See BASE-BURNING STOVE.

Mag'de-burg Hem'i-spheres. Hemispheres of brass whose edges are carefully ground together to make an air-tight joint, and designed to illustrate the pressure of the atmosphere. The experiment originated with the worthy Otto Güericke, burgomaster of Magdeburg, about 1654.

The edges of the hemispheres, being greased with oil or tallow, are brought together, the foot removed, and the stop-cock screwed into the center of the air-pump plate. The cock being opened and a few strokes of the pump made, the sphere is thus exhausted of contained air, and on being removed from the plate and affixed to a duplicate handle is ready for the illustration. Nearly fifteen pounds of force to the square inch will be required to draw them asunder. To separate them readily, it is only necessary to open the stop-cock and re-admit air.

Fig 3024.

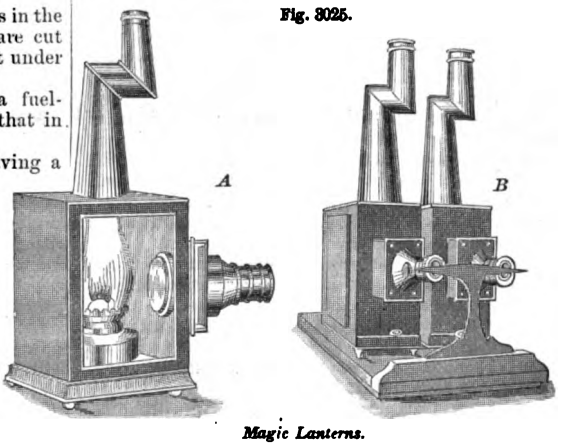
Magdeburg Hemispheres.

Mag'ic Lan'tern. A dioptric instrument by which the images of small figures painted in transparent varnish are exhibited, considerably magnified, upon a wall or screen.

Its invention has been attributed to Roger Bacon about the year 1261, but it was first generally made known by Baptista Porta in his "Natural Magick," and by Kircher, 1669 – 70, who described it in his "Ars magna Lucis et Umbræ."

"Comes Mr. Reeves bringing me a lanthorn with

Fig. 3025.



Magic Lanterns.

pictures in glass to make strange things appear on a wall, very pretty." -- PEPYS'S *Diary*, 1666.

As at present constructed, the instrument *A* consists of a case having a projecting tube in front, in which are two lenses, the inner for illumination and the outer for magnifying. A strong light is placed in the center of the box, and behind it a concave mirror. A widened space between the two lenses in the tube permits the insertion of the slips of glass on which the objects are painted. These are highly illuminated by the mirror and lens; and the magnifying-lens, which is adjustable to a proper focus by sliding it back and forth in the tube, throws a magnified image of the object on the screen placed to receive it. The magnitude of the image depends on the distance of the image from the screen, being greater the farther apart they are separated; this dis-

Digitized by Google

tance must not, however, be too great, or the image will be indistinct.

When the screen is transparent the exhibitor may be behind it, the picture being exhibited by transmitted light. With a white opaque screen, or a whitewashed wall, the camera is placed in a suitable position among the audience, and the picture, being thrown upon the screen, is viewed by reflected light.

The oxy-calcium light, in which a jet of oxygen gas passing through a spirit-flame is thrown on a cylinder of lime, or the electric light, are used in the magic-lantern, affording an illuminating power vastly greater than that of the ordinary oil lamp.

Fig. *A* represents a single lantern, and *B* a double lantern, the latter arranged for exhibiting dissolving-views. The lanterns are placed side by side, so that the sliders may be readily slid from one to the other. Their foci and the screen being properly adjusted, a picture is placed in each; in front of both tubes is a slider, by which the image of either is gradually shut off from the screen, so that one image will appear to dissolve into the other.

Mag'is-ter'y. A fine substance deposited by precipitation.

Mag'is-tral. 1. (*Metallurgy.*) Made from copper pyrites (or raw magistral), which is found in many parts of Mexico. These ores, according to Napier, contain from 7.47 to 13.75 per cent of copper. It is reduced to powder by dry stamping and grinding. It is used especially in the *patio* process of amalgamation. Some authorities state that the copper pyrites are *roasted* and ground, but this would seem to detract from their activity, which is due to the action of their sulphuric acid upon the salt, liberating muriatic acid. So say Sonneschmid and Phillips. See AMALGAMATOR, p. 76.

2. (*Fortification.*) The line where the scarp, if prolonged, would intersect the top of the coping or cordon. — MAHAN.

The guiding line which defines the first figure of the works of a fortification.

Mag-ne'si-an Lime'stone. A mineral which crystallizes in the rhombohedral system.

Mag-ne'si-um. Equivalent, 12; symbol, Mg.; specific gravity, 1.743. A malleable metal the color of silver.

As a silicate or carbonate, it enters into the composition of many rocks and soils; steatite, serpentine, talc, meerschaum, etc.

The oxide, sulphate (epsom-salts), and carbonate are used in medicine.

It is also used in lamps. See MAGNESIUM-LAMP.

Mag-ne'si-um-lamp. One in which burning magnesium is employed for purposes of illumination.

This metal, in a state of combustion, emits a light which is unendurable to the naked eye, but at the same time gives forth a cloud of its oxide which eventually fills the apartment in which it is burned.

Various attempts have been made to obviate this difficulty, and it is found that by alloying with zinc the quantity of light is undiminished while the fumes are more readily removed. An alloy with thallium has also been successfully tried.

As the flame possesses, though in a much inferior degree, the actinic power of the sun's rays, it may be employed in photography.

Broad thin strips, presenting a proportionately greater surface to the oxygen of the atmosphere than those of equal weight which are narrower and thicker, burn more steadily and surely, and are preferable for giving light.

A long strip of this kind is coiled about a drum and fed by clock-work into the flame of a small alcohol lamp. There may, of course, be various modifications of the mechanism employed.

In one form of magnesium-lamp the metal is employed in a pulverized state, and may be used either alone, mixed with sand, or with a material as nitrate of strontia, to give color to the flame. It is placed in a funnel-shaped reservoir, from the lower part of which proceeds a long, narrow tube, at the lower extremity of which is a small spirit-lamp. This serves to ignite and maintain the flame of the powdered magnesium, the flow of which is regulated by means of a small finger-tap, so as to increase or diminish the light as required. The spirit-lamp also prevents the end of the tube from being fouled or stopped up by the oxide, which would otherwise form within and around it.

Such lamps may be made of convenient size for portability.

The light emitted by a magnesium wire one thousandth of an inch in diameter is equal to that of seventy-four stearine candles of five to the pound; three feet of it are burned per minute, or a quarter of an ounce per hour, the cost of which, at the present price, would be about 60 cents. Seventy-four stearine candles would, however, in the same time consume 2 pounds of stearine, which would cost 50 cents; 40.4 cubic feet of coal-gas of twelve candles power would be required to produce the same effect, and would cost about 5 cents. The dearness of magnesium arises from the high price of sodium required in obtaining it. Magnesium gives off $\frac{1}{765}$ of the heat obtained by combustion of gas of equivalent lucid effect. Gas and candles vitiate the air by the production of watery vapor and carbonic acid: magnesium is free from this objection, but it has an inconvenience of its own; a large quantity of calcined magnesia is thrown off as a fine powder, as stated above.

Mag'net. The attractive power of the loadstone or magnet was early known, and is referred to by Homer, Aristotle, and Pliny.

Says Pliny: "The magnet-stone is found in Cantabria." We read that the architect Dinochares was employed by Ptolemy to roof a temple at Alexandria with "magnet-stone," by means of which an iron image of his sister Arsinoe might remain perpetually suspended. Both the architect and the king died before the completion of the work.

This was probably the original of the popular fable of the suspension of the coffin of Mahomet at Medina between two magnets.

The name is derived by the imaginative Greeks from one Magnes, a shepherd on Mt. Ida, whose iron crook being casually laid against a block of magnetic iron became attached thereto, and directed attention to the mysterious attraction.

Thales, B. C. 640, discoursed on amber and the magnet, and supposed them to be living because they had a moving force.

"From Eastern Asia has been handed down the knowledge of the directive force and declination of a freely suspended magnetic bar; from Phœnicia and Egypt the knowledge of chemical preparations (as glass, animal and vegetable coloring substances, and metallic oxides); and from India the general use of *position* in determining the greater or less value of a few numerical signs." — HUMBOLDT.

Ætius, A. D. 500, refers to the use of the magnet for the cure of disease. He says: "We are assured that those who are troubled with gout in their hands or their feet, or with convulsions, find a relief when they hold a magnet in their hand."

Digitized by Google

Several eminent physicians of the fifteenth century affirmed its virtues as a cure for toothache, and a little later we read of magnetic toothpicks for the same purpose.

The deviation of the compass was known before Columbus, but it was assumed to be uniform. The first voyage of the great discoverer was nearly brought to an abrupt conclusion by the discovery of this error. See MARINER'S COMPASS.

The *dip* of the magnet was discovered by Robert Norman, 1576. See MAGNETOMETER.

The magnet worn by Sir Isaac Newton in his ring weighed only 3 grains, yet was able to take up 746 grains, or nearly 250 times its own weight.

Artificial magnets were made by Dr. G. Knight in 1746.

A natural magnet is the loadstone, which possesses polarity like a magnetic needle.

A magnetized needle is a piece of steel or iron to which polarity has been imparted by contact with a loadstone, or by other means. A manuscript of A. D. 1206, in the Royal Library of Paris, states that a black stone, called *marinière*, was rubbed by sailors upon a needle, which was then placed on a straw set afloat in a basin of water, when the point would indicate the north. See MARINER'S COMPASS.

A nicely balanced piece of steel, suspended by its middle by a piece of untwisted silk, will, when magnetized, turn in one direction and rest there.

Its deviation from the true meridian is its *variation* or *declination*; its deviation from a horizontal position is its *dip* or *inclination*.

Polarity may be conferred upon a bar of steel by different means: —

1. A steel bar held in the natural direction of a needle, and struck several blows with a hammer, will become magnetized.

This occurs on a large scale in building iron ships. It is found that the constant hammering, in closing the seams and swaging the rivets, confers polarity upon the vessel, and the effect is much dependent upon the magnetic bearing of the ship while on the stocks. See MARINER'S COMPASS.

2. If the end of a steel bar be placed in contact with one of the poles of a magnet, it will become permanently magnetic by induction. A better plan is to place the bar in a line between the two opposite poles of two magnets of great intensity. — BRANDE.

3. Take a smooth bar of iron, place the middle of it on the north pole of a magnet, and draw it to the end, repeating the stroke always from the middle to the end, that is, rubbing the same way every time. Then place the middle of the bar on the south pole of the magnet and rub it to the opposite end of the bar, repeating as before.

Or take two magnets and lay them horizontally upon the bar, having their north and south poles in contact over its midlength. Then slide each toward the end of the bar. Repeat.

4. Place a horseshoe-magnet in the middle of a needle to be magnetized, with the poles turned in a direction the reverse of the poles intended to be given to the needle; then move the magnet backward and forward over and along the surface of the needle, taking care to pass over each half of it an equal number of times, and repeating the same operation on the other side: the needle is speedily and permanently rendered magnetic. — BRANDE.

We are indebted to Faraday for the comprehensive classification of all substances into *magnetics* and *diamagnetics*. A compass-needle made out of a diamagnetic would point east and west, where an ordinary compass-needle would point north and south.

In telegraphy the magnets are known by their duty or their places in the circuit, as the *sounding*, *relay*, *receiving* magnets, etc. See ELECTRICAL APPARATUS.

Mag-net'ic Bat'ter-y. A combination of bar magnets acting together.

Mag-net'ic Com'pen-sa'tor. An apparatus of iron plates, invented by Barlow, and placed near the binnacle for neutralizing the effect of ship's guns and other iron in deranging the bearings of the compass. It is superseded by the apparatus of Professor Airy, which consists of two magnets placed at right angles to each other below the compass, and a box of small iron chain. These are placed by experiment. See MARINER'S COMPASS.

Mag-net'ic Guard. A respirator with a gauze of magnetic iron to arrest particles of steel dust when dry-grinding cutlery. Invented by Abraham of Sheffield, England.

Mag-net'ic Nee'dle. A slender, poised bar or plate of magnetized steel.

The forms of magnetic needles are varied, according to fancy. Some have their greatest breadth in a vertical, others in a horizontal, direction. In surveying-instruments, $\frac{1}{10}$ of an inch broad and $\frac{1}{50}$ thick is a fair proportion; length from 4 to 7 inches, usually from $5\frac{1}{2}$ to 6. The needle is suspended by a metallic or jeweled center upon a hardened steel pivot. The test of delicacy is the number of horizontal vibrations which it will make before coming to rest. See MARINER'S COMPASS; MAGNETOMETER.

Mag-net'ic Tel'e-graph. See MAGNETO-ELECTRIC TELEGRAPH.

Mag'net-o-e-lec'tric Ma-chine'. One in which an electric current is generated by the revolution of one or more soft iron cores surrounded by coils of wire, about the poles of a magnet or magnets; or an armature (*keeper*) may rotate before the poles of stationary coils.

The first notice we find of exciting electric action by the revolution of a magnet is in a manuscript work, written in the year 1242, by an Arabian named Bailak, a native of Kibdjak. The work is called "The Merchants' Guide in the Purchase of Stones." He states: —

"Among the properties of the magnet, it is to be noticed that the captains who sail in the Syrian waters, when the night is dark, take a vessel of water, upon which they place a needle buried in the pith of a reed, and which thus floats upon the water. Then they take a loadstone as big as the palm of the hand, or even smaller. They hold it near the surface of the water, giving it a rotary motion, until the needle turns upon the water; they then withdraw the stone suddenly, when the needle, with its two ends, points south and north."

Faraday's discovery of magneto-electricity was announced in 1831. In 1833, Saxton constructed a machine of this kind, employing a commutator to cause the current to flow continuously in the same direction. The coil of wire of the armature was wound transversely to its soft iron core.

In 1857, Siemens constructed a magneto-electric machine, in which an elongated cylindrical armature, wound with insulated wire in the direction of its length, was made to revolve between the poles of a number of parallel horseshoe magnets. By this means much more powerful currents were obtained.

In 1866, Mr. Wilde of Manchester, England, conceived the idea of passing the current developed by an apparatus of this kind through the insulated wire of an electro-magnet of larger size. He found that the force of the magnetism thus excited was far greater than that of the series of steel magnets employed to generate the magneto-electric current. In

Digitized by Google

one case where these would support a weight of but 40 pounds, the electro-magnet which they excited sustained 1,088 pounds.

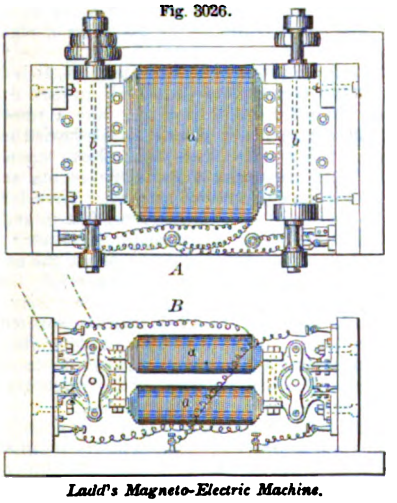
He next constructed a machine of much greater power, consisting of a series of permanent steel magnets, fifteen inches long, each weighing three pounds, and capable of sustaining a weight of 20 pounds. Their common armature is 16 or 17 inches long and 2½ inches in diameter. It is wound with 50 feet of copper wire of $\frac{1}{10}$ inch diameter. By means of a pulley it is driven at the rate of 2,500 revolutions per minute, causing 5,000 changes of polarity in that time. The currents thus generated are turned in a common direction by means of a commutator, and sent through the wires of a large electro-magnet, which forms the base of the apparatus.

This electro-magnet is formed of two soft iron plates, 3 feet long, over 2 feet wide, and 1 inch thick, placed parallel to each other and separated at one end by a bundle of iron plates more than a foot thick, the whole secured together by bolts. At the other end is the armature, a cylinder of 7 inches diameter, deeply grooved in the direction of its length, and wound with copper wire nearly ¼ inch in diameter. More recently, Mr. Wilde has substituted insulated copper ribbon for the wire.

The armature turns in a hollow iron cylinder lined with brass, and is driven at the rate of 1,700 revolutions per minute. This machine maintains in full incandescence carbon points nearly an inch in diameter. It weighs 1½ tons, and requires a three-horse-power engine to drive it. The currents induced by this apparatus have been passed through a second electro-magnet of still larger size, producing still more powerful effects.

Subsequently, Siemens and Wheatstone discovered means of greatly intensifying by means of its own action a very small amount of magnetism, by the rotation of a secondary coil with cores of soft iron around the poles of a magnet of very feeble power.

Fig. 3026.



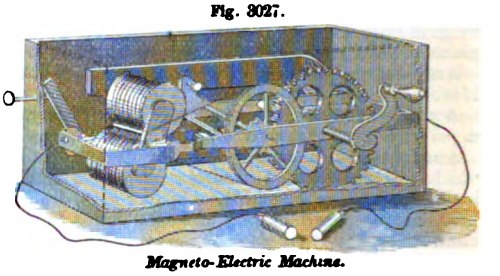
Ladd's Magneto-Electric Machine.

The induced current will also be feeble, but by being sent around the electro-magnet which produced it, its magnetism will be intensified, so that it will generate a stronger current. This again is passed through the secondary electro-magnet, and so on, the current alternately passing from the coil of the primary to those of the secondary magnet until it is intensified to a very high degree.

Ladd's machine, of which a plan *A* and an elevation *B* are shown in Fig. 3026, comprises two magnetic iron plates *a a*, surrounded by coils of wire, and having an armature *b b* at each end. The wires of one ar nature are connected with a commutator, and the extremities of the wire which envelops the plates are connected with tangents resting upon the commutator.

The currents generated by the revolution of the armature pass by the commutator into the wire en-

Fig. 3027.



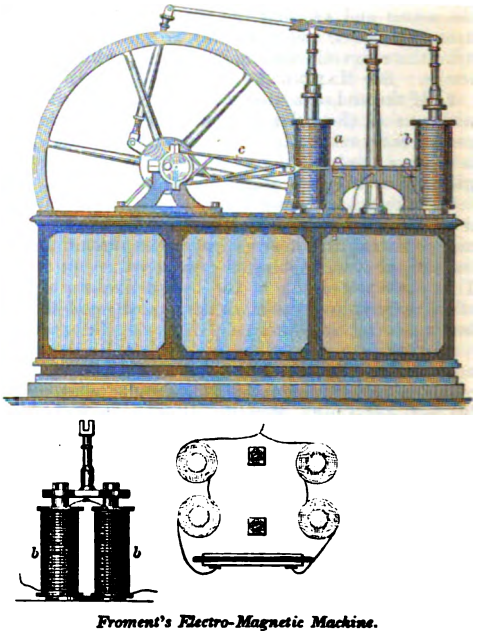
Magneto-Electric Machine.

veloping the plates, thus tending to reinforce their magnetism; and the current, feeble at first, quickly acquires strength with the rapid rotation of the armature.

If the other armature be now set in rapid motion, and the extremities of its helix connected with the conductors of an electric lamp, a light of intense brilliancy is produced; or platinum wire, $\frac{1}{10}$ inch in diameter, may be instantly ignited.

Fig. 3027 is a machine for medical purposes. The armature of the two magnets is rotated by a cord or

Fig. 3028.



Froment's Electro-Magnetic Machine.

belt on a small pulley, driven by a larger one which is set in motion by a hand-crank and gearing. Two conducting-wires with insulators convey the current to the parts under treatment.

Digitized by Google

Fig. 3028 represents an electro-magnetic engine, invented by M. Froment and employed by him for actuating his dividing-engine.

Four hollow cylinders *a a*, *b b*, encircled by coils of insulated wire, surround an equal number of reciprocating cores connected to the beam of the engine. Each pair of cores is connected by a transverse bar. The cylinders *b b* have their lower halves occupied by two other iron cylinders also connected together. The opposite poles of the upper and lower cylinders, which form two distinct magnets, are in reverse directions, so as to mutually attract each other. Under the influence of a voltaic battery, by suitable connecting wires, the core of the upper magnet is brought in contact with that of the lower, depressing that end of the beam, and at the same time, through the medium of an eccentric on the fly-wheel and rod *c*, actuating an ivory slider with a metallic slip on one of its surfaces, breaking the circuit thus formed, and bringing the slip in contact with a wire communicating with the electro-magnets *a a*, closing the circuit on that side and depressing the other end of the beam, which movement again opens the circuit on that side, and brings the metallic slip in contact with the circuit-wire attached to *b b*, which is again brought into action, depressing its end of the beam. A continuous reciprocating motion is thus kept up, rotating the fly-wheel through an ordinary crank and connecting-rod.

Mag'net-o-e-lec'tric Tel'e-graph. An apparatus for transmitting messages by means of an electric current excited by the r tation of one magnet about the poles of another, instead of a current excited by the voltaic action of a battery.

Professor Wheatstone's apparatus for private use in offices and manufactories is of this character, requiring no battery or chemicals.

By one of his instruments the message is printed on tin-foil in Roman characters, and dropped into a locked box till the arrival of the owner.

By another instrument the needle points to the letter itself on a dial.

Mag-net'o-graph. An instrument which registers automatically the condition and changes of terrestrial magnetism.

That in use in the Greenwich Observatory is the invention of Mr. Brooke. Two of the magnets are suspended by untwisted silk for observation in *variation*, and one upon knife-edges on agate plates for observation of the dip ; and the duty of visiting the magnets and observing their variations is attended to every two hours.

Mr. Brooke introduced an automatic plan, which is as follows : —

Around the magnets are cases of zinc which exclude the light. Inside each case is a lamp which casts a beam of light upon a mirror soldered to the magnet. This ray directed to a sheet of sensitive photographic paper records the motion of the magnet, the sheet being moved by clock-work.

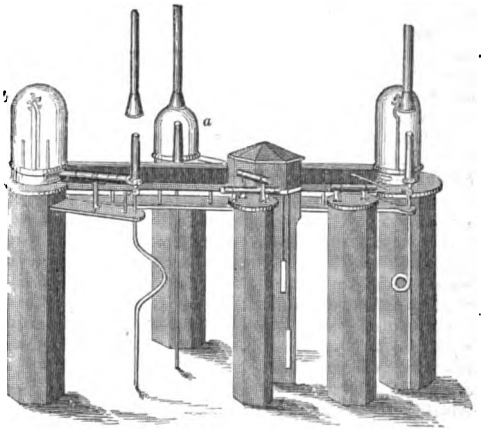
Once in twenty-four hours an assistant darkens the room, and then, with a lantern giving only a yellow ray, he removes the photographic paper, fixes the picture, and places another sheet in the case.

Fig. 3029 is a view inside of the magnetic observatory of Stonyhurst College, England, and will give an idea of the disposition of the instruments.

The instruments record the oscillations of three magnets suspended under the glass shades, and thus show completely all the changes, both as to direction and intensity, in the earth's magnetism. The magnet which is to the right in the sketch is suspended by a silk thread in the magnetic meridian, and, by the aid of a mirror attached to it, describes on a cylinder, which is put in motion by the clock on the center pier, all the variations in the magnetic declination. The other two magnets give the two components of the total magnetic force of the earth. The one *a* which records the variations of the vertical component rests on two agate edges, while the horizontal component magnet *b* is suspended by a double steel thread, and is held nearly at right angles to the magnetic meridian by the torsion of the thread.

Under the clock-box are the three cylinders covered with sensitive paper. To each magnet is attached a semicircular mirror, which sends the rays from a jet of gas to one of the cylinders in the clock-box, and thus describes, by a curved line, all the oscillations of the magnet. A second semicircular mirror is fastened to the pier on which the instrument stands, and, describing always a straight line on the cylinder which is opposite to it, gives the zero line for the curve.

Fig. 3029.



Magnetographs (Stonyhurst College, England).

Mag'net-om'e-ter. An instrument for measuring any of the magnetic elements, as the *dip*, *inclination*, and *intensity*. — WEBSTER.

A magnetized needle, isolated from all disturbing influences and suspended by untwisted silk, is used to detect the declination, and the delicate mode of adjustment permits any variation in this element to be observed.

For observing the *dip* or *inclination* the magnetized needle is balanced by knife-edges upon agate planes, so as to vibrate like the beam of a pair of scales.

The buildings appropriated to this purpose at the Greenwich Observatory, England, are built in the form of a cross, of materials from which iron is rigidly excluded. In two arms of the cross are magnetized needles suspended by silk, for observations in declination or *variation ;* and in another arm of the cross is a balanced needle, for observations in inclination or *dip*. The arrangements were under the control of Mr. Glaisher, and the observations were originally made by himself and two assistants, until Mr. Brooke introduced his adaptation of photography to the purpose of recording observations. By means of mirrors attached to the arms of the magnets, reflected light is cast upon highly sensitized photographic paper wound round cylinders moved by clock-work, and the slightest variation of

Digitized by Google

the magnets is registered with the greatest accuracy. See MAGNETOGRAPH.

We shall have occasion to show that the mariner's compass originated in China, and came thence through India and Arabia to Europe. The Chinese annals show that it was used by them nearly 3,000 years ago, — first on land, then on water. Humboldt remarks the singular fact. It was used at sea by the Chinese as early as the era of Alexander the Great. No mention is made by his historians of the wonderful instrument, although they have not forgotten to note that he was met by a people with storms of lightning and thunderbolts; another Chinese invention, — gunpowder.

The original mode of suspending the needle was by flotation, several devices being used for this purpose, such as burying it in pith, laying it on a couple of floating sticks, etc. These plans gave the needle freedom of motion in a horizontal plane and sufficed apparently for many ages. The same plan was adopted in Europe for several centuries. See p. 1371.

About the twelfth century of our era, or earlier, the Chinese introduced the mode of suspending the needle by a silken string. This delicate adjustment allowed other elements of terrestrial magnetism to be observed; and during the thirteenth century the Chinese philosopher, Keon-tsoung-chi, observed the variation of the needle from the cardinal points to the extent of 2° to 2° 30′. The French savans in Pekin, a few years since, determined it to be about the same. In common with all European nations the variation was spoken of by the Frenchmen as a variation from the north towards the west; but the Chinese, who respected the south more than the north, considered that the needle pointed south, and counted from that pole of the magnet, calling the declination a variation to the east of south. This is the same thing in effect. The order of the Arabic words *zoron* and *aphron*, *south* and *north*, show whence the Arabs derived the invention. See MARINER'S COMPASS.

The variation was again noticed by Columbus in 1492, and Sebastian Cabot in 1540.

It does not appear that the other element of terrestrial magnetism, the inclination or dip, was known to the Chinese, though they must surely have noticed that a needle which hung in perfect equipoise before magnetizing was thrown out of balance when touched by the loadstone.

Robert Norman of London, a maker of compasses, was the first, so far as we know, to detect the *dip* and publish the fact; 1576. He contrived the *dipping-needle*, suspended on a horizontal axis, and found the *dip* at London to be 71° 50′.

Robert Halley, in 1700, published a chart, having lines passing through points of equal magnetic variation. His remark was that of a philosopher: —

"The nice determination of the variation, and several other particulars in the magnetic system, is reserved for a remote posterity All that we can hope to do is to leave behind us observations that may be confided in, and to propose hypotheses which after-ages may examine, amend, or refute."

Magnetic changes made Halley's chart obsolete in forty years, and it was reconstructed by the joint efforts of the English navy, East India Company, and Hudson's Bay Company. This chart was not satisfactory, and its discrepancies became positive inaccuracies as time wore on.

About 1756, John Canton, in England, made about 4,000 experiments for discovering and explaining the cause of the diurnal variation of the needle.

La Perouse sailed from France with instructions and instruments, intending to make special observations at remote stations in regard to the *variation* and *dip* of the needle. The lamented death of the Admiral and destruction of his vessels in 1788 prevented the results from being communicated to the scientific world.

M. Hansteen of Denmark undertook the subject in 1811, and in 1819 published his celebrated work "Upon the Magnetism of the Earth." He treated the matter historically and scientifically, making a variation chart for 1787.

The *agonic line*, or line of no variation, where the magnetic and geographical lines coincide, was discovered by Columbus in 1492, about 100 miles west of the Azores. Like other magnetic lines, it appears to have shifted. Hansteen's observations confirmed in great detail the position of Halley, that "the whole magnetical system is in motion; that the moving force is very great, extending its effects from pole to pole; and that its motion is not sudden, but gradual and regular."

The western line of no variation in Hansteen's chart, calculated for 1787, begins in latitude 60° to the west of Hudson's Bay, proceeds southeast through the North American lakes, passes the Antilles and Cape St. Roque till it reaches the South Atlantic Ocean, where it cuts the meridian of Greenwich in about 65° south latitude.

The eastern line of no variation (1787) is extremely irregular, having curious curves and contortions, indicating the action of local magnetic forces. It begins in latitude 60° south, below Australia; crosses that island, extends through the Eastern Archipelago with a double sinuosity so as to cross the equator three times; first passing north of it to the east of Borneo, returns, passing south between Sumatra and Borneo, and crossing the equator again south of Ceylon, from whence it passes to the east through the Yellow Sea. It then stretches along the coast of China, making a semicircular sweep to the west till it reaches the latitude of 71° north, when it descends again to the south, and returns north with a great semicircular bend which terminates in the White Sea.

Captain Sir James Ross reached the magnetic pole, latitude 70° 5′ 17″ north, and longitude 96° 46′ 45″ west, on the 1st of June, 1831. The amount of *dip* was 89° 59′. Horizontal needles refused to work, showing no sensitiveness. He erected a cairn of limestone rocks, inclosing a tin case with the record. The cairn may remain, unless the Esquimaux have removed it in search of plunder, but the magnetic pole has moved away.

The illustrious Humboldt gave the first start to a regular, systematic mode of recording magnetic observations, taking a large number in the course of his extensive travels and explorations, and calling the attention of the scientific world to the mode and importance of so doing.

Observatories, provided with magnetometers and meteorological instruments, and with apparatus for ascertaining the time and true meridian, are now working in concert in many distant stations: Berlin, Paris, Freiburg, Greenwich, Gottingen, Montreal, Melbourne, Cape Town, St. Helena, Simla, Madras, Bombay, Singapore, and probably many other places.

It is understood that the observations are made at the same instant of absolute time. Each day is divided into 12 equal periods of 2 hours each, termed the magnetic hours. The mean time at Gottingen is adopted; a tribute to the energy and skill of M. Gauss of the observatory in that city.

Mr. Brooke's system of photographic registry is adopted throughout.

Mag'net-o-mo'tor. A voltaic series of two or

Digitized by Google

more large plates which produce a great quantity of electricity of low intensity, adapted to the exhibition of electro-magnetic phenomena. — BRANDE.

Mag'ni-fy-ing-glass. A popular term for a convex piece of glass or a lens which has the property of magnifying. See OPTICAL INSTRUMENTS.

Mag'nus-hitch. (*Nautical.*) A kind of knot used on board ship.

Ma-goo'tee. An instrument used by the Pambatees or snake-charmers of the East Indies.

It is composed of a hollow calabash, to one end of which is fitted a mouthpiece similar to that of the clarinet. To the other extremity is adapted a tube perforated with several holes, which are successively stopped by the fingers, like those of the flute, while the player blows into the mouthpiece. In the middle of the instrument is a small mirror, on which the serpents fix their eyes while dancing.

Ma-ho'vo. An adaptation of the fly-wheel to the conservation of power during the times of light strain, to be used during periods when a greater power is needed. The invention of Captain C. Von Schubersky of Russia. See FLY-WHEEL.

Maid'en. A machine for beheading.

The Scotch guillotine, in use from 1550 to 1680, was copied from one at Halifax, England. It was sometimes called the *widow*. Both terms of grim and gross pleasantry.

The Halifax machine was an importation (as to design) from Italy, where it was used in the thirteenth century. Conradin of Swabia was decapitated by the *mannaia* at Naples, 1268.

The machine is supposed to have originated in Persia.

It was used in the execution of the Duc de Montmorenci at Toulouse, 1632. By the Germans during the Middle Ages, and by the Dutch in their colonies.

The Scotch *maiden* was imported into Scotland by the Regent Morton, who died by its axe, 1581. The murderers of Rizzio were executed by it in 1566; and the Marquis of Argyle, 1681.

The *maiden* was not as complete an instrument as the *guillotine*, which has a turning plank and track, with other devices for an artistic performance of tragedy. See GUILLOTINE.

Mail. 1. (*Weaving.*) One of the small brass eyes through which the *end* or worsted yarn passes in a *Brussels carpet-loom*, and by which it is lifted in order to form the loop which distinguishes the surface of that variety of carpet. See BRUSSELS-CARPET.

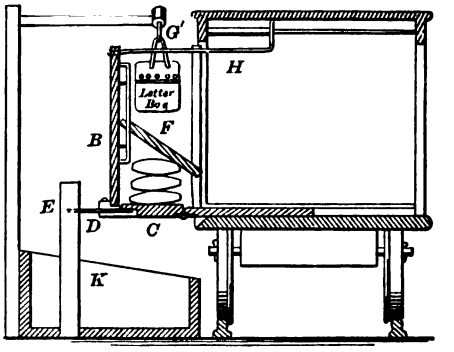
2. (*Nautical.*) A device consisting of interwoven rings, like mail-armor, used for rubbing off the loose fibers on cordage.

3. (*Armor.*) A flexible armor of rings or scales, covering the body or body and limbs, according to its extent.

Mail-bag. A letter-bag, usually of leather, but made of canvas, for containing newspapers and other printed matter for conveyance through the post-office. When of leather, the joints are closed with rivets; when of canvas, the seams are felled. The fastening of the mouth is by staples on one portion, which project through slits in the other, a strap being rove through the staples and locked.

Mail-bag Re-ceiv'er and Dis-charg'er. A device for receiving mail-bags from or delivering them to railway-cars in motion at stations along the road. Fig. 3030 shows one form of the device, in which the rod *H* attached to the car strikes the suspended mail-bag and draws it from the hook *G'*, when it falls upon the hinged incline *F* and is delivered into the car. In this way the mail is received by a car while under full headway, and simultaneously mail is delivered from the car by means of the trap-door *C*. The door *C* is disengaged by an arm *D*, which comes in contact with a post *E*, and the bags fall into the box *K*. When the receiving and delivering are done, the section *B* is slid back into the car.

Fig. 3030.



Mail-Bag Receiver and Discharger.

Worsdell's apparatus for receiving and delivering mail-bags and express matter to and from railway-cars, English patent, January 4, 1838. The bags to be delivered are suspended by their loops from two pins in a bar projecting from the carriage, from which bar also projects a prong or hook, and the bags to be received at the station are suspended from similar apparatus attached to a lamp-post. By the passage of the carriage past the lamp-post, the hook on the latter passes through the loops of the car bags and bears them off the pins, while the hook on the car in like manner carries off the bags from the station.

Other plans have scoops or cylinders on the car which pocket the mail-bag suspended from a crane or lying upon a support from which it may be shoveled, picked, or shot by the device on the car. A somewhat similar converse arrangement deposits at the station the bag carried by the car.

Mail-coach. A carriage chartered by the post-office department or hired to carry postal matter.

Mail-coaches were introduced by Robert Palmer of Bristol, England, in 1784.

Mail'ing-ma-chine'. A machine for attaching addresses to newspapers, etc., for transmission by mail. See ADDRESSING-MACHINE; also, Ringwalt's "Encyclopædia of Printing," pp. 226, 227.

Mail-net. (*Fabric.*) A form of loom-made net, which is a combination of common gauze and whip-net in the same fabric. The whole fabric is a continued succession of right-angled triangles, of which the *woof* forms the basis, the *gauze* part the perpendiculars, and the *whip* part the hypotenuse. The gauze and whip parts are stretched on separate beams.

Main. A principal part or portion.

1. (*Hydraulics.*) *a.* A large or principal water or gas pipe. The smaller are termed *supply* or *service* pipes or branches.

b. A large channel or ditch.

2. A banker's shovel for coin.

3. (*Nautical.*) The middle or principal mast, hatchway, etc., in a three-masted vessel.

In all *two-masted* vessels, except the *yawl* and *ketch*, the main is the aftermost mast. A *brig* or *schooner* has a fore and a main mast.

With a *yawl* or *ketch*, the forward mast is the

Digitized by Google

larger, and is called the *main*-mast, the other being the mizzen.

In all rigs the main-mast is the principal and tallest mast.

The term *main* characterizes the sails, yards, booms, standing and running rigging, and other furnishing of the main-mast; such as *main sail* and *yard*, *main-topsail* and *yard*, *main-topgallant*, *main-royal*, *main-boom*, *main-stay*, *main-top*, *main-sheet*, etc.

The term is also applied to objects in the vicinity of the mast; as, the *main-hatchway*, *main brace*, *stay*, *keel*, etc.

Also to principal parts which are of central position, greater size, prominence, or importance; as, *main-deck*, *main-keel*, *main-breadth*.

In other than nautical matter the word is similarly characteristic.

Main-breadth Line. (*Shipbuilding.*) A line on the surface of the vessel cutting each of the cross sections at the point where its breadth is greatest.

In vessels having a "straight of breadth" vertically, there are two main-breadth lines, at the upper and lower boundary of the straight of breadth respectively.

Main-cen'ter. (*Steam-engine.*) In side-lever engines, the strong shaft upon which the side-levers vibrate.

Main Check-valve. (*Steam-engine.*) A valve belonging to the Giffard injector, to prevent water running out of the boiler should anything go wrong with the injector.

Main-coup'le. (*Carpentry.*) The principal truss in a roof.

Main-deck. (*Shipbuilding*) The deck next below the *spar-deck* in frigates and 74's.

Main-ham'per. A large hand-basket.

Main-in-clos'ure. (*Fortification.*) The body of the place.

Main-links. (*Steam-engine.*) The links in the parallel motion which connect the piston-rod to the beam of a steam-engine.

Main-piece. (*Shipbuilding.*) *a.* The principal piece of the head. It is stepped into the stem-piece, and is notched for the reception of the heel of the bobstay-piece. See STEM.

It is also called the *lace-piece*.

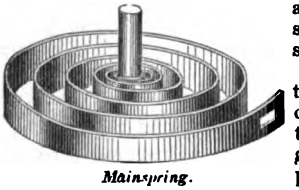
b. The longest piece of the rudder, to which the helm is attached.

Main-pin. (*Vehicle.*) A *bolster-pin*; *king-bolt*.

Main-plate. The principal plate of a lock.

Main'spring. 1. (*Horology.*) The going spring of a watch, spring-clock, musical-box, alarm, or other spring-driven instrument.

Fig 3031.



Mainspring.

In the watch, it is termed main, because of its major importance, and to distinguish it from the pendulum or balance-spring, which gives the recoil movement to the balance.

2. (*Fire-arm.*) The spring in a gun-lock which drives the hammer.

Main-work. (*Fortification.*) The enciente or principal works inclosing the body of the place.

Mait'land Cord. (*Weaving.*) A cord extending along the wooden shafts of leaves, to which the heddles are fastened with knots.

Ma-jol'i-ca-ware. A species of fine pottery, composed of clay thickly and opaquely enameled, suitable for receiving brilliantly colored figures; fabricated at Ferrara (1436) and at Passaro (1450). It is sometimes called "*Raffaelle* ware"; this may be from the fact that Raffaelle Sanzio d'Urbino furnished designs for the ornamentation of some specimens, or from one Raffaelino del Colle, a skillful workman at Urbino. The name is a corruption of *Majorca*, into which island (in the twelfth century) the Moors introduced the manufacture of a species of ware decorated with brilliant colors.

Majolica, until the time of Lucca della Robbia, was glazed with a plumbiferous glaze (*mezza majolica*), but Robbia invented a beautifully white, durable, enameled, stanniferous glazing. Giorgio, by the combination of mineral colors, succeeded in producing beautifully iridescent ruby and golden tints. Existing specimens of his manufacture are very costly. After the time of Fontana (about three hundred years ago), who carried the manufacture to perhaps its highest perfection, the art began to decline, the production finally ceasing altogether.

Of late years, the Staffordshire potters have succeeded in reproducing this ware, and slabs, friezes, tablets, vases, flower-pots, and other articles are now made of it.

Make-up. (*Printing.*) To break matter in columns or galleys into suitable length for pages.

"Mak'ing"-felt. (*Paper.*) That felt of a cylinder paper-machine on which the web of pulp is taken from the *making*-cylinder, at the point where the couching roller bears upon the latter. In contradistinction to a mere *carrying*-felt.

Mak'ing-i'ron. (*Shipbuilding.*) A large calking-iron with grooves lengthways of its face, used for the final driving of oakum into the seams. The iron is held by one man, and driven by another by means of a beetle; the process is called *horsing-up*. A *horse-iron*. After the making-iron, the seams are payed with melted pitch.

Mal'a-chite. *Mountain green.* A native carbonate of copper.

Ma-lax'a-tor. A mixing-mill. A cylinder having a rotating shaft and stirring-arms to incorporate materials.

Coignet's *malaxator* for incorporating the ingredients of his concrete (see BÉTON) is supplied with the materials in graduated proportions, the energetic working permitting the use of a much smaller quantity of water than usual.

Mortar-mills, *pug-mills*, and many other machines come under this description, e. g. machines for mixing the ingredients of pills.

Hyde's soap-making machine, 1870, is an instance in which the grease, resin, and lye are incorporated by a revolving stirrer in a cylinder, the operation being continuous.

Mal'kin. A sponge with jointed staff for ordnance.

Mall. A heavy beetle. See MAUL, and Fig. 3031.

Mal'le-a-bil'i-ty. The quality of adaptedness to be drawn into thin plates by hammering; as *ductility* is the wire-drawing capacity. See DUCTILITY for comparative statement.

Mal'le-a-ble Cast-i'ron. Iron cast from the pig into any desired shape, and afterwards rendered malleable, or partially so, by annealing.

A great variety of articles are thus produced in a more economical and correct manner than they could be by forging. Such are bridle-bits, snuffers, parts of locks, various forms of builders' and domestic hardware, some kinds of culinary and other vessels, pokers, tongs, and numerous other things. Many of these are subsequently case-hardened and polished.

The art of softening cast-iron and working it, and

Digitized by Google

afterwards hardening it again, appears to have been found out by Reaumur, though we have no record of the process by which it was effected.

Malleable-iron castings are rendered externally soft by the abstraction of carbon, by which they are reduced nearly to the condition of pure malleable iron, but do not possess the fibrous structure which is acquired by hammering and rolling.

In England they are made from the rich Cumberland iron, and are at first extremely brittle. To render them malleable, they are inclosed in iron boxes and surrounded with pounded iron-stone, or some of the metallic oxides, as scales from the forge, common lime, or some absorbent of carbon, used either together or separately. The boxes are placed in the furnace, subjected to a strong heat for about five days, and allowed to cool gradually within the furnace.

The time and other circumstances determine the depth of the effect; thin pieces become malleable entirely through, admit of being readily bent, and may be slightly forged; thicker pieces retain a central portion of cast-iron, but in a softened state, and not so brittle as at first. On sawing them through, the exterior coat of soft metal is perfectly distinguishable from the remainder.

The inventor of the process of rendering articles of cast-iron malleable was Samuel Lucas of Sheffield, by whom it was patented in 1804.

As described in his specification, his process was nearly identical with that above described, except that the castings were placed directly in the furnace, instead of being inclosed in boxes.

The Siemens regenerative gas furnace is largely used in England now for heating the annealing-oven in which the crucibles containing the cast-iron articles are placed.

As arranged for this purpose, the furnace has four longitudinal main flues divided by partitions into a number of smaller flues. The two exterior flues receive the heated gas and the two interior ones hot air. Over these is a closed arched muffle, in which the annealing-pots are placed. The hot gas and hot air, being kindled, pass beneath at the sides and over the top of the arch of the muffle.

The furnace is never permitted to cool entirely. The pots are allowed to cool on the floor.

The German makers of malleable-iron castings are said to use a pig-iron measurably free from sulphur and phosphorus, which they melt in plumbago crucibles with porcelain covers, containing about 30 kilogrammes (66 pounds). No blast is used; the natural draft of the furnace-chimney being considered sufficient. A high heat at the moment of pouring is essential to a successful cast, and the precise moment for this operation is ascertained by plunging a bar of red-hot iron into the crucible. The crucibles are raised by tongs, and the pouring performed as quickly as possible. When sufficiently cool, the castings are placed in boxes alternately with layers of red hematite, and subjected to the heat of the furnace for from 3 to 5 days, according to size, and removed after the furnace has been allowed to gradually become cool.

An approved mode in the United States of rendering castings malleable is as follows: —

When taken from the mold they are washed with dilute sulphuric acid to remove the rough coating of vitrified sand from their surfaces, and the ragged burrs sometimes left at the junction of the two parts of the mold are chipped off, after which they are packed with the "scale," derived from iron bars in the process of rolling, in square iron boxes (technically called *pots*) of the dimensions of about 15 × 18 inches, of which one is placed on top of another, the joints carefully luted. They are inserted into the furnace in pairs, and subjected to a cherry-red heat for about eight days; the heat is somewhat slackened toward the latter part, after which the doors are thrown open to allow them to cool. When removed from the pots the castings are coated with a rough crust, which is removed by abrasion in tumbling-boxes.

Mal'le-a-ble I'ron. Iron sufficiently pure to be drawn out into bars and welded.

Iron, in the ore or roasted, is in the state of oxide, and (omitting from the consideration the presence of foreign matters) to obtain it pure merely requires the separation of the oxygen. This may be done as a chemical process by heating the oxide to a heat below redness in a glass tube through which hydrogen is then passed; the hydrogen and oxygen unite to form aqueous vapor, and pure iron remains. This is measurably true of certain qualities of ores, but pig-iron is sometimes found to contain 10 to 18 per cent of foreign matters, — principally manganese, carbon, and silicon, — also phosphorus and sulphur, both of which latter it is almost impossible to entirely remove by puddling.

All these have to be got rid of to produce pure malleable iron, unless the ore is of extraordinary purity.

At a moderate red heat, a mixture of finely pounded charcoal and oxide of iron will have the effect of eliminating the oxygen, and this process is believed to have been in use in ancient times in the island of Elba. The ore is remarkable for its freedom from earthy impurities, and after breaking into small pieces was imbedded in charcoal on the floor of a reverberatory furnace. After the oxygen was separated by the action of the charcoal, the temperature was raised to a welding heat, and the pieces of ore, now in the state of porous iron, were caused to adhere by hammering, and were drawn into bars. This is a process of obtaining malleable iron direct from the ore, and has been repeated by Mushet.

There is considerable analogy between this and the native East-Indian practice, where the broken ore or magnetic-iron sand is placed in alternation with bamboo charcoal, and a pasty mass of crude iron obtained, whose malleability is sometimes sufficiently great to enable it to be hammered into small bars without a second operation. The bellows used are made of skin, are worked alternately, and discharge by separate holes through the clay tuyere which is introduced at an angle near the bottom of the upright furnace.

These Indian furnaces are miniatures of those in Styria, described in the work of Jars, a French metallurgist, 1750. The ores there worked have a notable percentage of manganese, which affects the result, being seemingly favorable to the retention of a certain amount of carbon, but resisting the combination of the larger amount necessary to make cast-iron.

Styria was not the only European country in which the simple furnace just described was used for smelting iron ore, for those of Sweden and Norway, 300 years ago, were of substantially the same character. The iron obtained from them was a spongy mass, which was drawn out at intervals by tongs, hammered gently and cautiously, and then more energetically, to press the particles of iron into contact and squeeze out the intermixed slag. The mass thus obtained was cut up into smaller pieces, which were repeatedly heated and hammered till a sound bar of nearly pure iron was obtained.

The size of the furnace, and especially its hight,

Digitized by Google

was increased in order to save fuel, as the ore and flux piled in above were heated by the outgoing caloric current, preparatory to being subjected to the direct action of the blast. The bellows were also proportionately increased in power. This change, probably adopted from motives of economy, changed the result, and rendered necessary new processes to bring the iron to a malleable state. As the iron descends through the furnace for 30 feet it is subjected to the action of the fuel, and has time to part with its oxygen, and also absorb from 3 to 5 per cent of carbon and 2 to 4 per cent of silicon. This addition renders it more fusible, and it sinks to the bottom of the crucible in a carbonized state, differing in respect of its greater proportion of carbon from the spongy and less fusible mass of iron, such as was produced by the processes above referred to as carried on in ancient times in Elba, both anciently and more lately in India and Styria, and elsewhere.

This clears up much of the difficulty in the reading of the ancient records, where iron always appears in a malleable form, the tools used by the workers in iron consisting invariably of the bellows, hammer, and anvil. It appears that fusible cast-iron was first considered immediately useful after the size of the furnaces had been so increased as to prevent the production of the more or less malleable and purer article incident to the furnaces on a small scale, which we have just above cited.

The new production, instead of remaining a spongy mass in the midst of the coal and slag, to be hauled thence by tongs and be subjected to the hammer to clear it of foreign matter and condense it, ran down like a fluid to the bottom hearth, and found its way out of a hole, running into a form according to the shape of the hollow in the ground which received it. By this means the smelter found he could withdraw the iron, without tearing out the front of his furnace for each bloom.

This new form, cast-iron, being brittle under the hammer and unsuitable for almost all the known uses of iron at the day when the discovery was made, it became necessary to subject it to a farther process, in order to burn out the greater portion of the carbon and silicon and render it malleable. The refining process observed by M. Jars in Sweden, in 1750, is identical with that described by Aiken in 1836 as having been used in India for a length of time not now readily ascertained.

The block of crude iron is laid, covered with charcoal, on the floor of the furnace, with one end projecting over the crucible, a little above the mouth of the tuyere. In this situation the block softens and soon falls down in a state of half-fusion ; a man with an iron bar then draws the remainder of the iron block forward, advancing it from time to time, till the whole has fallen into the crucible.

It is then dragged out, glowing hot, and hammered on an anvil to separate the scoriæ ; being divided, it is again heated and hammered until it is rendered quite malleable.

A modification of this process was adopted in Sweden, being derived from the puddling process of Cort, and consisted in covering the metal in the crucible with scoriæ and stirring it continuously with an iron bar. Jets of flame arose, and the metal solidified. Berzelius explained the action in this way : The scoriæ contained oxide of iron vitrified with silica and other earthy substances containing oxygen, which, reacting on the carbon of the iron, separated it in the form of carbonic oxide.

More modern forms of refining have superseded the Indian and Swedish plans above cited, the broken pig-metal being placed on the hearth of a furnace, covered with coke and slag, and a blast turned on till the metal is melted. It is run into slabs, and the metal obtained is white, hard, compact, and brittle.

The puddling-furnace was invented by H. Cort of Sheffield, England, his patent being dated in 1784. See PUDDLING-FURNACE.

One process of converting pig into malleable iron, as practiced in England, is as follows : —

The pigs are melted in the fining-furnace, by which the iron is deprived of part of its carbon and a larger portion of its silicium. The molten metal collects in a cavity at the bottom of the hearth, and is drawn off into a cast-iron trough in which it speedily cools. By this process it is converted into a white cast-iron termed *fine metal*. This is broken up and transferred to the puddling-furnace, in which the decarbonization is completed.

The puddling-furnace is of the reverberatory class, and is provided with openings for working the metal while in a fluid or semi-fluid state, and for charging and clearing the furnace.

The charge of *fine metal* is piled up on the sides of the hearth, the center of the sole being left clear for working and allowing a circulation of air around the charge. A portion of rich slag and iron scales is added. As the metal melts, it is stirred with an iron rod, so as to expose fresh portions to the air until the whole mass is brought into a uniform pasty condition, when the fire is lowered. The metal is constantly stirred with an iron paddle, gradually losing its consistency, until it becomes sandy or *dry*, as it is termed by the puddler, who continues to work it until it becomes uniformly granular.

The heat is then increased, causing the particles to agglutinate. A part of the slag is drawn off, when the workman proceeds to *ball up*, that is, to form the iron into balls. This is effected by taking up a small portion on the end of the paddle, which is manipulated so as to cause other portions to adhere to it until a ball has been formed weighing 60 or 70 pounds. This is detached from the paddle, and other balls formed in a similar manner until the whole charge has been balled. When this has been done, each ball is moved into the hottest part of the furnace by means of a kind of rake called a *dolly*, and the fire is urged in order to weld the particles together. The balls are then removed from the furnace by means of tongs and conveyed to the *shingling-hammer* or the *squeezer*, by which the slag is pressed out and the metal consolidated. In this state the ball is called a *bloom ;* and while it is still at a red heat it is passed between two sets of rolls, the first called the *roughing*-rolls and the second the *finishing*-rolls, which latter are grooved corresponding to the section to be given to the bar.

The iron in this state is adapted for railway rails, which are made by successively drawing the bar through rolls of section similar to that of the rail, but gradually decreasing in size. To produce good bar-iron, the bars from the roughing-rolls are cut into short lengths by shears, and *piled* or *fagoted* together in a reverberating furnace until they are at a welding-heat, when they are drawn through a series of finishing rolls of section adapted to the required shape of the bar. See PUDDLING-FURNACE ; ROLLING-MILL ; IRON, ANGLE, etc.

Mal'le-a-ble-i'ron Cast'ings. Small cast-iron articles are made malleable, their brittleness being thus removed, by packing them in powdered hematite (peroxide of iron) in tight fire-brick cases, and subjecting them to a continued red heat for about a week. They are then allowed to cool slowly.

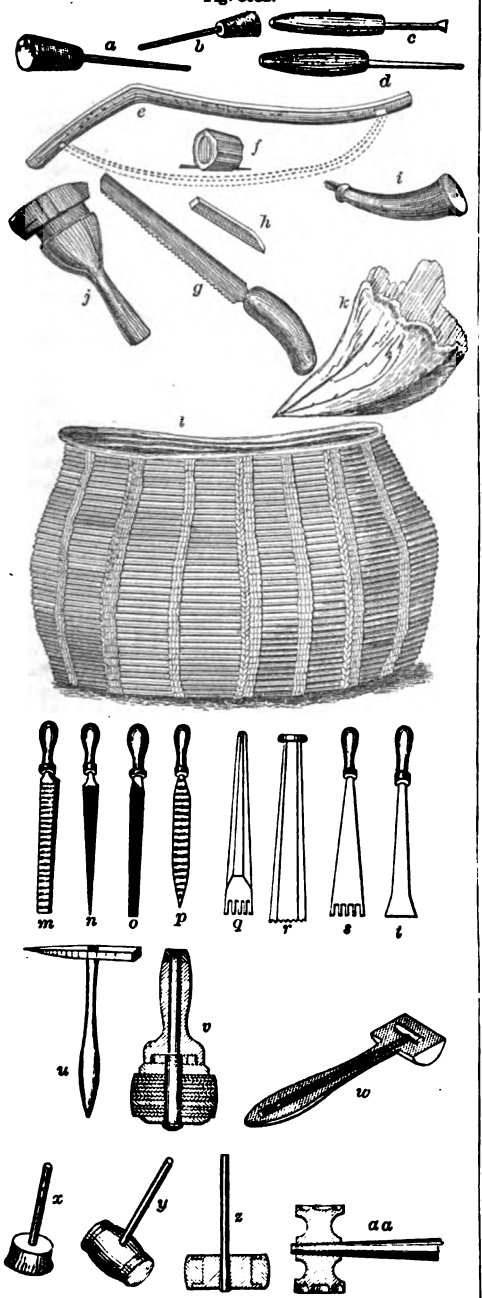
The oxygen of the hematite combines with and removes a part of the carbon of the iron.

Digitized by Google

It is the converse of the process in which wrought-iron is closely packed with charcoal in a converting furnace, in order that its deficiency in carbon may be supplied, converting the bar-iron into steel. See MALLEABLE CAST-IRON; CEMENTING-FURNACE.

Mal'let. 1. A hammer of wood, smaller than a maul. Formerly, in the absence of metal, *celts* or hammers of stone were used. Mallets and wedges of stone were used in ancient Egypt, and were found in the pyramids of Cheops and Ghizeh.

Fig. 3032.



Mallets, Mauls, and allied Tools.

Among other remnants of other centuries, gathered by Mr. Burton in Egypt, he found an old mallet in Thebes; it was in a basket along with drills, bow, chisels, an oil-horn, a saw, and a nail-bag, and had been locked up in a dry and dusty tomb at a time when Greece had not felt the light of science, and centuries before Romulus and Remus. Perhaps the workman had been putting the finishing touch to some of the fittings of the tomb, and accidentally left it inside when the door was closed, as they supposed, forever, or until the shell of the body was revived to receive its old tenant. The successors of the carpenter in the twentieth generation may have suffered from the wrath of Cambyses.

a b c d are chisels and drills.

e a drill-bow, the leather string lost.

f, whorl of the drill. *g*, saw; *h*, hone.

i, oil-horn; *j*, mallet, much worn.

k, skin nail-pouch. *l*, the basket in which the tools were contained.

The collection belonged to Mr. Burton, and is now in the British Museum.

The modern mallet is preferably of boxwood, but apple-tree, pear-tree, dogwood, gum, beech, or locust makes good mallets. *v* is a mallet made of thicknesses of raw-hide firmly pressed together by the center bolt. *w* has a rubber body upon a metallic skeleton.

2. (*Nautical.*) *a.* A *calking-mallet* is one used with a *calking-chisel* or *making-iron* to drive oakum into the seams of a vessel.

b. A *serving-mallet* is a cylindrical block of wood, by which spun-yarn is tightly coiled around a hawser or rope.

3. (*Dentistry.*) A plugger for compacting filling in carious teeth. See DENTAL-PLUGGER, Figs. 1610, 1611.

4. A striker for balls in games. A *croquet* mallet.

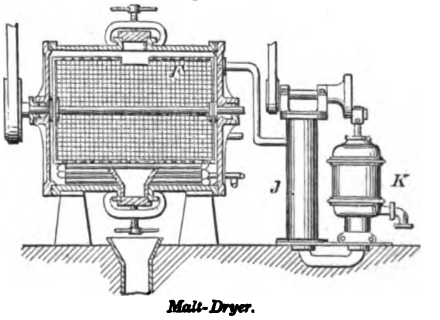
The *electric mallet*, in which the impulse is given by means of a galvanic circuit acting upon a magnet to oscillate an armature, or to move the magnet itself to and from an armature which forms the punch, is described under PLUGGER.

5. (*Surgical.*) A hammer used with a gouge in cutting bones.

Malm-bricks. The name given to those bricks, made in the neighborhood of London, in which the clay is pulped, mixed with cream of lime, and incorporated with breeze before molding. Breeze is a casual mixture of cinders, ashes, and fine coal, such as is gathered by the dustmen of London, and forms a part of the combustible material by which the bricks are burnt in the clamp. See BRICK.

Malt-dry'er. A device to hasten the drying of malt by artificial heat. Fig. 3033 shows a machine in which the malt is agitated and overturned in an

Fig. 3033.



Malt-Dryer.

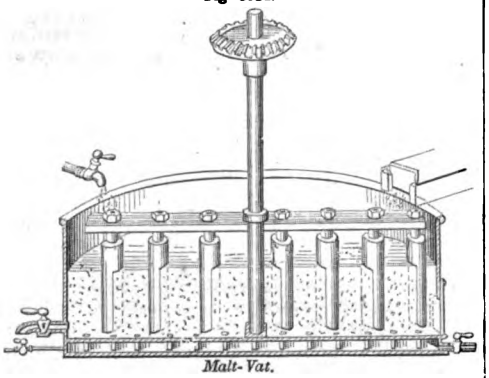
air-tight vessel from which all moisture is withdrawn by an air-pump, while its contents are exposed to heat. The wire-gauze cylinder *F* is within the air-tight vessel, and is caused to revolve, and so stir and mix its contents. *K* is the air-pump and *J* a condenser. The air-tight vessel has man-holes above and below, secured by man-hole covers and bridges, through one of which the malt is received, and discharged into the hopper below by the other.

Fig. 3034.



Malt-Vat.

Malt-floor. The floor of an *oast* or malt-drying room.

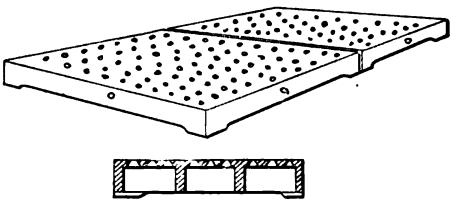
Malt'ing-ap'pa-ra'tus. (*Brewing.*) A vessel in which ground malt is steeped to make the infusion known as *wort*; this, with the addition of decoction of hops and fermentation, becomes beer. The malting-vat shown in Fig. 3034 is provided with a false bottom, forming a steam-chest. Within the vessel revolves a shaft armed with blades. A portion of the blades are so set as to move the grain towards the circumference, and the other blades are so arranged as to move the grain towards the center.

Malt-kiln. A heated chamber in which malt is dried, in order to check the germination of the grain after having undergone the preliminary processes of *steeping*, *couching*, and *flooring*. An *oast*.

In the first of these processes, the barley is placed in a cistern, and sufficient water let in to cover it. This water is changed after having remained a certain time, to avoid fermentation. When the grain has steeped until it has imbibed the proper quantity of moisture, — in England the law requires that it shall remain in steep forty hours, — during which time it greatly increases in bulk and weight, on an average nearly fifty per cent, it is removed from the cistern and arranged in a rectangular heap called the *couch*. Here it remains about 26 hours, gradually increasing in temperature and parting with its moisture. During this process small roots begin to make their appearance. The growth of these is checked and the temperature of the heap lowered by *flooring*, or turning and spreading it out into a thinner layer, gradually reducing its depth from 16 to 3 or 4 inches. The flooring occupies about 14 days. About a day after the sprouting of the roots, the stem begins to make its appearance, and is allowed to grow until it reaches the end of the seed, when its farther progress is stopped by drying in the kiln.

The ordinary kiln is a chamber floored with a perforated iron plate, and having a vent in the roof for the escape of fumes. This is heated by a furnace in an apartment below, the hot air rising through the holes in the iron plate and passing through the malt. The temperature is at first about 90°, which is afterwards increased to 140° or more. For the completion of this process about two days should be allowed, during which the roots fall off and are separated from the grain by allowing the latter to run down a shoot, at the end of which is a screen w ch does not permit the grain to pass. The malt is then spread out to mellow or become soft and mealy by a slight absorption of moisture.

Fig. 3035.

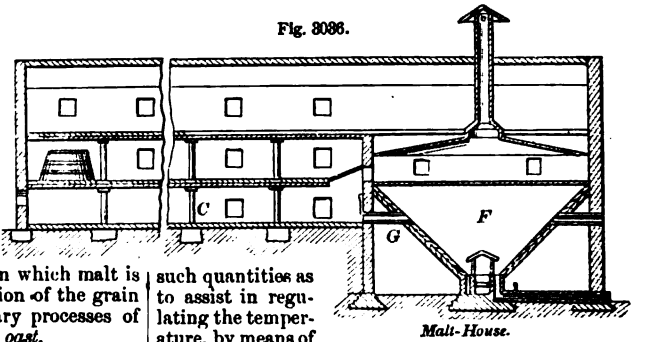


Malt-Kiln Floor.

Fig. 3035 shows part of a floor composed of plates made of malleable cast-iron, strengthened on their under side by ribs crossing each other at right angles and uniting with a marginal ledge surrounding them, so as to be bolted together to form the floor.

In the kiln, Fig. 3036, air for supply of the furnace is drawn through the malting-chamber *C* in such quantities as to assist in regulating the temperature, by means of draft pipes or tubes *G* connecting the chamber with the heating-chamber *F* of the kiln.

Fig. 3036.



Malt-House.

In the apparatus, Fig. 3037, the grain is stirred and turned by mechanical means, while exposed to the heat of the kiln. A furnace below and layers of steam-pipe within heat the kiln, and the vapor generated is condensed in a separate chamber, which connects by a pipe with the dome.

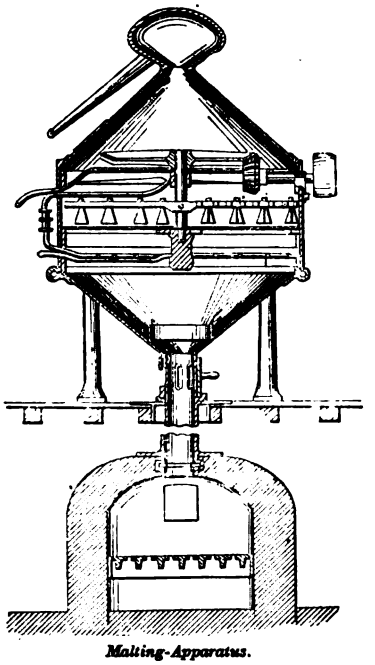
Man'a-cles. Handcuffs or *nippers* for criminals. The two pieces of metal are hinged together, the upper portion of which is curved so as to fit the wrist, and the lower portion is straight except at a point near its outer end, where it is slightly bent. Fig. 3037.

Man'da-rin'ing. Giving an orange color to silk or wool by the action of nitric acid, which partially decomposes the surface of the fiber.

Man'do-lin. (*Music.*) A stringed instrument played by the hands. It has 4 double strings, that is to say, four times two strings in unison and tuned in fifths like the violin. It is written on the G clef. The E strings are of catgut; the A strings of steel; the D strings of copper; and the G strings of catgut covered with silver-wire. The compass is about 3

Digitized by Google

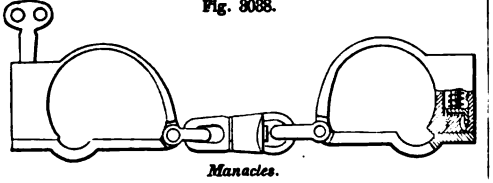
Fig. 3037.



Malting-Apparatus.

octaves. The strings are put in vibration by a plectrum held in the left hand. See *Mandola*, Bonanni, *Istromenti Armonici*, Roma, 1776; plate LV.

Fig. 3038.

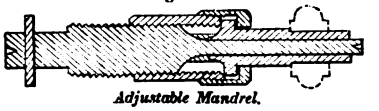


Manacles.

Man'dore. (*Music.*) A four-stringed lute.

Man'drel. 1. (*Lathe.*) Often incorrectly spelt mandril, which unfortunately is a short-tailed baboon with a red and blue face. The *cynocephalus*. *a*. An arbor or axis on which work is temporarily placed to

Fig. 3039.



Adjustable Mandrel.

be turned. The arbor which revolves in the head-stock of a lathe and carries the upper pulley, and also the chuck or face-plate, if one be used. The example is an adjustable mandrel, having keys which fit in inclined longitudinal seats in the mandrel, and which are adjustable therein by a screw-sleeve on the shank.

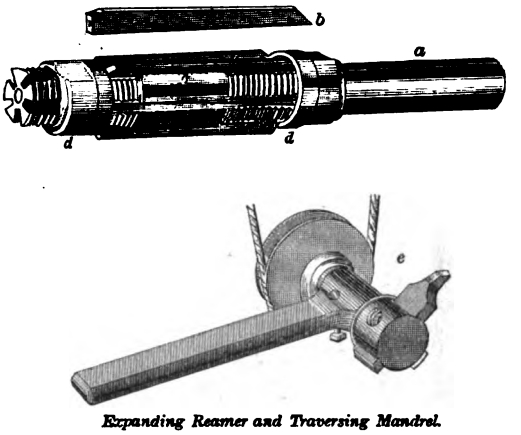
Traversing mandrels *e* are used in connection with a lathe, and are driven by gearing from a countershaft overhead. The one illustrated may be screwed into the tool-post of the slide-rest, and the belt from the countershaft carried on the small pulley, which runs at 1,500 revolutions per minute.

The use of the tool is to make ornamental designs or circular carving on all kinds of turned work.

2. (*Boring.*) The arbor *a* of Critchley's expanding mandrel for reaming has five grooves fitted with keys, cutters, or expanding tools *b*, according to the nature of the work or the office of the tool.

A screw-thread is cut on the body of the mandrel, and a portion of it is left in the center, as at *c*, to

Fig. 3040.



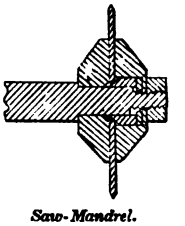
Expanding Reamer and Traversing Mandrel.

strengthen and prevent springing. The cutters are beveled at each end and confined in their places by nuts *d*, so that it is only necessary to slacken them off and slide the cutters down in the tapered grooves to expand or counteract their outside diameters, and thus adapt them to various dimensions of work.

3. The revolving spindle of a circular saw or a circular cutter.

As the annular bush slips upon the mandrel, its conical face penetrates the central orifice in the saw, and maintains the concentricity thereof; an elastic packing intervenes between the bush and the end collar.

Fig. 3041.



Saw-Mandrel.

4. (*Forging.*) A round rod of any desired diameter, used in giving an interior cylindrical form to a forging, as a *nut* or hollow spindle.

5. (*Casting.*) A plug around which a body of metal or glass is cast.

Man'drel-lathe. A lathe adapted for turning hollow work, which is clasped by a chuck on the end of the mandrel in the head-stock; or for turning long work which is supported by the head and tail centers. It is the usual form of well-made lathes for metal and wood turning. See LATHE.

Man-en'gine. A mechanical lift for raising and lowering men in the shafts of mines. The same device is used in factories, and in some hotels.

The modes of construction vary; the most secure is an application of the screw or the piston; the most rapid, a platform raised by rope and drum. (See CAGE; WATER-ENGINE; ELEVATOR.) One of the simplest is the reciprocating vertical rod with platforms at intervals.

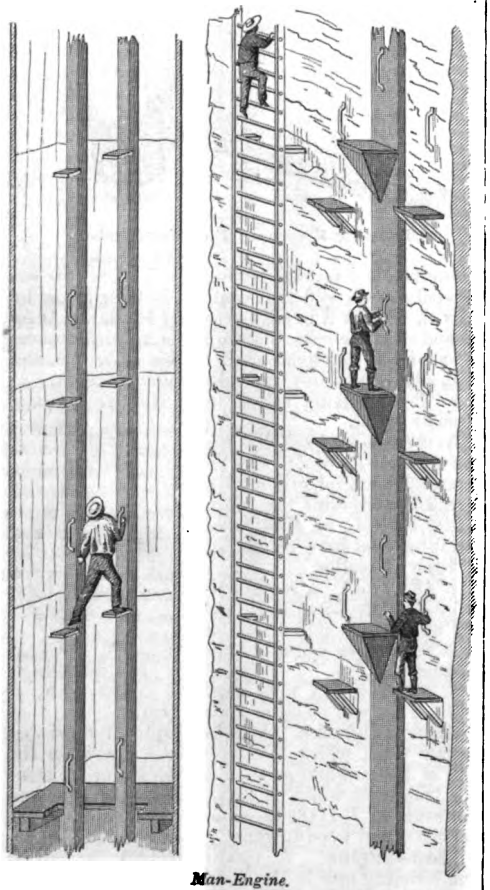
The latter form is specifically known as the man-engine, and was invented in the early part of the present century by Bergmaster Dörrell of Clausthal, in the Upper Hartz, who used two pump-rods, which, side by side, went up and down a shaft, and fixed to them small platforms and handles at all those points of the rods which came opposite after every stroke. So, by

Digitized by Google

simply changing his stand after each stroke, from one rod to the other, a man would be lifted up to the surface. The plan was adopted in Germany, Belgium, France, England, but the "engine" was driven by special machinery, that at the deep silver-lead mines of Przibram in Bohemia having, since 1854, a steam-engine with two cylinders and cataract gear. The man-engine reaches a depth of 2,400 feet, and 3,000 men go up and down it daily, in three shifts of 8 hours each. It has a stroke of 10 feet. A similar engine at another shaft in the same mine has a stroke of 12 feet.

At the Trevesan mine in Cornwall, which is 300 fathoms deep, a man-engine has been constructed for lifting the miners and lowering them to their

Fig. 3042.



Man-Engine.

work, a depth of 240 fathoms. It has two parallel vertical rods, which are provided with stages or platforms and are reciprocated past each other. The stages are 2 fathoms apart, and each rod receives a motion through the same distance.

A man stepping on to the lower platform, say No. 1 of the left-hand rod, is raised by the lifting of the rod which brings him to the level of platform No. 2 on the other rod, which is at its lowest position; on to this he steps. When platform No. 2 rises he reaches the level of platform No. 3 on the opposite rod, and so he keeps stepping from one side to the other, rising 12 feet between each step. The platforms are opposite to each other at the dead points of the engine-crank, and thus pause for a slight space of time while the miners step off one and on to the other. A string of men thus ascend with merely the labor of stepping from one platform to another. The descent is the converse operation, in such case the man stepping on to the platform which is about to descend.

In a modified form, one set of steps is on the vertically reciprocating rod and the other set fixed on the side of the shaft. This plan is only half as fast as the other, the miner pausing half his time and ascending at intervals.

In the "Devon Great Consols" mine, England, the shaft of 1,020 feet depth has landings at intervals of 12 feet, and openings through which the timber rod of 8 inches square descends, having on it steps 18 × 15 inches, the openings in the landings being 27 × 24 inches. See left portion of Fig. 3042.

The men in ascending occupy one side of the landings, whilst those descending use the opposite side, which obviates any confusion in stepping on and off. It is evident that as the stroke of the engine is 12 feet, and as it makes five strokes per minute, a man descends at the rate of 60 feet per minute, and therefore takes 1,020 seconds to descend 170 fathoms; and if 100 men require to descend to that depth, the hundredth man will necessarily be 1,188 seconds behind the first, and the time requisite for the whole will be 1,188 + 1,020 = 2,208 seconds, or 36.8 minutes. Thus, when the engine is working full, each step in rising carries a man and in descending carries a man, a man landing on one side of the platform and giving place to a man on the other side who steps on to descend, as the shifts of men pass each other in the shaft.

Man'ga-nese'. Equivalent, 27.6; symbol, *Mn.*; specific gravity, 8; fuses at the same heat as wrought-iron. It is a grayish-white, brittle, hard metal, resembling cast-iron. It is used in arts and manufactures in several ways.

It is the *glass-maker's soap*, used to correct the green color of glass, which is owing to the presence of protoxide of iron, converting it into the comparatively colorless peroxide.

It is also used in the Bessemer and similar processes, to decompose the oxide of iron. *Spiegeleisen*, which contains a notable quantity of manganese, is used for this purpose where conveniently attainable. See BESSEMER PROCESS, p. 277.

Man'ger. 1. (*Shipwrighting.*) A space abaft the *hawse-holes* on the working-deck, bounded by planks lying athwartships, and serving to prevent the water that comes in at the *hawse-holes* from flooding the rest of the deck.

2. (*Husbandry, etc.*) A feeding-trough for grain; usually accompanied by a rack for hay.

Man'gle. A machine in which damp clothes are smoothed by roller pressure. *a* represents the old-fashioned mangle, which had a box weighted with stones and reciprocating upon rollers which ran back and forth upon the clothes, spread upon a polished table beneath.

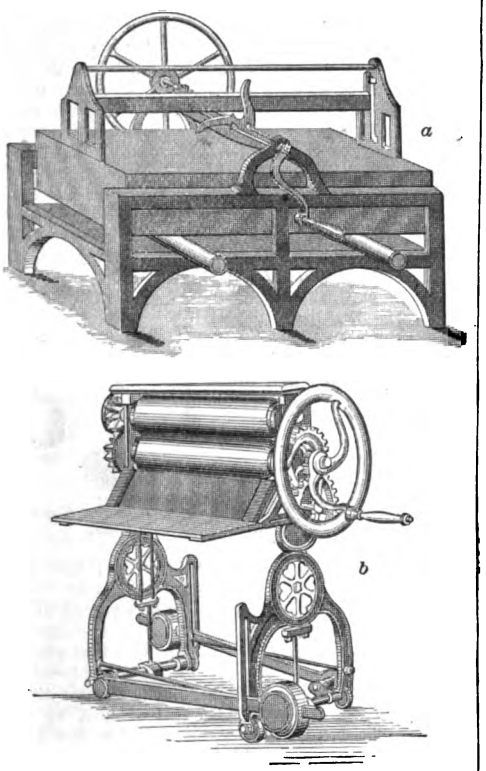
b is an improved form of mangle on the principle of the wringer. The clothes are passed between pressure-rollers driven by gearing.

In Fig. 3044, a series of rollers is disposed around a central drum, so that the garments are not subjected to undue pressure at but one or two points, as in the case of mangles having only two rollers.

On the frame axis of the large roller is an open wheel gearing into pinions on the axes of the smaller rollers; each of the latter has a rubber spring which

Digitized by Google

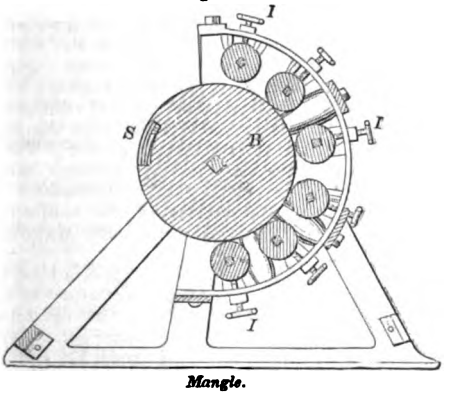
Fig. 3043.



Mangles.

presses it towards the large roller, and the pressure of the spring is regulated by a thumb-screw *I*. The large revolving roller has a clamp *S* for the edge of the clothes as they are fed between that roller and the series of rollers that abut upon it. This is to prevent the necessity of feeding the clothes at the

Fig. 3044.



Mangle.

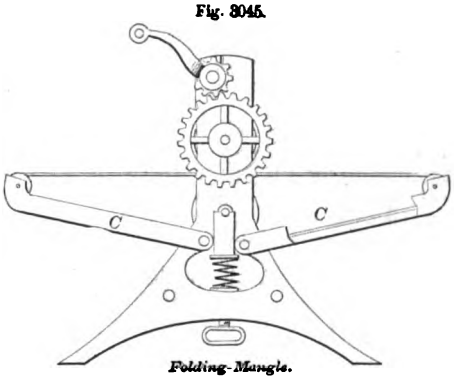
throat between the roller *B* and the first small roller.

The improved mangle for smoothing and stretching woven goods previous to starching and calendering, has a number of rollers fixed in a strong frame, and capable of being forced together by levers or screws. In some mangles, the bottom rollers have grooves diverging from the center, so as to spread the cloth outwardly towards each edge as it passes through, removing the creases. The cloth is fed to the mangle floating on the surface of water in a cistern.

Starch is applied in a somewhat similar machine, the cloth passing over a roller which dips into a starch trough, and the rollers arresting the superfluous portion as the cloth passes between them.

Fig. 3045 is a mangle in which the clothes spread upon an endless apron are passed between a pair of

Fig. 3045.



Folding-Mangle.

rollers, the upper one of which is driven and the lower one supported by springs to permit a yielding pressure. When not in use, the side pieces *C C* fold up against the standard for compact stowage.

Man'gle-rack. (*Machinery.*) A rack having teeth on opposite sides, engaged by a pinion which meshes with the opposite sides alternately. Thus the continuous rotary motion of the pinion is converted into a reciprocating motion, as in some forms of the mangle. See MANGLE-WHEEL.

Mang'ler. A machine for grinding meat, to render it more easy to masticate or to stew. A *meat-mangler*, a *masticator*.

Man'gle-wheel. This is used in mangles for pressing clothes, the object being to obtain a reciprocating, rectilinear motion of the weighted box, by means of a continuous rotary motion of the driving-pinion, to whose shaft the hand-crank is attached. As the pinion is rotated, it passes from the inside to the outside teeth of the wheel alternately, giving a reciprocating rotary motion to the wheel, which communicates a reciprocating rectilinear motion to the box. The shaft of the pinion traverses a groove in the wheel as the pinion passes from one side of the rack to the other. The pinion-shaft has a vertical movement in a straight slot in the outside bar as it makes the change from its upper to its lower position, and *vice versa*.

Fig. 3046.

Mangle-Wheel.

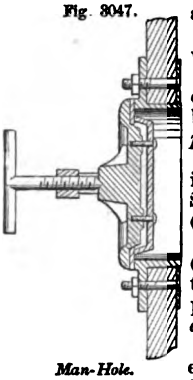
Man'helm-gold. A brass used by jewelers, as an imitation of gold. Copper, 3; zinc, 1; tin, a small quantity. See also SEMILOR; ALLOYS, JEWELERS', p. 63.

Man-hole. A hole in a cesspool, drain, iron boiler, tank, or a chamber or compartment on an iron ship, designed to allow the entrance of a man for examination, cleansing, and repairs.

In boilers and tanks it is usually secured by a bridge and bolt, so as to render it water, steam, or

Digitized by Google

Fig. 3047.



Man-Hole.

air tight, as the case may be. In drains, the cover is a lid with a stink-trap joint.

Man-hole Door. The cover or lid of a man-hole in a boiler or tank. A *man-hole plate.*

Man'i-chord. (*Music.*) An instrument resembling the SPINET and HARPSICHORD (which see).

It was originally a monochord (*single string*), and is referred to by Giraud de Calanson, a poet of Provence (*manicorda, ab una corda*).

It was played by *quills*, operated by *jacks* and *keys* on a *key-board.*

It was one of the predecessors of the piano-forte. See PIANO-FORTE.

Man'i-fold Writ'er. A device by which a number of copies may be written at once, the pressure of the stylus being communicated through a number of leaves of thin paper, between each of which is a greasy sheet of colored paper that imparts its color to the page with which it is in contact.

It was patented by Wedgwood in England in 1806. It has been much used by correspondents of the press, who thus write a number of letters to the various papers for which they cater.

Man'i-kin. An artificial figure representing the human body, and capable of being dissected to show the relative position and proportions of the parts of the body it is designed to illustrate. It is frequently of *papier-maché*, the detachable pieces being painted in imitation of the viscera and other organs.

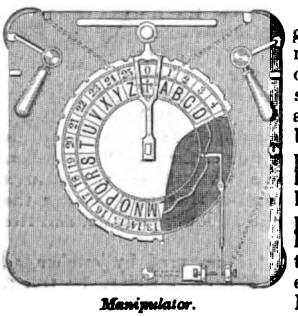
A manikin in illustration of obstetric subjects has an elastic perineum, uterus, and fetal head, so that the artificial parts may simulate the natural action of parturition.

Ma-nil'la-pa'per. Made from the fiber of a species of banana which grows in some of the East India islands. It is whiter than hemp, and the product is a stout, serviceable article. The fiber also forms cordage, sometimes known as *white rope.*

Ma-nil'la-rope. Rope made principally in the Philippine Islands, of the fibers of a species of banana.

Ma-nip'u-la-tor. The transmitting instrument attached to the dial telegraph.

Fig. 3048.



Manipulator.

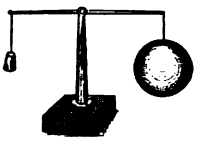
Fig. 3048, Breguet's, has a dial corresponding to that of the receiving instrument, and an arm which is turned by a handle. The periphery of the dial has a notch at each letter, into which a pin attached to the handle falls to close the circuit. This is effected by an undulate wheel within the case, which turns with the handle, alternately causing a pivoted lever to make connection with the battery and with the earth.

Man-of-war. (*Nautical.*) An armed national vessel. A *line-of-battle* ship is one of the larger classes, so as to take its place in line of battle.

Ma-nom'e-ter. An instrument for measuring the elastic force of gases or steam. It consists of a graduated tube in which a body of confined air is compressed by the gas or steam under experimental test, a body of mercury intervening between the air in the tube and the gas or steam whose elastic force is to be ascertained. The tube containing the confined air, of a certain volume at a given temperature, is maintained at the said temperature by a bath, and is tested for the graduation of the tube by means of a column of mercury. It is then ready for the connection by a tube with the reservoir or boiler which contains the gas or steam whose elastic force is to be ascertained. A *steam-gage.* See also list under CALCULATING AND MEASURING INSTRUMENTS.

Boyle's statical manometer consists of a bubble of thin glass, about the size of an orange, which, being counterpoised in an accurate pair of scales, rises and sinks with the alternations of the atmosphere. This instrument only proved a change of density, but did not detect the cause, whether arising from a change in its own weight or its temperature, or both.

Fig. 3049.



Boyle's Statical Manometer.

Ramsden's manometer, used in the Arctic researches, had a tube of small bore with a ball at the end; the barometer being sp. grav. 2.97, a small quantity of mercury was placed in the tube to prevent communication between the external air and that contained in the ball, and that part of the tube below the mercury. A scale is placed on the side of the tube, which marks the degrees of dilatation arising from the increase of heat in this state of the weight of the air, and has the same graduation as that of Fahrenheit's thermometer, the point of freezing being marked 32°. In this state it performs the duty of a thermometer; but if the air become lighter, the bubble inclosed in the ball, being less compressed, will become dilated and take up a space as much larger as the compressing force is less; therefore the changes arising from the increase of heat will be proportionally larger, and the instrument will show the differences in the density of the air arising from the changes in its weight and heat.

Ramsden found that a heat equal to that of boiling water increased the bulk of the air from what it was at the freezing-point by $\frac{414}{1000}$ of the whole. The tube being graduated for heat, under a given barometric condition, the actual indications are compared with those of a thermometer, and the difference is what is due to barometric variation from the condition at which the instrument is adjusted. Thus, the manometer and thermometer readings being given, that of the barometer may be calculated.

Man'o-scope. An instrument for exhibiting the elastic force of gases or steam. See MANOMETER.

Man-pow'er. A *man* travels, without a load, on level ground, during 8½ hours a day, at the rate of 3.7 miles an hour, or 31½ miles in a day. He can carry 111 pounds 11 miles in a day. A porter going short distances and returning unloaded carries 135 pounds 7 miles a day. He can transport in a wheelbarrow 150 pounds 10 miles a day.

The maximum power of a strong man, exerted for 2½ minutes, may be stated at 18,000 pounds raised 1 foot in a minute. — *Mr. Field's Experiments,* 1838.

A man of ordinary strength exerts a force of 30 pounds for 10 hours a day, with a velocity of 2½ feet

Digitized by Google

in a second = 4,500 pounds raised 1 foot in a minute = *one fifth* of the work of a horse.

Man-rope. (*Nautical.*) A rope which forms a substitute for hand-railing at gangways, hatchways, etc. A *ladder-rope.*

Man-ropes are also used at the bowsprit, known as *bowsprit-horses.*

Man'sard-roof. Sometimes called the *French* or *curb* roof. First designed by a celebrated French architect, François Mansard, who was born in Paris in 1598. He designed many of the public buildings in the reign of Louis Quatorze.

It was invented to make the attics available for rooms, in consequence of a municipal law limiting the hight of front walls in Paris. It is also known as a *hip*-roof. See CURB-ROOF.

Man'tel. The ornamental facing and shelf around a fireplace; hence the terms *mantel-shelf, mantel-piece, mantel-tree.* See FIREPLACE.

Man-te-let'. 1. A movable blind constructed of planks, and sometimes plated, to cover a body of pioneers and protect them from small shot. A *sap-ro'ler* is now used.

2. A protection of woven rope, etc., to protect gunners at embrasures.

Man'tel-piece. A beam across the opening of a fireplace, serving as a lintel to support the chimney-breast, or a *mantel-piece.*

Man'tel-shelf. A shelf above the facing of a fireplace. See FIREPLACE.

Man'tel-tree. The lintel of a fireplace.

Man'tle. 1. (*Founding.*) A covering of clay designed to form a matrix or mold for casting; as,

A porous clay covering of a basso-rilievo design in wax. The *mantle* and pattern are baked, the wax runs off, and the porous clay is a mold from which a casting is obtained in relief.

2. (*Building.*) *a.* The outer covering of a wall, of different material from its inner portion.

b. The enveloping masonry of a BLAST-FURNACE (which see).

3. (*Hydraulic Engineering.*) An inclosed chute which leads the water from a fore-bay to a water-wheel.

4. A cloak or wrapper.

Man'tlet. (*Fortification.*) A bullet-proof shield which is suspended in an embrasure to protect the gunners, or used as a movable shield to protect sappers in the trenches. See MANTELET.

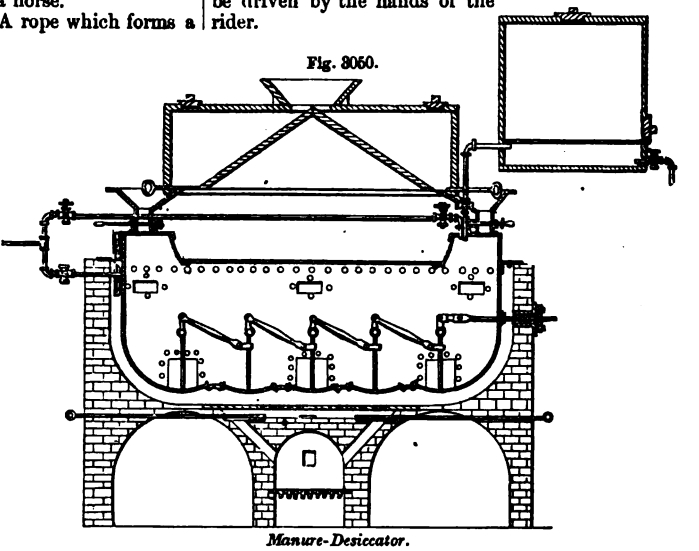
Man-trap. A trap for catching trespassers. It usually has two jaws, like a spring rat-trap, and those with smooth or toothless jaws are known as *humane* man-traps. It is not an American institution, either indigenous or imported.

Man'u-al. (*Music.*) The key-board of an organ, adapted to be operated by the hand, in contradistinction to the pedals, which are operated by the feet of the organist.

Man'u-al-key. An organ-key in the *manual*, played by the *hands;* the *pedal* keys are played by the feet.

Man'u-mo-tor. A wheeled carriage adapted to be driven by the hands of the rider.

Fig. 3050.

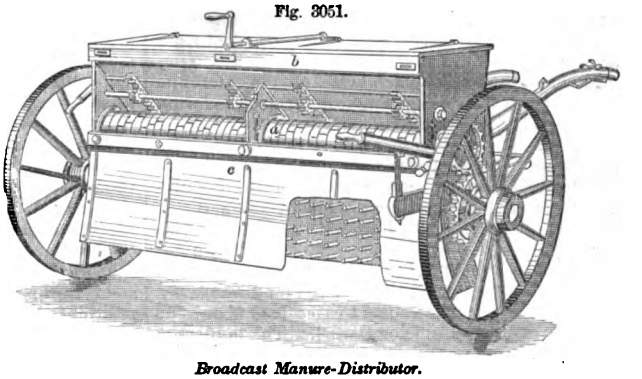


Manure-Desiccator.

Ma-nure'-des'ic-ca'tor. A furnace set within a brick chamber over which is an air-tight vessel forming a desiccating and mixing pan. Surmounting the mixing-pan is a hopper fitted with sloping bottoms provided with valves. Connected with the mixing-pan by a tube is a box provided with a false bottom, charged with some suitable absorbent, and into which the unabsorbed gases are conducted. Air is caused to circulate in the pan by means of an air-pump. The materials are stirred by oscillating paddles operated by a reciprocating rod passing through a stuffing-box.

Ma-nure'-dis-trib'u-tor. A machine (Fig. 3051) having a cylinder *a*, consisting of a series of rings with projecting surfaces, to which the manure is delivered from the box *b*. A series of scrapers below the box is arranged with springs which admit of adjustment to exert a graduated pressure on the rings, according to the quality of the manure used. The containing box *b* is provided with a stirrer, and rows of pins in the delivery-barrel *c* cause an equal distribution of the manure as it falls to the ground.

Fig. 3051.

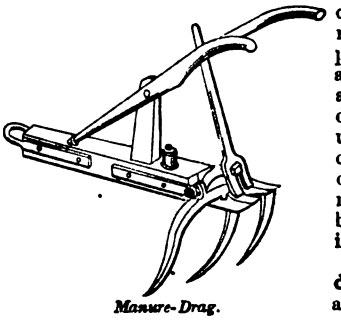


Broadcast Manure-Distributor.

Ma-nure'-drag. (*Agriculture.*) An implement drawn by a horse, and having teeth which catch into a bunch of manure, and drag it to a place where it

Digitized by Google

Fig. 3052.



Manure-Drag.

may be loaded or piled; on reaching the place the teeth are disengaged and the load dumped. Also used to scatter over the surface of a field manure which has been dumped in heaps.

Ma-nure'-drill. 1. An attachment to a grain-drill which deposits powdered fertilizer in the seed-row or broadcast, as it may be arranged.

2. A form of watering-cart to distribute in streams over the surface of a field the liquid carried in the box of the vehicle.

Ma-nure'-fork. A four-pronged fork for pitching manure, clearing stables, etc. The three-pronged dung-fork is mentioned by the Greek authors.

Ma-nure'-hook. A hand implement having three or four teeth bent at an angle with the handle, and used in dragging manure out of a stable, out of a wagon, or scattering manure-heaps in the field.

Ma-nure'-load'er. A form of horse-fork for loading into a wagon large bunches of stable manure.

Map. A representation of a portion of the earth's surface on a plane. This portion, except when Mercator's projection is used, cannot be greater than a hemisphere. There are several methods, known as "projections," employed in map-making for laying off the parallels and meridians, and locating the various positions of geographical points so as to, as far as possible, avoid relative distortion and exhibit a true likeness of the territory which the map is intended to embrace.

Anaximander of Miletus, 570 B. C., is credited with the invention of charts and maps. This is improbable, as the necessities of the Egyptians in measuring and dividing their Nile-irrigated and artificially irrigated lands must have made land-surveying and plotting a principal mode of determining the allotment of taxes. The revenue was derived from the use of water during the overflow of the Nile, and afterward of that which was stored in reservoirs during high water, — the simplest form of taxation upon property; the eminent domain of water being vested in the sovereign. The Egyptians, says Eustathius, "recorded their marches in maps."

Plate XXIX. has a representation of the popular idea of the earth in the time of Homer, 900 B. C. It consisted of a strip of land around the Pontus Pelagus, and even the boundaries were not known toward the northwest. Cimmerian darkness brooded upon the deep which surrounded the land.

Next is the world as known to Hecateus about 500 B. C., say about the time of Daniel. The borders of the Mediterranean are defined; the Iberi and Celtæ are known; the pillars of Hercules on the west and the Caspian on the east mark the longitudinal extent; back of Asia Minor is a greater Asia, which extends westward to the Nile.

In the world of Herodotus, the Caspian was changed from an indentation in the land to a lake. Asia extends to the Atlantic; Libya is a subdivision.

"Aristogoras, the tyrant of Miletus, showed to King Cleomenes of Sparta a bronze tablet, on which the whole circuit of the earth was engraved, with its seas and rivers." — HERODOTUS, V. 49.

In the geography of Democritus, 300 B. C., Europa, Asia, and Libya are acknowledged divisions.

In the maps cited by Herodotus and other geographers of his time, the grand division now known as Africa was called Libya. The term Europe is from a Semitic word *Ereb*, the *west*, *setting*, *darkness*, etc. Asia signifies the opposite, — the *east*, *rising*, etc. The origin of the term Libya is lost in obscurity. The same, except as to period, may be said of the Latin word Africa. Its derivation was a mystery 2,300 years ago.

"For my part I cannot conceive why three names, and women's names especially, should ever have been given to a tract which is in reality one, ... nor can I even say who gave the three tracts their names, or whence they took the epithets. According to the Greeks in general, Libya was so called after a certain Libya, a native woman, and Asia after the wife of Prometheus. The Lydians, however, put in a claim to the latter name, 'as being from Asius, the son of Cotys.' . . As for Europa, no one can say whether it is surrounded by the sea or not, neither is it known whence the name of Europa is derived, nor who gave it name, unless we say that Europa was so called after the Tyrian Europa, and before her time was nameless. . . However let us quit these matters. We shall ourselves continue to use the names which custom sanctions." — HEROD., IV. 45.

In former times the geographers were undecided where to draw the dividing line between Asia and Libya, as seen in the first four figures, Plate XXIX. The Egyptians were of known Asiatic origin, and it was considered more logical to include them in Asia. The eastern border of the land, abutting upon Libya, was for a time adopted. Afterwards the Tanais and the Nile were the limits of Asia, one half of Egypt being ascribed to Africa. Herodotus considered it absurd to divide the country of one people between two continents. Ptolemy, the geographer, defined the Red Sea and the Isthmus of Suez as the boundary between the continents.

Next is the map of the world according to Eratosthenes and Strabo. Eratosthenes (276–196 B. C.) of Alexandria was the discoverer of the obliquity of the ecliptic, and was the founder of geodesy. He determined the circumference of the earth by measuring a degree of the meridian. Measurements of an arc of the meridian have been made by the Chaldeans, by Eratosthenes, by Al Maimon, by Piré, and more lately by the French, English, Germans, and others; in Peru, Lapland, British India, and elsewhere. (See ARMIL; ARMILLARY-SPHERE; ASTRONOMICAL INSTRUMENTS; ODOMETER.) We regard Eratosthenes with profound respect as the author of the *science* of geography, and the name thereof. The extent of each zone he determined by the length of the solstitial day, and called them *climates*.

The "map of the world" by Hipparchus (150 B. C.) is founded on the discoveries of Eratosthenes, and is the first recorded attempt to assign geographical positions by longitudes and latitudes, obtained, the former from lunar eclipses, and the latter from lengths of the shadow measured by the gnomon.

In Strabo's time, about the Christian era, it was customary to draw a meridian and parallel for each important place whose position was considered as determined. Ptolemy, about A. D. 150, simplified the method, and probably introduced the regular plan of dividing the area by lines 5° or 10° apart, as the case might be. See cut, also "Ptolomæi Geographiæ," Roma, 1508. Congressional Library.

The maps of Eratosthenes and Ptolemy show a marked advance in geographical knowledge, especially in the bounds of Asia and Libya, the latter re-

PROGRESS OF MAPPING FROM 900 B. C. TO A. D. 1520.

PLATE XXIX. (2400 *Years.*) *See page 1186.*

Digitized by Google

Digitized by Google

ceiving in the map of Ptolemy its new name of "Africa." The old belief in a circumscribing sea is evident in the upper map, where Libya is apparently extended merely to balance the newly discovered extent of Asia, the insular character towards the south being assumed, as in the earlier maps. In the map of Democritus, the Mesopotamian rivers flow into the ocean and mark the extent of geographic knowledge, in an eastern direction, of the Mediterranean nations. In the next map these rivers debouch into the Persian Gulf; and India with its marginal rivers, the Indus and the Ganges, forms an eastern extension. Taprobane (Ceylon) is also shown. Britannia and Ierne come upon the scene with the Cassiterides or Tin Islands, which had been known to the Phœnicians for 1,000 years. There is also an indication of a land across the Baltic. It should also be mentioned here that this map of Eratosthenes was merely a plane exemplification, and that he was fully aware of the spherical form of the earth. Aristotle had said, 100 years before, that it was possible that Spain and India were only separated by the sea. Eratosthenes said that only the extent of the Atlantic Ocean prevented sailing from Spain to India along the same parallel. In the map of Ptolemy, the land grows toward sunrise, Burmah with the peninsula of Malacca comes into view, with some traces of an eastern archipelago, and a country beyond India of unknown and undefined extent; so much land in this direction, indeed, that the sea is suppressed. Taprobane is still there, but the old geographer who put upon his map the interior lakes of Africa where Livingstone found them to be, would not take the sea for granted on the southern confines of Africa more than he would on the eastern regions of Asia. Africa assumes large proportions, and the name Libya becomes local; indeed, a dotted line uniting a hypothetical eastern land with a possible extension of Africa is suggested as the termination of salt water southwardly.

Dr. Livingstone's last letter, dated from Lake Bangweolo, December, 1872, and published April 28, 1874, finishes by saying: "If the good Lord gives me strength and influence to complete my task I shall not grudge my hunger and toil. Above all, if He permits me to put a stop to the enormous evils of this inland slave-trade I shall bless His name with all my heart. The Nile sources are valuable to me only as a means of enabling me to open my mouth among men. It is this power I hope to apply to remedy the enormous evil, and join my little, helping hands in the great revolution that in His all-embracing providence He has been carrying on for ages, and is now actually helping forward."

Next we recognize the map of Cosmas of Alexandria, known as *Indico-pleustes*. His map was made about A. D. 547, and was regarded as conclusive by the Fathers of the Church. So said the doctors of Salamanca, in 1486, to Columbus, who proposed to reach the east by sailing to the west. The geographer of the Church represented the earth as a plane twice as long as it was broad, embracing the Mediterranean and indented by the Red Sea, the Persian Gulf, and the Caspian; around it was the ocean. It most resembled the map of Homer's time, 1,400 years before, and was a ridiculous burlesque in a city where Ptolemy had lived but four centuries previously. But Cyril and the monks intervening had undone in a few years the progress of ten centuries. The square shape of the land was probably in deference to the Scripture expression, "the four corners of the earth." In another view of the earth as understood by Cosmas, a vast mountain rises beyond the "Great Sea" (the Mediterranean), and when the sun emerges from behind the mountain, it is day; when he retires behind it, it is night. The circles represent the Creator looking down, the sun orient, the sun occident. The pear-shaped place half-way up the mountain is the Garden of Eden.

To come down farther in order of time, we notice the representations of the eastern and western hemispheres, as depicted on the terrestrial globe of Martin Behaim, 1492. This may be taken as representing the state of geographic knowledge out of Salamanca and the cloisters. Africa had been circumnavigated by Vasco da Gama; Asia is driven over to the eastward as far as Marco Polo is deemed to have gone in his months of weary travel. So large a proportion of the circumference of the earth was held to be embraced by the circuit of Europe and Asia, that the latter about fills the western hemisphere, the goodliest island of "Cipango" (Japan) lying off the coast of the "far Cathay." In the mid-Atlantic is the island of Antilia, a spot partly conjectural, and also the island of St. Brandan, which was purely imaginary. Thus was the globe depicted before the sailing of Columbus, and his projected voyage was not expected to be much greater than the length of the Mediterranean. He sailed and discovered what he considered to be the "Island of Antilia" (Cuba). An island under that name had appeared on the charts since 1425. Columbus was for discovering a western route to India in the interest of the Spaniards, that they might share in the rich Oriental trade then almost monopolized by the Venetians. He supposed himself to have reached the outlying islands of the Asiatic coast, and tried to worm his way among them to reach China and India. The voyage was repeated with the same intention. His third voyage carries him to the Orinoco, and the volume of water encourages a hope that the gap is found. During the next year, 1499, Vasco da Gama anchors in the Tagus with trophies from Calcutta; the Portuguese have turned the Venetian position, and the trade is their own. The western essays have yet been fruitless, for no India has been reached, and the fourth voyage of Columbus, in 1502, in which he reaches Central America, is yet barren to him, for no strait is found. Columbus died in 1506, supposing that he had discovered India, though surprised at not being able to make connection with the eastern voyagers and the land of Marco Polo's adventures. In 1500 he asserted that, "if any one does not give him credit for having discovered the remaining parts of India," it must be from personal hostility. In 1502 he writes to Pope Alexander, "I discovered 1,400 islands and 333 leagues of the coast of Asia."

Above is a representation of the western hemisphere of John Schöner's globe of 1520, fourteen years after the death of Columbus, and, no doubt, published in good faith. In it the terra-borealis forms the only trace of the North American continent, and might answer for Newfoundland. Cuba and parts of the South American continent are plotted as islands of the eastern coast of Asia, adjacent to Java major, Java minor, and Zipango, which more immediately fringed the Asiatic coast. Cuba, the Antilia of Columbus, and yet the "Queen of the Antilles," lies north and south, parallel with the coveted island of Zipango (Japan), which so persistently eluded the search of the man of Genoa, who tried to push his caravel through a continent.

Sea-charts were brought to England, 1489, by Bartholomew Columbus, to illustrate his brother's views respecting a western continent. The first tolerably accurate map of England was made by George Lilly, who died 1559.

Digitized by Google

Gerard Mercator published his Atlas in 1556. In this, as in the modern maps on the "Mercator Projection," the meridians and parallels are straight lines and cut each other at right angles.

The distance between the parallels is increased with the latitude, so as to be proportionate to the actual distance of the meridians apart.

The principles on which this projection is founded were first explained by Edward Wright, an Englishman.

It is universally employed in nautical charts.

"My Lord Barkeley wanting some maps, and Sir W. Coventry recommending the six maps of England that are bound up for the pocket, I did offer them." — PEPYS's *Diary*, 1667.

The great geographical achievements which distinguished the close of the fifteenth and the early portion of the sixteenth centuries, or the thirty years from 1492 to 1522, consist in the discovery of tropical America, the rapid determination of its form, the passage round the southern point of Africa to India, and the first circumnavigation of the globe.

The triangular form of Africa is distinctly laid down in the planisphere of Sanuto as early as 1306; in the Genoese Portulano della Medice Laurenziana of 1351, discovered by Count Baldelli; and in the map of the world by Fra Mauro. 1,700 years before this, Herodotus had characterized as incredible the statement "that those who sailed around Libya, in sailing from east to west, had the sun on their *right* hand," as in sailing eastwardly in the Mediterranean the sun at noon is always to the left. He farther states that Necho commanded the Phœnicians to make their return to Egypt by the pillars of Hercules. Strabo, while discrediting the accounts of circumnavigations previously said to have been accomplished, does not deny the possibility of the circumnavigation, but affirms that from the east to the west there was but little wanting to its completion.

Bartholomew Diaz reached and actually doubled the Cape of Good Hope in May, 1487, but, deterred by the storms, put back and reached Portugal in December of the same year, so that it was reserved for Vasco da Gama to first pass beyond the region of storms which surrounds the Cape and enter upon the waters, usually more placid, of the great Indian Ocean.

Humboldt says: "I have shown elsewhere how a knowledge of the period at which Vespucci was named 'Piloto Mayor' would alone be sufficient to refute the accusation first brought against him in 1533 by the astronomer Schöner of Nuremberg, of having astutely inserted the words 'Terra di Amerigo' in charts which he altered. The high esteem and respect which the Spanish court paid to the hydrographical and astronomical knowledge of Amerigo Vespucci are clearly manifested in the instructions which were given to him when, on the 22d of March, 1508, he was appointed 'Piloto Mayor.' But the name of 'Americi Terra' had been proposed for the new continent as early as 1507, by a person whose existence even was assuredly unknown to Vespucci, the geographer Waldseemüller (Martinus Hylacomylus) of Freiburg in the Brisgau, the director of a printing establishment at St Dié in Lorraine, in a small work entitled 'Cosmographiæ Introductio insuper quatuor Americi Vespucii Navigationes.' The map of the new continent drawn by Hylacomylus, and contained in this edition, presents the first instance of the name of 'America' in the editions of Ptolemy's Geography. It is a great error to regard the map of 1527, now in Weimar, obtained from the Ebner library at Nuremberg, and the map of 1529 of Diego Ribero, engraved by Güssfeld, as the oldest maps of the new continent. Vespucci had visited the coasts of South America in 1499 (a year after Columbus's third voyage), in the expedition of Alonso de Hojeda. He could not have had any motive in feigning a voyage in 1497, for he, as well as Columbus, was firmly persuaded until his death that his discoveries were a part of Eastern Asia. For more than 20 years after his death, which took place in 1512, and indeed until the calumnious statements of Schöner in the 'Opusculum Geographicum,' 1533, and of Servet in the Lyons edition of Ptolemy's Geography, in 1535, we find no trace of any accusation against the Florentine navigator. Columbus himself, a year before his death, speaks of Vespucci in terms of unqualified esteem; he calls him 'a very good man,' 'worthy of all confidence,' and 'always inclined to render me service.' The same good-will toward Vespucci is displayed by Fernando Colón, who wrote the Life of his father in 1535 in Seville, four years before his death, and who, with Juan Vespucci, a nephew of Amerigo's, was present at the astronomical junta of Badajoz, and at the proceedings respecting the possession of the Moluccas.

"The confusion of dates in the numerous versions of Amerigo's voyages is not to be attributed to him, as he did not himself publish any of these accounts; such mistakes and confusion of figures are, moreover, of very frequent occurrence in writings published in the sixteenth century."

The entire guiltlessness of the Florentine navigator, who never attempted to attach his name to the new continent, but the magniloquence of whose accounts unfortunately drew upon himself more of the attention of posterity than he deserved, is decisively shown by the fact that he was not even cited as a witness in the suit instituted by the fiscal authorities of Spain against the heirs of Columbus, from 1508 to 1527, with the object of withdrawing from them the rights and privileges which had been granted by the Crown to their father in 1492, in which it was to be decided what parts of the new continent were first seen by Columbus. In the course of this suit it was never pretended that he had preceded Columbus in the discovery of the continent. Amerigo died at Seville, February 22, 1512. In 1520 maps were extant, having in them the name of America, proposed by Hylacomylus in 1507.

Las Casas, in treating on the subject in an unpublished work, the "Historia General de las Indias," says that the statement that Amerigo sailed in the year 1497 appears to have been an error of the pen and not an intentional false statement, and adds that "the *foreign writers* call the country America. It ought to be Columba." Farther on he attributes intentional deceit to Amerigo, but considers it strange that Hernando Colon, who had had in his hands Amerigo's account of his travels, "remarked in them no deceit or injustice toward the Admiral."

Even Copernicus contributed to the erroneously obtained celebrity of Vespucci.

To Humboldt we are indebted for the graphic representations of complex natural phenomena by means of lines on maps, such as the isothermals, which unite places of equal mean temperature, hypsometric lines, which unite places of equal hight, etc.; or depicting, by circumscribing lines or by color, regions of equal average temperature or rainfall, population, mortality, illiteracy, wealth, race, etc. The following names are used for lines drawn upon maps to connect places of equal conditions, as follows: —

For an illustration, see Blodget's "Climatology of the United States," Philadelphia, 1857.

Isobarometric, having equal barometric pressure.

Isocheimal, having same winter temperature.

Isoclinal, indicating equal magnetic dip.

Digitized by Google

Isocrymal, having same extreme of cold.
Isodynamic, having same magnetic intensity.
Isogeothermal, passing through points beneath the surface which have the same average heat.
Isogonic, indicating equal variation of compass.
Isohyetose, having same mean annual rainfall.
Isotheral, of equal summer temperature.
Isothermal, having same mean annual temperature.
Isotherombrose, where the quantity of summer rain bears the same proportion to the annual rain.

The surveys from which the data for the construction of geographical maps on an accurate and comprehensive scale are derived embrace both geodetical and astronomical observations; the former to determine the relative positions of geographical points and their distances from each other, and the latter to fix their absolute position on the earth's surface and establish the true meridian.

The geodetical part of the work is accomplished by first measuring with extreme accuracy on the most level surface that can be selected a base line of convenient length. In extensive surveys, embracing, for instance, a whole country, this is from five to ten or more miles in length. This serves as the basis of a system of triangulation, the length of the sides of the triangles being gradually increased as they recede from the base, until they are made as long as the nature of the country or the possibility of seeing the signals erected at the various stations will admit of; this may be as much as 100 miles, or even more in mountainous countries. The area covered by these primary triangles is subdivided by smaller triangles termed secondary, and these again by a still smaller system of tertiary triangles. This work is performed with the theodolite, the size of the instruments employed being proportioned to the character of the work, from those having a circle of 2½ to 3 feet diameter for the main triangulation to those of 6 inches for the tertiary. The filling in or determination of subordinate points, the outlines of the shores of bays and other bodies of water, may be effected with instruments of an inferior class. The plane table is used for this purpose by the United States Coast Survey. The data are now transferred to paper. A scale for the map having been determined on, the projection of the lines of latitude and longitude is made, and the positions of the different points laid down on the paper with a scale and circular protractor. The topographical features of the ground, the relative levels as ascertained by leveling during the progress of the survey, and such other details as are considered advisable, are represented by a peculiar system of shading and by symbols. The map is then ready to be transferred to copper, from which any number of copies may be printed. But a very small portion of the globe comparatively has been surveyed with an accuracy even approaching that above described. Africa, Asia, with the exception of British India, South America, a large part of North America, and even a considerable portion of Europe, afford no better data for the construction of maps than detached astronomical observations at different points and rudely measured or even estimated tables of distances. Points along the sea-coast have, owing to the requirements of commerce, been generally tolerably well determined, but our knowledge of the interior geography of several of the vast continents referred to is based largely upon mere report.

Maps in relief were first produced in Germany some time in the last century. From them Haüy conceived the idea of relief-printing for the blind.

Map-hold'er. A frame for the display of maps or charts. In one form the maps are on an endless web of cloth, which is rolled off from one roller and on to another, the display being in the space between the two. A *ribbon map*.

In another form the maps are hung from separate rollers in the manner of window-shades; either is pulled down as may be desired and is re-wound by a spring.

Map-meas'ur-er. An instrument with a little wheel of known circumference, which is made to roll along a line and indicate its length, the number of revolutions being counted, and the fraction, if any, observed by reference to the pointer and graduated perimeter.

Fig. 3058.

Map-Measurer.

Mar'a-bout. A peculiar kind of silk, generally containing 3 threads, and made from the white Novi raw silk. It is dyed without discharging the gum.

Ma-ram'ba. A musical instrument of Central America, consisting of a series of calabashes of different sizes set in a frame and having the tops cut off. Pieces of parchment or membrane are stretched over the openings, and are tuned so as to produce, when beaten with an implement resembling a drum-stick, the notes of the diatonic or other musical scale.

Mar'ble. 1. A granular and crystalline carbonate of lime. In sculpture the term is applied to several varieties of stone capable of receiving a high polish.

Statuary marble is known as saccharine limestone, having a texture resembling loaf-sugar. It belongs to the metamorphic rocks; and is non-fossiliferous, having been changed by heat.

Among the ancients the Pentelican and Parian marbles, the former a pure white and the latter having a creamy or waxy tint, were most valued for statuary purposes.

In modern times the best is derived from the quarries of Carrara.

The *Potomac marble*, so called, of which the pillars of the old House of Representatives, Washington, are formed, is a *pudding-stone* or *conglomerate*. It may be described as a gravel bound together by cement.

Alabaster is no marble, but is a species of gypsum. It is a *sulphate* and not a *carbonate* of lime.

There are many fancy varieties of marble used by marble-workers; these have names derived from the geographical position of the quarries, the color, markings, geological position, etc.

White marble has a specific gravity, 2.706; weight of a cubic foot, 169 pounds; weight of a bar 1 foot long and 1 inch square, 1.17 pounds; cohesive force of a square inch, 1,811 pounds; extensibility, $\frac{1}{1364}$ of its length; is crushed by a force of 6,060 pounds upon a square inch (Rennie).

Marble for tombstones, mantels, and generally where thin pieces are required, is divided by the saw. This is a plain, narrow plate of steel, and effects the division of the stone by attrition, being constantly supplied with sand and water.

After being sawn into slabs, its surface is ground down by a flat, coarse sandstone with water, or with an iron plate fed with fine sand and water, until all the marks of the saw are removed.

It is then rubbed with a fine sandstone and water, removing the marks left by the first operation. A still finer sandstone, pumice-stone with water and snakestone are then successively employed.

The final polish is given by means of rollers of woolen cloth or list, about three inches in diameter, charged with moistened flour of emery, which is worked uniformly over every part of the surface, and

Digitized by Google

subsequently by a similar roller with putty-powder and water. Sometimes an old cotton stocking is used instead of the roller, and in some delicate works crocus is employed intermediately between the emery and putty-powder. The marble must be washed after each operation, to remove every particle of the polishing material, which would otherwise scratch the work. Turned works are similarly polished, using two or three thicknesses of cloth, held in the hand, instead of the roll. Other kinds of work, as statuary and hard varieties of marble, require a somewhat different treatment.

Rough marble is in the shape of blocks from the quarries.

Rough-hewn marble is cut with the saw or squared with the stone axe.

Outlined marble is blocked out in the rough for an architectural ornament or sculpture by the *double-point* or the chisel.

Pierced marble is worked to bring out the ornaments in relief.

Polished marble is that which has been worked by a succession of materials of gradually increasing fineness. See MARBLE-POLISHING.

Finished marble is that which is ready for its place.

2. A plate of stone used by painters. A slab on which substances are levigated by a *muller*.

3. A stone or iron plate on which glass is rolled to shape it. A *marver*.

4. A printer's imposing-stone.

5. A style of coloring, for paper and book edges. See MARBLE-PAPER.

6. Playing-marbles are made of clay, calcareous stone, marble, agate, etc. Some of stone were discovered at Pompeii.

Playing-marbles were first introduced into England from Holland, about 1650. They are made in great quantities in Germany, and constitute a not unimportant article of trade. The stone is broken into fragments, which are sorted into sizes proportioned to that of the marbles to be made. These are then ground between a lower and stationary and an upper revolving millstone to remove asperities. They are next roughly rounded by friction against each other and against two cylinders of hard stone, one of which is caused to rotate at the rate of 40 to 45 turns per minute.

The complete rounding of the marbles is effected in an oblong wooden cylinder or cask, having a double bottom, in which are one or more cylinders of hard stone. This is caused to revolve at the rate of 40 or 45 turns per minute. The dust formed during this operation is then removed and mixed with emery in pieces the size of a bean; by this the final rounding and polish are effected, in the apparatus just described.

A shining polish is obtained by revolving the marbles in wooden cylinders with fine emery.

If they are to be colored, this is done previous to their receiving the final polish, by pouring the coloring material upon them in a liquid state. They are then polished by rotation in contact with a small quantity of calcined tin-dust.

By another process the pieces of stone are rounded between a lower turning millstone and an upper stationary wooden tray, each grooved to correspond to one half the marble. A stream of water is constantly poured through an aperture in the tray, which is arranged to descend as the volume of the mass diminishes by attrition, so as to exert a constant gentle pressure. The marbles are polished between two wooden trays similarly arranged.

Clay marbles are molded and baked.

Mar'ble, Ar-ti-fi'cial. An indurated composition of gypsum, alum, isinglass, and coloring materials incorporated into a paste and molded into form.

In Mellen's patent, 1872, any of the hydraulic or marble cements may be used. The cement is mixed with the colors, each color separately to a consistence which will admit of its being poured from a vessel having a spout.

The mixture is poured from the vessels in small streams upon a smooth surface of glass, wood, metal, or plaster of paris, so as to imitate the veins in any particular kind of marble, the interspaces being filled in with a mixture of cement and color corresponding to the color of the body of the stone. A wind-blast, produced by bellows or otherwise, is employed to make the colors flow, so as to produce the mottled appearance of marble.

For producing delicate veins, threads of silk or other material are dipped in the desired color and laid upon the smooth surface; these are drawn out after the cement has been poured on. The cement absorbs the color from the thread, exhibiting a fine streak of the desired appearance. After the various colors have been laid on the smooth surface, the back is smoothed over and strengthened by a backing of cement, pieces of metal being employed to bind the two together and impart firmness to the slab.

The process of Pichler of Vienna is recommended for plastic decorations of all kinds: Take one pound of good glue and boil it down so that it will be quite thick; add then half a pound of resin, or, better still, Venice turpentine, and mix well. Prepare a mixture of fine chalk and such mineral colors, finely pulverized, as are required for certain imitations. The less the ingredients are mixed, the better will be the imitation. The paste formed by blending the two mixtures is then kneaded until of the proper consistence. A few drops of oil may be added to it. This mass can be immediately used, and becomes hard like stone. If desired to be kept for a while, it is only necessary to wrap it in a moist cloth.

Mar'ble-cem'ent. A composition of gum-lac, colored to suit the occasion.

The rust cement is also used, composed of hydrochlorate of ammonia, 2; flour of sulphur, 1; iron filings, 16.

For coating insides of cisterns, pulverized baked bricks, 2; quicklime, 2; wood-ashes, 2; olive-oil to make a paste.

For stone seams and joints: pulverized tiles or hard brick, 6; white-lead, 1; litharge, 1; oil to compound.

Hydraulic cement, 12; triturated chalk, 6; fine sand, 6; infusorial earth, 1; all mixed with soluble soda glass.

Mar'ble-cut'ting Ma-chine'. A machine for cutting marble in the quarry. A *channeling* machine, which cuts deep grooves in parallel lines. This is sometimes done by the impact of a gang of stamping-chisels, but in the example is effected by a chain-saw whose links are armed with diamonds. The diamonds are held in the ends of split screw-bolts or clamps, which are tapered and forced into tapering cavities, causing them to contract upon the diamonds. The diamonds are applied on the edge of a rotating disk, or the links of an endless chain, and the supporting standard of the disk or chain is so connected to the driving mechanism that it may have feed in any direction.

The chain-saws are carried by wheels *w w'*, which are driven by shafting from the steam-engine on the truck, whose proper motion feeds the saws to their work. Devices are afforded for changing of the saws to vary the direction of cut. The lower right-hand figure shows the mode of presentation of the diamond-chain for making a horizontal under-cut.

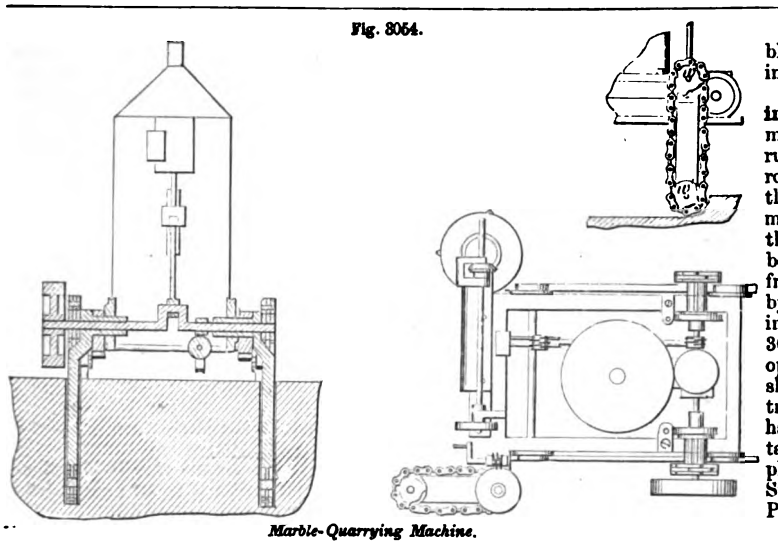
Fig. 3054.



Marble-Quarrying Machine.

Mar'ble-edge. (*Bookbinding.*) A mode of ornamenting the edges of bound books. The process is described under MARBLE-PAPER (which see).

Mar'ble-fin'ish-ing Ma-chine'. One for truing and molding the edges of marble slabs for mantels, tables, etc. The molding-tools, having a contour the converse of the molding required, are keyed on the top of vertical, revolving mandrels *t t*, which are adjusted vertically by the hand-wheels *o' o'*, which traverse on the screws *q q*.

The feeding-tables at each side of the machine present the marble in the required line of motion to the revolving-tool. The cutting-tools are changed as the work progresses, some having perforations to supply abrading material.

The feeding-table is susceptible of two motions, one tangential to the circle described by the revolving-tool, and the other at right angles to that of the first.

The right-hand table has a block clamped in position.

Mar'ble-grind'-ing Ma-chine'. A machine in which the rubber-stone is reciprocated or rotated over the marble slab by mechanical means. In the example, the rubber is attached to the free end of the pitman by means of connecting-forks *i i* (Fig. 3056). Other machines operate upon a series of slabs laid in an annular trough, the rubbers having a combined rotary and revolving, or planetary motion. See STONE GRINDING AND POLISHING.

Mar'ble Hand-saw. A blade without teeth, and having a block handle at the back. It is used with sand for cutting slabs into pieces or slips.

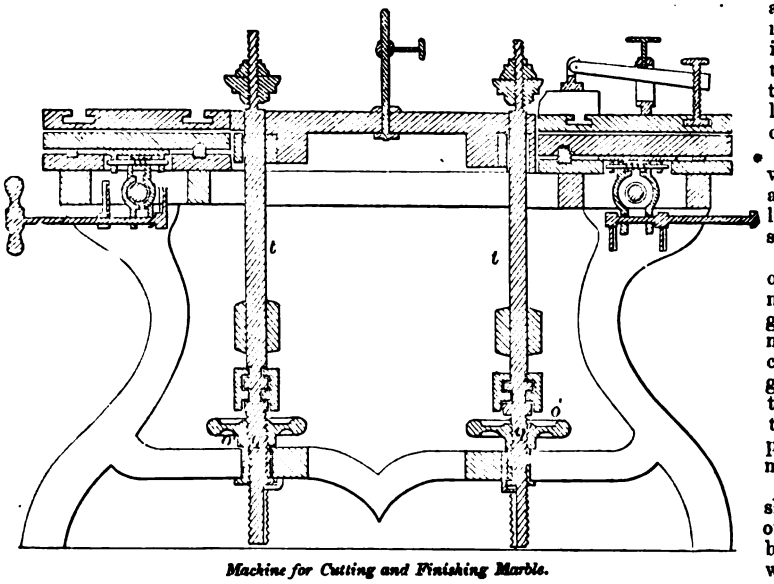
Mar'ble-is-ing Slate. Coloring its surface in imitation of variegated marble.

The slab is rubbed with pumice, and then polished with pulverized pumice and afterward with felt. It is then painted with the groundwork color, and its surface dipped in a vat containing water, on which oil-colors have been sprinkled, manipulated with a brush and subjected to a fanning process, in order to cause a variegated appearance.

Imitations of various kinds of marble are produced by an appropriate application of the different colors. Successive bakings and polishings complete the process.

Mar'ble-pa'per. Paper ornamented with a colored pattern resembling marble; or ornamented by the same process with patterns bearing no analogy to those of marble, but assuming certain conventional forms, in which the colors are singularly blended and contrasted.

Fig. 3055.



Machine for Cutting and Finishing Marble.

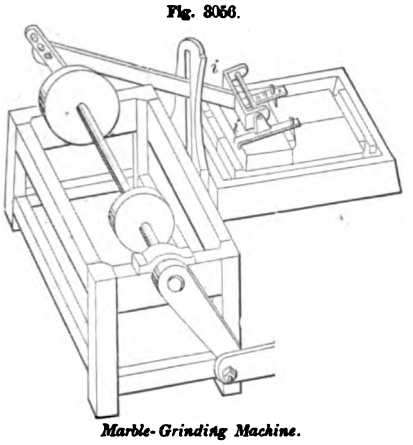
The process was invented in Germany about 1620, but was long maintained a secret.

The pulverized colors in a dry state are mixed with water and ground in a paint-mill, after which the chemicals used for giving them consistency are added, and the whole again passed through the mill.

Mineral colors only should be used, those of vegetable origin being apt to fade when exposed to the

Digitized by Google

Fig. 3056.



Marble-Grinding Machine.

light. For use, they are thinned with water and placed in wide-mouthed jars. The brushes ordinarily used for sprinkling the colors are small sash tools, the hairs of which are spread out into a circular form by driving a small nail with a leathern washer into the center of the handle.

A mucilage of gum, usually tragacanth or *gum-ogg*, is prepared, about the thickness of sweet-oil. This is placed in a trough, and the colors which are to form the pattern are sprinkled one at a time over its surface, those forming the veins first and that for the groundwork last. The paper, on a table to the left of the workman, is taken up, sheet by sheet, by the extreme corners, bent in the form of a bow, and gradually let fall on the composition in the trough. The colors, which float on the surface, and a portion of the mucilage, adhere to the paper, which is then taken up and hung on racks to drip, the color remaining and the mucilage falling into a trough below the rack.

The paper when dry is glazed by means of a piece of polished flint, semicircular in section, set in a block of wood, into the opposite side of which is inserted a pole 5 or 6 feet long, the upper end of which fits loosely in a groove in a spring-board above. The paper is laid on a grooved block, having a very smooth surface, secured to a strong wooden table; and the operator, using his right hand to propel the pole and his left to guide the paper, moves the flint-polisher back and forth over its surface, which operation, aided by the pressure of the spring-board on the end of the pole, effectually glazes the paper.

This primitive mode of glazing is now generally superseded by the process of calendering between two rollers of polished steel, which effects the result in a more perfect, durable, and rapid manner.

The edges of books may be marbled in a similar way. For this purpose a mucilage of linseed, allowed to simmer at a gentle heat for five or six hours, may be used instead of the more expensive gums.

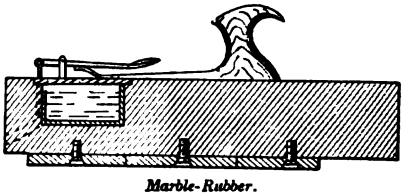
The varieties are thus cited by Cooley (Practical Recipes, page 753): *soap*, *thread*, *rice*, *tree*, *wax* marbling, according to the style of associating the colors, placing them on the mucilage, the use of combs, threads, etc., to dispose the colors, and the choice of materials.

Mar'ble-pol'ish-er. Marble is first rubbed with sandstone, and the beater, afterwards with pumice-stone. It is polished by hand with a linen cushion and emery-dust for colored marbles, and with the powder of calcined tin for white marbles, the emery being apt to redden them.

In Italy a piece of lead is used instead of linen.

A *rubbing-block* is used for carrying the grit or powder for grinding, surfacing, or polishing the faces of marble slabs. In the example, the polishing material of pulverized flint and gum-shellac is carried in a cistern in the rubber-block, and is allowed to es-

Fig. 3057.



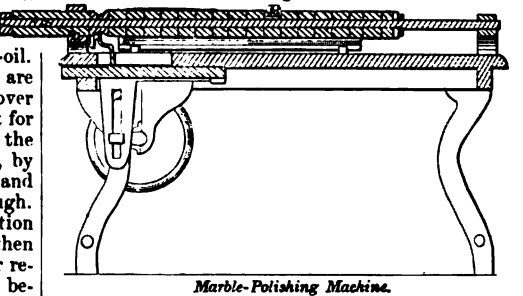
Marble-Rubber.

cape at a hole in front of the block when the gate is raised by touching the trigger.

In Maloy's patent, the marble slab is placed on the slide and its edge polished by an endless belt, which is tightened by an adjustable idler.

In this machine, Fig. 3058, the grinding-cylinder

Fig. 3058.



Marble-Polishing Machine.

B is made up of a number of collars slipped on to a mandrel. It is rotated and at the same time receives an endwise motion or a longitudinally reciprocating and intermittingly rotating motion above the table on which the slab of marble is placed.

Mar'ble-re-lief' Work. One mode of making relief-work in marble is by painting the required ornament with varnish upon the surface of the marble, and then subjecting the exposed surface to acid. A mixture of hydrochloric and acetic acids has been used.

The varnish may be a solution of gum-lac in alcohol or the *ground* of the engraver, a resinous compound dissolved in turpentine.

This recipe is from the *Dictionnaire Encyclopédique*, 1785.

Mar'ble-rub'ber. A block or tray with a flat sole, moved above the marble slab with a combined rotary and reciprocating motion. In the example, the tray has vertical slots to allow the passage of water and sand, and a socket to receive a spindle to which the handle is attached, and which supports the water-vessel.

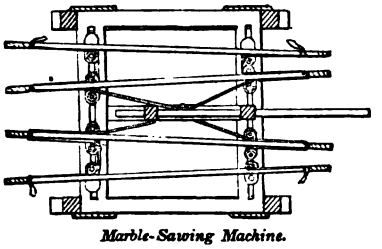
the example (Fig. 3060) the saw is operated by pitmans and eccentrics.

Fig. 3061 is a plan view of a machine in which the saws may be adjusted to saw a block into pyramidal forms. Guide-blocks, provided with rollers over which the belts pass, are secured within

Fig. 3061.

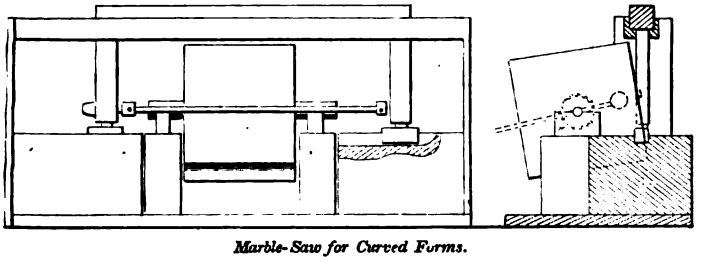


Marble-Sawing Machine.

slots on each side of the saw-frame, by which the saws are adjusted to operate at various angles and at different distances from each other.

Fig. 3062 is a machine in which the block is adjusted on centers and rotated against the saw, so as to cut the block into a cylinder or a conical frustum. The rod or wire saw has a triangular cross-section.

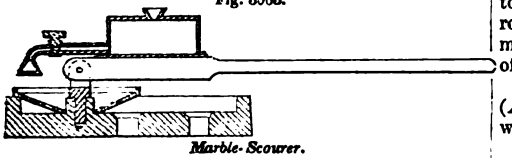
Fig. 3062.



Marble-Saw for Curved Forms.

Mar'ble-scour'er. A rubber for surfacing marble slabs. The metallic block has a handle by which it is moved backward and forward over the marble

Fig. 3063.



Marble-Scourer.

floor to be scoured. Sand is carried in the recessed top, which has holes communicating with the lower face. A box on the handle contains water, which is supplied to the working-face through a faucet and rose nozzle.

Mar'ble-work'er's Files. The files and rasps (*m n o p*, Fig. 3032) of the marble-worker and sculptor are of various shapes and grades of fineness. Hiram Powers's *perforated file* has holes to allow the escape of the dust. See STONE-CUTTER'S TOOLS.

Mar'bling. In the ordinary method of marbling book-edges, a trough about two inches deep is filled with a solution of gum-senegal water. Various coloring matters, ground in spirits of wine and mixed with a small quantity of ox-gall, are thrown upon the surface of the water and disposed in the pattern desired by means of a quill and comb. The book is now tied between two boards, and the edges being dipped into the trough the colors become attached; the workman blows away the excess of gum and allows the colors to dry. They are afterward burnished. See MARBLE-PAPER.

March. (*Weaving.*) One of the short laths laid across the treadles under the shafts.

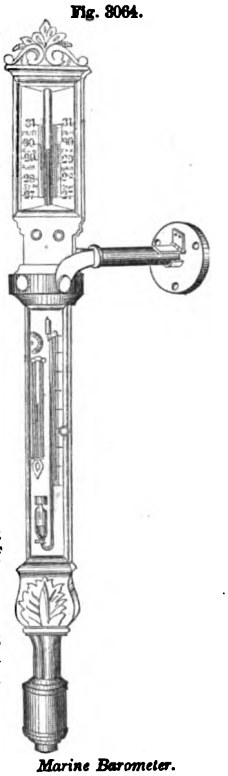
Mar'cus. A large iron-headed hammer.

Mar'gin. 1. (*Roofing.*) The exposed portion of a slate, tile, shingle, or clapboard, when secured on the roof. The width of the margin is the *gage*. The hidden portion is the *cover*. The amount which the slate or shingle of the second course above overlaps a given course is the *bond* or *lap*. Thus, —

A shingle 18 inches long and 6 inches exposed to the weather has a *gage* of 6 inches, a *cover* of 12 inches, a *bond* of 6 inches.

A slate 27 inches in length and a *gage* of 1 foot will have a *bond* of 3 inches.

Fig. 3064.



Marine Barometer.

2. (*Carpentry.*) The flat part of the stile and rail of framed work; such as panel-doors. A *lock-rail*.

Mar'gin-draft. (*Masonry.*) A plain surface adjacent to the joints of ashlar, surrounding the pick or hammer dressed middle portion of the face.

Mar'i-gold-win'dow. (*Architecture.*) A catherine-wheel window.

Mar'i-graph. An apparatus for registering the hight of the tides. A *tide-gage*.

Ma-rine' A-larm'. See BILGE-WATER ALARM; FOG-ALARM. See also list under ALARM.

ed in gimbals, and attached by an arm to some upright fixture of the ship, enabling it to maintain a vertical position during the rolling and pitching motions of the vessel.

Ma-rine' Boil'er. One adapted for the use of steam-engines on sea-going vessels. See MARINE STEAM-BOILER.

Ma-rine' Car. A floating vessel with a platform supported upon flotative revolving drums and propelled by a paddle.

Ma-rine' En'gine. A steam-engine to propel a sea-going ship. There are various kinds of them: the beam, direct-acting, oscillating, trunk, high-pressure, etc. See p. 1399.

Ma-rine' Glue. A composition of caoutchouc, shellac, and mineral oil.

Ma-rine' Gov'ern-or. A governor for marine engines, intended to overcome the effects of the motion of a vessel on a governor of ordinary construction.

Silver's marine governor (American), in use in the British navy, is shown in Fig. 3066. It was patented in the United States, October 2, 1866. A somewhat similar governor was patented in England by Mr. Silver, May 23, 1857, and in the United States April 26, 1859, and reissued to him July 25, 1865.

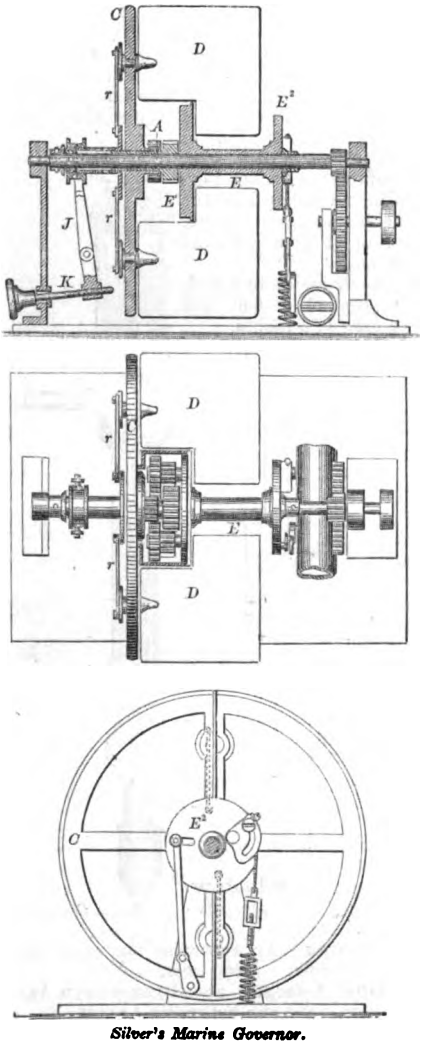
In the form shown, the governor consists of a momentum or fly wheel *C*, revolving loosely on the shaft *A*. The fly-wheel carries vanes or fans *D D*, which may be adjusted to present a greater or less surface of resistance to the air, by means of the screw *K* and levers *J r r*. The sleeve *E* and its collar *E'* also rotate loosely upon the axis *A*, and parallel with the fly-wheel. This sleeve is drawn backward against the motion of the fly-wheel by a spring, which has a tendency at all times to open the throttle-valve. The tension of the spring is regulated by an eccentric segment bolted to the collar E^2 of the sleeve *E*.

The collar *E'* bears two gear-wheels on pins in its face extending toward the fly-wheel, which gear with a fixed wheel on the shaft *A*, and again, at a different speed, with a gear on the fly-wheel.

The vanes are set and gearing adjusted so that the fly-wheel will maintain a nearly uniform velocity. When the driving-shaft exceeds its normal rate of speed, the collar *E'* is carried forward relatively to the fly-wheel, and instantly closes the throttle-valve. A slackening of speed of the driving-shaft permits the spring to turn the sleeve in a contrary direction and open the valve, — the fly-wheel remaining all the time the unit of motion, and maintaining a nearly uniform speed, due to its momentum, the variable pressure of its fans, and its free attachment to the driving-shaft.

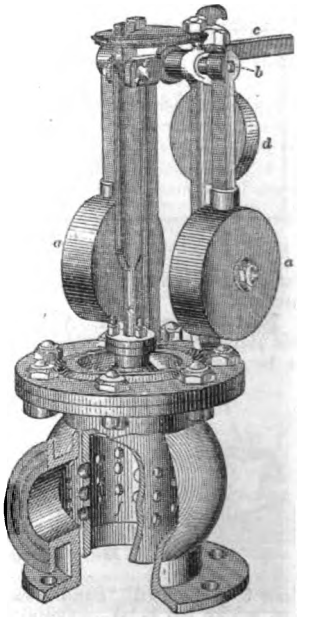
Osborne's marine governor operates by the force of a volume of mercury or other heavy, viscid fluid in a revolving vessel, acting upon a number of vanes held in position against a current of a given force by a spring. Any increase in the speed

Fig. 3066.



Silver's Marine Governor.

Fig. 3067.



Cathcart's Marine Governor.

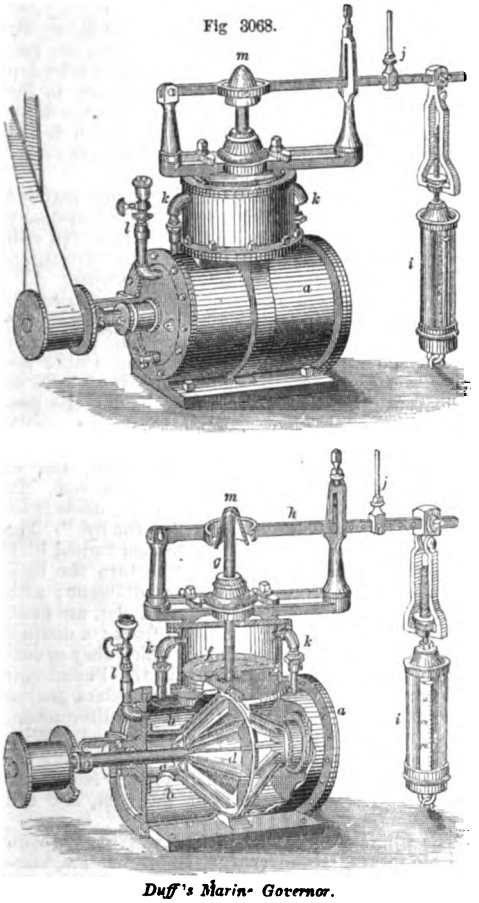
Digitized by Google

of the revolving vessel beyond its normal rate overcomes the force of the spring, turns the vanes, and closes the throttle-valve by a mechanical connection. *Per contra*, if the revolving vessel moves slower, due to a slackening of speed of the engine, the spring overcomes the vortex in the vessel and opens the valve.

Cathcart's marine governor is designed for screw-propellers, to prevent racing of the screw when the ship pitches. It is constructed with pendulous weighted arms *a a* depending from a rock-shaft *b*, on which is keyed a beam *c*, carrying at one end an adjustable counterbalance *d*, and connected at the other end by a rod *e* with a sliding-valve *f*, or a throttle of any form. As the arms *a* swing forward by the pitching of the vessel, the throttle-valve is partially closed, and by this means passage of steam is regulated in proportion to the immersion of the screw.

Duff's marine governor (Fig. 3068) operates by the

Fig 3068.



Duff's Marine Governor.

force of a centrifugal pump in a vessel of oil. *a* is the exterior case, inclosing chambers *b b*, from which passages *c* lead to an inner chamber. In this chamber there is a centrifugal wheel *d*. The chamber in which this wheel revolves communicates with a piston-cylinder by means of an annular passage *e*. *f* is a piston which raises a stem *g*. Through this stem downward pressure is transmitted to the piston from the lever *h*, which is pressed downward by a spring-balance *i*. Through the rod *j* power is taken off to control the throttle-valve or cut-off valve-gear. Pipes *k* form the communication between the space above the piston and the chamber *b*. Through the pipe *l* oil is put into the outer chamber *b*. The lever *h* transmits its pressure to the stem *g* by means of a pivoted conical cap *m*.

The centrifugal wheel *d* being put in motion by a belt from the engine, the oil in the outer chamber passes in through passages *c* to the inner chamber, whence it is forced through the annular passage into the cylinder under the piston. The pressure on the piston depends upon the speed of the centrifugal wheel, which is much higher than that of the engine, and therefore much more sensitive to change in velocity.

In another governor for marine engines steam in regulated quantity is admitted to an auxiliary regulator-engine, whose rate is therefore constant. This engine is connected by mechanism with the main engine, so that discrepancies in rate will affect the admission of steam to the main engine. — *London Engineer*, Vol. VIII. p. 347.

The chronometric governor is one which has also been adapted to this purpose. In it a time-measurer, such as a clock, is set to work at a prescribed rate, and is so connected to some moving portion that any discrepancy in the respective rates shall act upon a third portion whose motion is communicated to the throttle. Mosman's is of this character: one of two shafts is regulated by a balance-wheel, and the other has motion directly from the engine. A variation in rate of motion causes a longitudinal motion of the shaft which is connected to the governor-valve.

The electro-magnetic marine-governor of Captain Wolcott, U. S. A., is intended to prevent the racing of the screw when the propeller rides out of water when the vessel pitches. The throttle-valve is under the command of a weight when a detent is removed by an armature on the breaking of an electric circuit. The poles of a pair of wires are conducted aft to a point, say a little above the level of the screw, and, when they are submerged, the electric circuit is complete through the water. When the vessel pitches and the poles ride out of the water the circuit is broken, the armature drops away from the magnets, the detent of the weight-pulley is released, and the throttle-valve is closed. When the poles of the wires again dip into the water, the armature closes and the valve is again opened.

Ma-rine' Rail'way. One on which a vessel is hauled up for repairs.

Mar'i-ner's Com'pass. The mariner's compass has a magnetized bar of steel, called the *needle*, having at its center a cap which is supported upon the sharp point of a pivot-post. To the needle is attached a circular card with the cardinal points and minor divisions marked upon it; the number of *points* or *rhumbs* being 32, and these being subdivided into *half* and *quarter points*. A point is 11° 15′, and outside the circle of points is a circle of degrees.

The pivot rises from the center of a box called the *compass-box*, and this is hung by *gimbals* in the *binnacle*, so that the box may always retain a horizontal position, notwithstanding the pitching and rolling of the vessel. The *needle*, the *card*, *rhumb-card*, *compass-card*, or *fly*, is free to float around according to its magnetic impulse, and a mark on the front side of the circumscribing ring shows the direction of the ship's head. The *dab* is the socket of the needle on the pivotal pin.

A is a vertical central section of the compass, as hung in gimbals.

B is a view looking down upon the same.

C is a chart showing the compass notation. The

Digitized by Google

marks are known as cardinals, N. S. E. W., and intervening are the other 28 points.

D is the Chinese compass-card.

The needle of the Chinese compass is very short and light, not exceeding an inch in length, and so much of its weight is below the point of suspension, that it is but little affected by the *dip* or inclination. The means of suspension is a steel point rising from the bottom of the wooden compass-box and entering a hemispherical copper cup attached by copper strips to the needle.

Fig. 3069.

Mariner's Compass.

Sir George Staunton, who accompanied Lord Macartney in his embassy to China, describes it in his account of the embassy: "Upon the upper surface of the box are drawn several concentric circles, distinguished by different Chinese characters. The eight marks on the inner circle mark the cardinal points, south, north, east, west, and the bisecting intermediate points. The same eight characters also signify equal divisions of the natural day, so that the instrument answers to some extent the purpose of a dial, each division marking three hours. The Chinese character for *sunrise* is the same as that for *east*, and in this form was the first compass which found its way to Europe in the beginning of the fourteenth century. Other circles have 12 and 24 divisions, with characters which mark corresponding portions of the heavens and of the natural day. Each of the latter portions embraces 15° of the 360° into which the circle has been arbitrarily divided in correspondence with the supposed number of days in which the sun performs his apparent course. The remaining circles around the compass contain the characters of the cycle of 60 years, by which this nation regulates its chronology, and other characters expressive of their philosophical and mythological doctrines. The ornamented end of the needle is the south pole, to which this nation gives the preeminence. *South* and *north*." The compass is known as the *Ting-nan-ching*, or "needle pointing to the south." The Chinese were acquainted with the declination of the needle, and were aware that it is not the same in all countries nor invariable in the same place.

The Chinese compass is probably the first portable time-indicator; not absolutely accurate, especially in the different latitudes of that country, but still possessing value as an approximation to correctness.

The mariner's compass originated in China.

The Chinese word *Tchi-nan* (*the southern pointer*), indicates the Chinese practice of considering the *south* the principal cardinal point. The Emperor's throne and all government edifices in China are made to face the south, and the needle is said to point south and north, the former having the preeminence in expression.

Among the Chinese, Thibetans, and Mongolians the *south* is mentioned before the *north*, and in Chinese and Mongolian the *west* before the *east*. In Mongolian the word *south* means *front*, *north* is *behind*, *west* "to the *right*," *east* "to the *left*." The Chinese character for *north* is two men turned back to back, and originally meant "to turn the back upon." The Hebrew practice was different; with them the words *before*, *behind*, *right*, *left*, are used, but the *east*, the rising sun, is in front; a distinct trace of the Baal (sun) worship to which they so constantly recurred, in sympathy with the Phœnicians and Canaanites. "The sea" was sometimes used as a term for the west, meaning the Mediterranean, which was behind when the sun was faced. With us, the north is supposed to be faced in giving the points of the compass in their order; *boxing the compass*. The Hawaiians front the west, and call north *right*, south *left*.

The Chinese chronicles of Szuki of Szumathsin, written in the second century before our era, state that 900 years before, Tsching-wang, the Emperor of China, gave "*magnetic cars*" to the ambassadors of Tonquin and Cochin China, in order that they might "not miss their way on their return home."

In the forward part of the magnetic car was a floating needle, the motions of which were communicated to a small figure whose outstretched arm and hand pointed toward the south. It was used as late as the fifteenth century A. D., and the cars, carefully preserved in the imperial palace of China, were used in determining the point toward which the main sides of the public buildings should be directed.

It thus appears that the compass was first used by

Digitized by Google

land travelers, which, as Humboldt remarks, is a singular fact. It was, however, used on board vessels in the Chinese seas in the fourth century A. D. and probably much earlier. The effect of the loadstone on iron is noticed in a Chinese dictionary, A. D. 121; and another work states that "fortune-tellers rub the point of a needle with a loadstone to give it the power of indicating the south." The Japanese say that at a time corresponding to A. D. 543, the "wheel which shows the south" was sent to the Mikado from the court of Petsi in Corea.

From China to India was in the natural order of trade, a route which has been followed by many arts, such as the glazing of tiles and pottery, the manufacture of sonorous bronze, gunpowder, etc. When Mahmoud of Ghazni invaded India, several arts were scattered abroad and found their way still farther to the westward; the immediate introducers into the countries bordering on the Mediterranean being the Arabs, whom many have credited with the invention of arts which they derived from the farther East. The Arabic designations of *Zoron* and *Aphron* (south and north), which Vincent of Beauvais gives to the two ends of the magnetic needle, indicate the source whence the compass was directly obtained; and the influence of this people in the science of astronomy is also indicated in the Arabic names of many stars which are still retained.

"The dwellers in the West received, through the Macedonian settlements, accurate accounts of Indian productions of nature and of art, of which little more than the names were previously known by reports derived either through more ancient commercial connections, or through Ctesias of Cnidos, who had lived for seventeen years at the Persian court as the representative of Artaxerxes Mnemon. Such were the watered rice-fields, of the cultivation of which Aristobolus gave a particular account; the cotton-shrub, and the fine tissues and paper for which it furnished the materials; spices and opium; wine made from rice, and from the juice of palms, the Sanscrit name of which, *tala*, has been preserved by Arrian; sugar from the sugar-cane, which, indeed, is often confounded by the Greek and Roman writers with the *tabaschir* of bamboo stems; wool from the great Bombax trees; shawls from the wool of the Thibetian goat; silken (*Seric*) tissues; oil of white Sesamum (Sanscrit, *tila*); oil of roses and other perfumes; lac (Sanscrit, *lakscha*, and in the vulgar tongue, *lakkha*); and, lastly, the hardened Indian *wootz* steel." — HUMBOLDT.

During or before the twelfth century A. D., the mode of suspending the needle had been improved in China, by hanging it upon a silken thread instead of floating it on water. At this period the Chinese philosopher, Keon-tsoung-chi, observed the variation of the needle, which was again noticed by Columbus in 1492, and by Sebastian Cabot in 1540. The Chinaman says: —

"A point of iron touched by the loadstone receives the power of indicating the south; still it declines towards the east, and does not point exactly towards the south."

French observations at Pekin confirm this, only stating it to be a variation from the north of 2° to 2° 30′ to the west; while the Chinese, insisting on their mode of stating it, set it down as being from 2° to 2° 30′ to the east.

Columbus first noted a line of no variation about 100 miles west of the Azores.

It is a remarkable fact that the earliest European writer on terrestrial magnetism, William Gilbert, whom we cannot suppose to have had any knowledge of Chinese literature, regards the mariner's compass as a Chinese invention which had been brought to Europe by Marco Polo.

The compass of the Phœnicians is believed to have been a needle buoyed by a slip of pith and floating in a cup. That of the Arabs was described in 1242 by the Arabian Boulak Kibdjaki.

"Among the properties of the magnet, it is to be noticed that the captains who sail in the Syrian waters, when the night is dark, take a vessel of water, which they shelter from the wind, upon which they place a needle buried in the pith of a reed, and which thus floats upon the water. They then take a (*magnes*) loadstone as big as the palm of the hand, or even smaller; they hold it near the surface of the water, giving it a rotary motion until the needle turns upon the water; they then withdraw the stone suddenly, when the needle with its two ends points north and south. I saw this with my own eyes on my voyage from Tripoli in Syria to Alexandria in the year 640 [640 of the Hegira, 1240 A. D.]. I heard it said that the captains in the Indian seas substitute for the needle and reed a hollow iron fish, so magnetized that when placed in the water it points to the north with its head and to the south with its tail. The reason that the fish swims, not sinks, is that metallic bodies, even the heaviest, float when hollow and when they displace a quantity of water greater than their own weight."

Worthy Arabian; we have here a description of a magneto-electric needle used in the Levant; a magnetized floating needle used in the Indian Ocean; and a correct statement of the Archimedean discovery of specific gravities. This was written about the time of Roger Bacon, 250 years before Da Vinci, 350 years before Porta, and more than 400 years before Galileo and Newton.

The Phœnicians circumnavigated Africa in the seventh century B. C., as we learn from Herodotus.

Strabo (writing about A. D. 18) says: —

"If the extent of the Atlantic Ocean were not an obstacle, we might easily pass by sea from Iberia [Spain] to India, still keeping in the same parallel."

So Christopher Colon reasoned. See MAP.

It thus appears that the Arab needle had only temporary polarity, and this was probably the case with the Phœnician. It was consulted by the captain, and not kept in a binnacle like the Chinese and the modern needle.

Hercules, the symbol of Phœnician enterprise, in his colossal statue at Tarentum, referred to by Pliny, is represented with a key in one hand and a bowl in the other. The cup he is fabled to have received from Apollo, and in it he floated his polarized needle.

The name of Hercules is given to the stone *magnes*. The needle is probably the "arrow of Abaris." This supposition adds interest to this ancient classical symbol.

In 1190, Guyot of Provence wrote a satirical poem, called "La Bible," in which he refers to the use of the magnetic needle.

Between 1204 and 1215, Jacobus of Vitry, Bishop of Ptolemais, referred to it in his description of Palestine, as follows: —

"The loadstone is found in India, to which, from some unknown cause, iron spontaneously attaches itself. When an iron needle is touched by the stone, it at once points towards the North Star; from whence it has become useful to those who navigate the seas."

Latini of Florence, the preceptor of Dante, in a work published in Paris in 1260, entitled the "Treasure," wrote thus: —

"When I was in England, Friar Bacon showed me a magnet, — an ugly black stone to which iron doth willingly cling. You rub a needle upon it;

Digitized by Google

the which needle, being placed upon a point, remains suspended and turns against the star, even though the night be stormy and neither star nor moon be seen; and thus the mariner is guided on his way."

The Italian Riccioli, in his work upon Geography and Hydrography, states that before 1270 the French mariners used "a magnetized needle, which they kept floating in a small vessel of water supported on two tubes so as not to sink."

The magnetic needle is mentioned by Peter Adsiger in a Latin essay in 1269, in which the south pole is said to vary a little to the west; and by Raymond Lully of Majorca, in his "Fenix de las Maravillas del Orbe," published in 1286.

A passage in the Spanish "Leyes de las Partidas" of the middle of the thirteenth century runs as follows: "The needle which guides the mariner in the dark night, and shows him how to direct his course both in good and bad weather, is the intermediary between the loadstone and the North Star."

Dante, about 1300, refers to the needle "which points to the star."

Marco Polo, the great traveler, was in the service of Kublai Khan, the conqueror of China, from 1274 to 1291, and was concerned in the introduction of the compass from China to Europe direct. It had previously arrived by the good old channel, India and Arabia; but Marco Polo did not know that, and his services can hardly be exaggerated.

The Arabs sailed by the compass during the Khalifate of Cordova, which lasted till A. D. 1237, when it was subdued by the Moors. An authority states that it was known in Norway previous to 1266.

Dr. Gilbert, physician to Queen Elizabeth, states that P. Venutus brought a compass direct from China in 1260.

See Klaproth's work on this subject, Paris, 1834; Sir Snow Harris's "Rudimentary Magnetism"; the researches of Biot, Stanislaus Julien, etc.

About 1320, Flavio Gioja, a pilot of Positano, not far from Amalfi in the Kingdom of Naples, was instrumental in the improvement of the compass, and for a time passed as the inventor thereof. Such a claim is fully disposed of by the facts above cited.

It is probable that Gioja was a skillful mechanic, and improved upon the popular modes of supporting the needle (which were by floating it, or suspending it by a cord), and placed it upon a pivot-post in the center of a marginal strip, which was marked with the cardinal points and minor divisions. This rendered it more convenient for reading, and gave a certain steadiness to the needle.

Vasco da Gama, who circumnavigated Africa, doubling the Cape of Good Hope, November 20, 1497, testifies his surprise at meeting in the Indian Ocean seven small Arab vessels provided with the compass, quadrants, sea-charts, and other instruments, equal to the Portuguese. We do not wonder, for the China seas had been navigated by their aid over 1,000 years when the brave navigator repeated the feat of the mariners of Pharaoh Necho, about 610 B. C.

The gimbal-joint and compass-box were invented by the Rev. William Barlowe in 1608.

The *dip* of the needle was discovered by Robert Norman of London, 1576; the diurnal variation, by Graham, a London watchmaker, in 1722.

An azimuth compass is one used at sea for finding the horizonal distance of the sun or a star from the magnetic meridian.

Lord Caithness has substituted for the gimbals a pendulum and a ball; the latter working in a socket in the center of the bottom of the compass-bowl.

Albini's self-registering compass is an instrument by which a continuous record is kept of the course steered by the vessel on board which the compass is placed. The compass-card carries on its under side, and near its periphery, a number of types or letters, which correspond with those denoting the points of the compass on the upper surface of the card. A continuous strip of paper, moved by clock-work, passes under the card at that side which is next the bow of the vessel, and between this paper strip and the card itself is an inked tape, which also travels slowly. At frequent regular intervals the compass-card is tilted, so as to bring the type which happen to be immediately above the paper strip at the time down upon the inked tape, bringing the latter in contact with the paper, and marking upon the latter the letters denoting the course which the vessel is steering at that moment.

When iron ships were first introduced, great difficulty was experienced in regard to the disturbance of the compass, owing to the vicinity of large bodies of iron. It was also shown by Grantham in 1842, and Scoresby in 1851, that the direction of the ship's head on the stocks, the effect of riveting in that position, the magnetic direction while fitting, each had an influence in determining the magnetic condition of the vessel.

Compasses are sometimes carried on the masts of iron vessels as a means of removing them from the disturbing influence of the iron of the hull. In this position they serve as standards of comparison for the binnacle compass.

The amount of deflection of the needle from its proper direction frequently varies on each point of the compass; while on one course it may indicate correctly, on another it may err from one to two points. The amount of this deviation is ascertained by anchoring the ship in a smooth and sheltered place with a very short scope of cable, and carrying out kedges so that she may be swung round and held in any required position.

The magnetic bearings of one or more conspicuous objects, at a sufficient distance to obviate any sensible parallax, are taken from the map or chart; the ship is swung, by the means before indicated, so that her head shall point successively to every point of the compass, and as the ship's head, during the operation of swinging, is brought in line with the object above mentioned, the compass bearing is noted, and at the same time angles are taken with the sextant to other distant objects on shore, whose position is known. A comparison of these angles with the bearings indicated by the compass shows at once the error of the latter.

Local deviation is not exclusively confined to iron ships; it is frequently quite perceptible in wooden men-of-war, occasioned by the attraction of the guns, and in vessels laden with iron the amount is often very great.

Professor Airey's method of adjusting compasses in iron ships is essentially as follows. Directly under the spot where the compass is to be placed two lines are drawn on the deck, one parallel with and the other perpendicular to the line of the keel. Two or three powerful magnets and one or two small boxes for holding chain are provided. The vessel's head is brought in the direction of one of the cardinal points, as ascertained by a compass on shore free from disturbing influences, and she is held in this position by hawsers. If the ship's compass indicates any deviation from the true bearing, one or more of the magnets is placed upon the deck at right angles to the magnetic meridian and moved backward or forward until the compass-needle indicates correctly. The ship's head is then turned 90°,

Digitized by Google

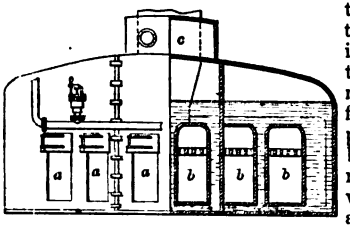
and the operation repeated until the compass-needle again points correctly. A similar process is employed to bring the needle into coincidence with the meridian at each of the other cardinal points indicated by the cross lines on the deck, and its correctness at each of the four rhumb points, N. E., N. W., S. W., S. E., is assured in like manner, using the boxes of chain before mentioned to correct the deviation of the needle. When these adjustments are made the compass should be sufficiently correct for all practical purposes. The deviations, if any, may be ascertained by swinging the ship.

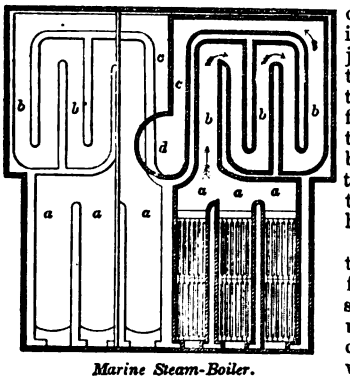
Gray's apparatus for adjusting compasses is based on the foregoing method of Professor Airey. The regulating magnets are caused to approach or recede from the compass by screws, so as to admit of very accurate adjustment.

Great care must be taken that the magnets are brought, by turning the ship at right angles, to the magnetic meridian before moving them, in order to regulate the compass.

Ma-rine' Steam-boil'er. Marine steam-boilers are composed of an external shell or casing, with rectangular sides, stayed together by tie-bars. Within it are contained the furnaces, the flues and ash-pit, the whole being surrounded by water except at the furnace front.

Fig. 3070.





Marine Steam-Boiler.

In some cases, the front is also water-jacketed, and the doors themselves are filled with water, circulation being maintained through the tubular hinges.

The flues for the passage of flame and smoke are deep rectangular channels, which, after making many turnings, unite in one common chimney or funnel.

The marine boiler shown in the illustration is composed of three parts, the sides of the middle boiler serving as a side to each of the outside boilers. At some distance above the water-line, large apertures are cut in the sides of the middle boiler, to form a steam communication between the three compartments, and a water communication is established below by a pipe from each boiler, opening into the blow-off main. The upper figure is an elevation, one half in section; *a a* are the fire-doors and *b b* the fire-chambers, *c* is the steam-dome.

Each boiler has two fireplaces, and the flues *a a* (lower figure) of the side boilers branch into the flues *b b* of the contiguous fireplaces of the middle boiler, immediately at the back of the bridge; and, after taking the circuitous course shown in the plan by the arrows, they unite at the back of the boiler and form one large flue *c*, from which the chimney *d* rises at about the middle of the length of the boiler. The flues are not divided horizontally, but extend the whole depth from *b* to *b*, as shown in the vertical section.

Towards the forepart of the middle boiler is a steam-chest, from whence proceeds the main steam-pipe, which conveys the steam to the cylinders. The feed-pipe and feed-valves are shown in the sectional view.

The separation between the boilers extends a considerable distance above the water-line, in order that their contents may not all be collected on one side of the vessel when she careens or rolls, uncovering some of the weathermost flues.

At the bottom of the boiler are pipes passing through the vessel's sides, and furnished with stop-cocks or valves, by which sediment or brine may be blown out of the boiler.

Mud-holes are used for cleaning out scale or sediment, and at other times are closed by doors.

In the *marine* steam-boiler the fire and flues are all contained within the boiler itself, and are surrounded by water in every direction as a precaution against fire. There are many varieties, known as *flue*-boilers, *tubular* boilers, *sheet-flue* boilers, etc.

Ma-rine' Steam-en'gine. A form, or one of the forms, of steam-engines adapted to use on shipboard.

The objects to be gained in the modification of the land engines to suit the change of circumstances are, —

Compactness, to save room on board and secure protection below decks.

A *low center of gravity*, to increase the stability of the vessel.

Napier's side-beam engine is the form which has been extensively adopted in paddle-wheel vessels, and is the one selected for illustration.

A modification of this is found in the *lever-engine*.

An endeavor to dispense with the beam has originated a variety of *direct-action engines* and *oscillating-cylinder engines*.

The figure represents in section a *side-beam engine* with a flue boiler as placed in a steam-vessel.

The sleepers supporting the engine are represented at *X*, and the base of the engine is secured to these by *holding-down bolts* passing through them. *S* is the steam-pipe leading from the steam-chest in the boiler to the slides *c*, by which it is admitted to the top and bottom of the cylinder. The condenser is represented at *B*, and the air-pump at *E*. The hot-well is seen at *F*, from which the feed is taken to the boiler. *L* is the piston-rod connected with the beam *H*, working on a center *K* near the base of the engine. The other end of the beam *H* drives a connecting-rod *M*, which extends upward to the crank on the paddle-shaft *O*. *a a* are the rods of the parallel motion. The framing by which the engine is supported is represented at *Q R*.

The beam exhibited in the figure is shown in dotted lines, as being on the farther side of the engine. A similar beam, similarly placed and moving on the same center, must be understood to be on the near side also, connected with the cross-head of the piston in like manner by a parallel motion, and with a cross-tail attached to the lower end of the connecting-rod and to the opposite beam. The eccentric which works the slides is placed upon the paddle-shaft *O*, and the connecting arm which drives the slides may be easily detached when the engine requires to be stopped. The section of the boiler, grate, and flues is represented at *W V*. The safety-

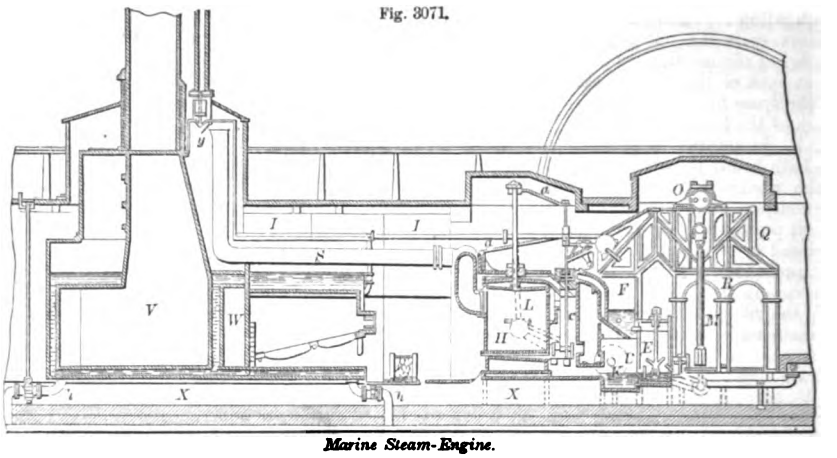
Fig. 3071.



Marine Steam-Engine.

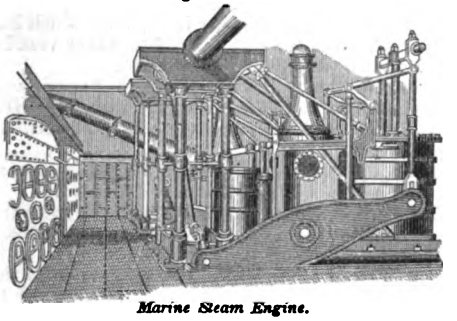
valve *y* is inclosed beneath a pipe carried up beside the chimney, and is inaccessible to the engineer. The cocks for blowing off the salt-water from the boiler are represented at *h*, and the feed-pipe at *I*.

Fig. 3072 is a view of a similar engine, looking down the alley between the boilers and the working parts.

The side-beam engine is very compact compared with the elevated working-beam engine, such as the *Cornish*, for instance, but the tendency of late years has been to direct action, dispensing with the beam.

The general adoption of the screw propeller has also much changed the general conditions required,

Fig. 3072.



Marine Steam Engine.

and oscillating engines of large diameter and comparatively short stroke are now the order of the day.

The following list includes most of the varieties of engines specially adapted to marine purposes. See under the respective heads: —

Annular-cylinder steam-engine.	Lever steam-engine.
Direct-action steam-engine.	Oscillating-cylinder steam-engine.
Double-cylinder steam-engine.	Propeller steam-engine.
"Gorgon" steam-engine.	Screw-propeller steam-engine.
Inclined-cylinder steam-engine.	Side-beam steam-engine.
Inverted-cylinder steam-engine.	Sliding-cover steam-engine.
Inverted double-cylinder steam-engine.	Steeple steam-engine.
	Trunk steam-engine.

Mar'i-no-ra'ma. A picture of a sea-view.

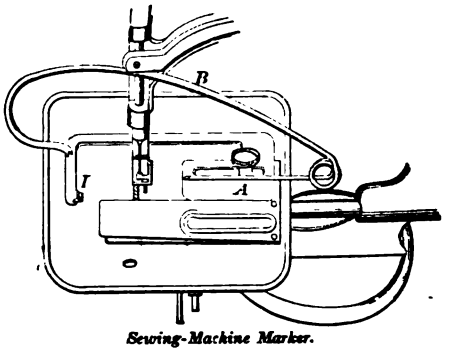
Mark. 1. Marks of manufacturers, sometimes termed trade-marks, or marks of merchandise. These marks are protected by all modern civilized nations, and, in fact, by the whole commercial world. The mark of the artisan is found upon the most ancient fabrics that have come to light. The Chinese, the Persians, the Egyptians, all had their distinctive manufacturers' signs, symbols which were intrinsic evidence of genuineness of origin of the articles of merchandise to which they were affixed. In the ruins of Herculaneum and Pompeii they are found. The Romans brought them to Britain, where the practice of using them has continued, probably without any intermission, from their time to our own. Antique pieces of pottery found in England furnish example. All nations protect the manufacturer in the exclusive use of his private emblem, and, by treaties, statutes, and judicial decisions, the most stringent penalties are inflicted upon one who pirates such a mark for his own fraudulent gain. The mark is, in fact, the commercial signature of the maker. All the early printers had their trade-marks, generally monogrammatic.

2. (*Nautical.*) One of the notifications of depth, on a sounding-line. See MARKS AND DEEPS.

Mark'er. An attachment to a sewing-machine for forming creases in or marks on fabric, so that it may be folded in line with such crease or mark for a tuck, and in a line parallel with, and at any desired distance from, another tuck.

Fig. 3073 shows a good form of the appliance. The plate *A* has an arm surrounding the feed-open-

Fig. 3073.



Sewing-Machine Marker.

ing and presser; on the end of the arm is the spur *I*. An arm *B*, notched at its forward end, is bent to form a spring, and is bent down by the needle-bar to form a crease in the cloth lying on the point *I*. For varieties of *tuck-creasers* and *markers*, see "Sewing-Machine Attachments," G. W. Gregory, Washington, D. C.

Digitized by Google

Mark'ing-gage. (*Carpentry.*) The marking-gage has a stem which carries a scribing point and a head or fence, which is adjustable on the stem and secured in adjustment by a set screw or wedge. As the scribe is drawn along on a board, the *fence* slides on the edge of the latter, and causes the mark to be parallel with the edge and at the regulated distance.

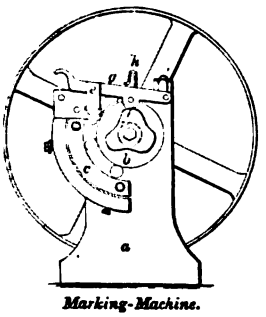
Fig. 3074.

Marking-Gage.

Mark'ing-ink. An indelible ink for marking clothes. See INK.

Mark'ing-ma-chine'. (*Coining.*) A machine used in the mint, to swage the edges of planchets for coin, raising the edge of the blank preparatory to *milling*. *a* is an iron frame in which is a horizontal shaft carrying a driving and a loose pulley and a fly-wheel; *b* is a flat, circular plate with a grooved edge; *c* is a plate with corresponding grooved edge, adjustable to the plate *b* by screws, and *e* a hopper in which the blanks are placed; *f* is a cam which, as it revolves, pushes back the feeder *g*, allowing the blanks to fall from the hopper. The spring *h* brings down the feeder *g*, which pushes a blank from the bottom of the hopper. The blanks slide down an inclined plane until their edges come between the plates *b* and *c*, and as the plate *b* revolves, the pressure of its edge carries them forward, and at the same time raises their edges all around, increasing the thickness by about one third.

Fig. 3075.



Marking-Machine.

Mark'ing-plow. (*Agriculture.*) One for running slight furrows in plowed land as a mark for planting corn, or, at greater distances, for sowing broadcast. Also used in crossing out land for planting an orchard.

Marks and Deeps. (*Nautical.*) The mode of indicating lengths on the hand lead-line. The *marks* have certain indications. The *deeps* are the estimated fathoms in the intervals of the *marks*.

Mark 2, leather.	Deep 12.
Mark 3, blue bunting.	Mark 13, blue bunting.
Deep 4.	Deep 14.
Mark 5, white bunting.	Mark 15, white bunting.
Deep 6.	Deep 16.
Mark 7, red bunting.	Mark 17, red bunting.
Deep 8.	Deep 18.
Deep 9.	Deep 19.
Mark 10, leather.	Mark 20, two knots.
Deep 11.	

Marle-stock. An English name for a kind of brick. A *cutter*.

Mar'line. (*Nautical.*) A small cord composed of two strands slightly twisted and used for lashing, sewing, and tricing. Used either white or tarred.

Marl'ing. (*Nautical.*) Wrapping a rope with spun-yarn or twine, having a knot at each turn to secure it if it become cut at one or more places. It differs from SERVING (which see).

Mar'lin-spike. (*Nautical.*) A pointed iron pin suspended by a lanyard, and used to make an opening between the strands of rope in splicing.

Mar'mo-ra'tion. (*Architecture.*) A casing of marble to a building.

Mar'mo-ra'tum; Mar'mo-re'tum. A cement made of pounded marble and lime for architectural purposes.

A cement of tin-foil and mercury, formerly used for filling decayed teeth.

White of egg and quicklime incorporated in a mortar.

Mar-o-quin'-leath'er. A leather, generally dyed red or yellow, and prepared at Astracan and vicinity. It is made from the skins of bucks and goats. See SAFFIAN.

Mar-quee'. A field tent or covering made of strong canvas to keep off the rain. Generally with a second canvas or *fly* a little above the tent proper.

Mar'quet-ry. Inlaid work. It includes *parquetry, reisner* work, *buhl, mosaic.*

The first of these is employed in the ornamentation of cabinet and furniture work. In buhl, the patterns are usually more elaborate, consisting of scrolls and similar curvilinear figures, and the works comparatively small, while marquetry proper is used for floorings, etc. The general manner of executing these varieties of work is, however, entirely similar, consisting in cutting the designs out of pieces of wood or plates of metal and inserting pieces of a different color.

The woods employed in marquetry may be of their natural color or stained to any desired tint. The pattern may include figures or devices of any kind. Even pictures or portraits may be produced by the contrast in color or arrangement of the grain of the woods. When the inlays are inserted, the work is reduced to a level surface with the toothing-plane, and then scraped with the joiner's scraper applied obliquely to the joints of the wood. This is sometimes so skillfully done that the work may be polished with its own shavings, but ordinarily the use of glass-paper is required to produce the requisite polish. Works in wood and metal or in pearl, ivory, or tortoise-shell and metals require the use of the file, followed by sand or emery-paper. (See BUHL; PARQUETRY.) This species of ornamentation was much in vogue during the past century, but is now comparatively rare.

The art of inlaying different pieces of wood to resemble mosaic is of great antiquity. It was practiced in Egypt at a remote period, and is shown in very successful condition about 1355 B. C. See the chairs, boxes, mummy-cases, and furniture of Rameses III. in the "Description of Egypt," by the French savans, about 1812. The book is in the Congressional Library.

The art was very popular in India in times of whose dates we can only guess. The Chinese, also, were early in the field, and excelled in this as they did and do in whatever requires patient toil and persistent, careful manipulation.

The Egyptian antiquities referred to embrace many different colored woods and metals. Among the Italian artists, black and white woods were first used, and were called *morescoes*. John, Abbot of Verona, introduced stained woods, and thereby added to the variety. He also introduced buildings and attempts at perspective representation.

Mar'ron. (*Pyrotechnics.*) A paper box strongly wrapped with twine and filled with powder; it is intended to imitate the report of cannon, and is fired by a piece of quickmatch projecting externally.

Mar-seilles'. (*Fabric.*) A heavy cotton goods, embossed in the loom.

Mar-sel'la. (*Fabric.*) A kind of twilled linen.

Mar-sil'ly-car'riage. A naval gun-carriage having no fore trucks, the front transom resting immediately on the ship's deck. It is used in the

Digitized by Google

United States Navy for mounting the 9-inch gun in broadside.

Mar'tel-de-fer. A hammer and pick forming a battle-axe, and used in the Middle Ages.

Mar'te-line'. A small stone-hammer (*u*, Fig. 3032) used by sculptors and marble-workers. It is pointed at one end and square or diamond-shaped at the other.

Mar'te-line'-chis'el. A sculptor's chisel, driven by a mallet or hammer, and used by artists or workers in marble. *q r s t*, Fig. 3032, show several forms.

Mar-tel'lo-tow'er. (*Fortification.*) A circular, isolated tower of masonry, named from Mortella Bay, Corsica, where a tower of this description was taken by an English naval force in 1794, after a prolonged resistance.

The capacity for defense excited so much surprise and admiration, that numerous towers were planted along the English, Irish, and Jersey coasts, in anticipation of the invasion of Napoleon I.

The tower is usually about 40 feet in hight, having two stories, and a shell-proof roof with a 4½-foot parapet. The walls are 5½ feet thick; the lower story is for stores, magazine, and retreat; the second is a casemate with embrasures; the roof is armed *en barbette* with a traversing gun, under a bomb-proof. The towers were erected on the coasts of Kent within range of each other.

The entrances are at a considerable hight above the ground, and the tower has a ditch and glacis.

Two of these towers are on the plains of Abraham, as outworks of the citadel of Quebec.

Mar'tin. A grinding-tool consisting of a brass plate with a flat stone facing. An opening through the plate and lining allows sand to pass through and insinuate itself between the *martin* and the stone which is being ground. A *runner*.

Mar'tin-et'; Mart'net. (*Nautical.*) A small line on the leach of a sail, to assist in handling it in furling.

Mar'tin-gale. 1. (*Nautical.*) *a.* A lower stay for the *jib-boom* or *flying jib-boom*.

The *martingale* of the former passes from the end of the jib-boom to the *dolphin-striker*, and is *set up* by *setting taut* the back-ropes of the latter.

The *flying jib-boom martingale* passes from the end of the spar, is rove through the end of the *dolphin-striker*, and is set up in the head of the ship.

b. A perpendicular spar under the bowsprit end, for guying down the headstays of a ship.

2. (*Harness.*) A strap from the nose-band to the girth, to keep a horse from throwing the head or rearing.

Or, a strap passing from the girth or belly-band and forking in front of the chest; at the ends of the bifurcations are two rings for the reins.

Mar'tin's Shells. (*Ordnance.*) Cast-iron spherical shells, lined with loam and cow-hair and filled with molten iron. Used as an incendiary shell.

Marv'er. (*Glass-making.*) From the French *marbre*, marble, a slab of that material being formerly used. A slab of marble or cast-iron, with a polished surface and supported by a stand. Upon it glass is rolled to give it a cylindrical shape. See GLASS-BLOWING. It sometimes has concavities for shaping glassware when blowing.

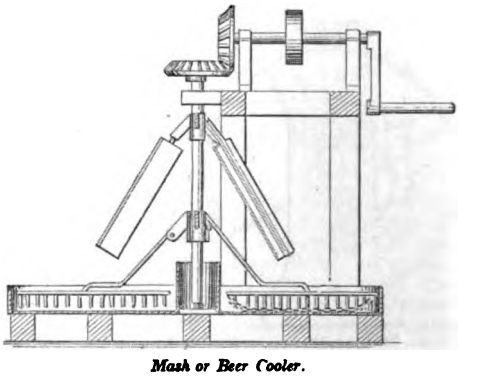
Mash. Crushed or ground grain, malt, or a mixture of the two, steeped in hot water so as to obtain an infusion consisting of the saccharine portions. The resulting solution is *wort*, and when decocted with hops and fermented it becomes beer; when simply fermented, it is *wash* for distillation.

The *mash* of the Scotch distillers is made of 40 bushels of ground barley, and 20 of crushed malt; this is infused in 750 gallons of water, at 150° Fah., for from 1 to 4 hours, and stirred. 500 gallons of water at 190° to 205° are admitted at intervals, to keep up the heat. After mashing, the infusion is allowed 2 hours to settle, and is then decanted.

The grains are repeatedly washed to extract soluble matter, the resulting liquid being boiled down or used as a steeping liquid in future boilings.

Mash-cool'er. A stirring-trough in which mash or wort are stirred to expedite the cooling. The rotary vertical shaft has its fans and stirrers; the former cause a circulation of air, and the latter stir the contents of the shallow circular tub.

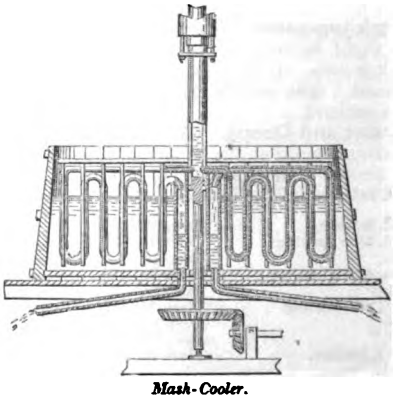
Fig. 3076.



Mash or Beer Cooler.

In Fig. 3077, coils of cold-water pipes are supplied from an axial pipe, and discharge into an annular chamber around the axis. The constant stream of water keeps the coils cool as they revolve in the mash.

Fig. 3077.



Mash-Cooler.

Mash'ing. Making an infusion of malt (called *wort*) by steeping and stirring in hot water. In the manufacture of vinegar, the cooled *wort* is fermented to form *malt-wash* or *gyle*, which is acetified by *fielding* or *stoving*.

Mash-tun. (*Brewing.*) The vat or cask in which malt is steeped, and from which the saccharine solution is drawn. A mash-tub.

Pliny tells us that the Egyptians made barley wine, because their country, being subject to periodical overflow, was not suitable for grapes. The Gauls also made beer, and, the same historian informs us,

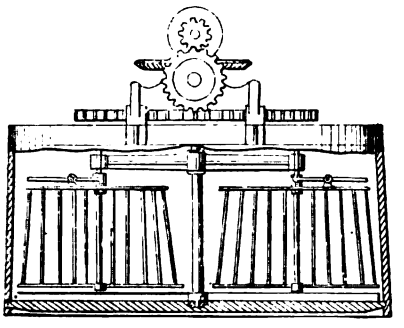
Digitized by Google

were the first to use yeast for raising dough for bread. The "froth of their barley wine," he calls it. This was probably twelve or fifteen centuries before the people added an infusion of hops to the wort.

Yeast is said to have been first used in England for bread-making in 1550.

Fig. 3078 shows a form of mash-tub which has

Fig. 3078.

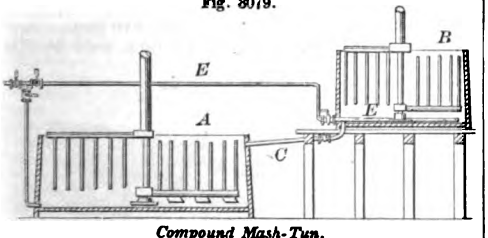


Mash-Tun with Stirrers.

rotating and revolving stirrers at the ends of an arm which is revolved by means of gear-wheels.

Fig. 3079 shows a compound tub for the use of

Fig. 3079.

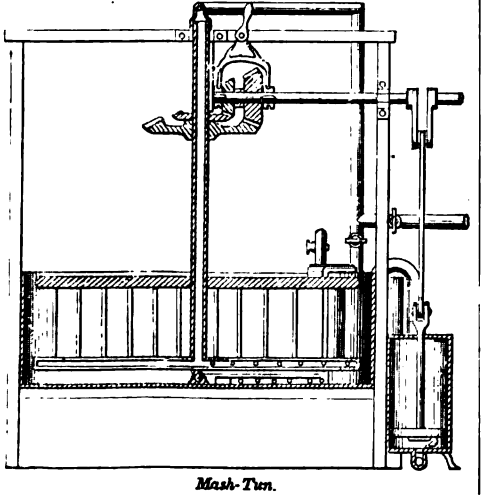


Compound Mash-Tun.

corn-meal with malt in making beer, or for mashing corn-meal to make wash for distilling.

The small tub *B* is placed higher than the large tub *A*, and is filled with water containing a quantity of corn-meal equal to the quantity of malt in the large tub *A*. Steam is admitted to *B* through perforations in the coiled pipe *E* at its bottom, until the corn-meal is entirely dissolved and the liquid is clear, like sirup. The liquid is then drawn off into *A* through pipe *C*, the fluid mass being kept all the time in motion by the stirrers.

Fig. 3080.



Mash-Tun.

In Fig. 3080 the vertical shaft of the rake is hollow, as are also the arms; through perforations in the latter a current of air and steam is poured for the purpose of boiling the wort, and subsequently a refrigerated stream of air for the purpose of cooling it. A stationary perforated pipe in the vat may be the medium of conveying the currents aforesaid.

Mask. 1. A face covering.

a. A wire cage to protect the face from a stray cut or thrust with a foil in fencing.

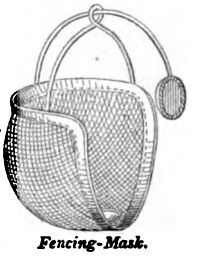
b. A face covering of a humorous or other character as a disguise.

c. A face protection to be worn in glass-works or foundries, to protect against radiant heat.

d. A face covering with a means of arresting particles of metal in dry grinding.

e. A form of inhaler which covers the face and affords a wholesome atmosphere to miners or firemen in positions of danger. See INHALER.

Fig. 3081.



Fencing-Mask.

2. (*Fortification.*) A cover of gabions or earth to protect workmen in constructing a battery; or a screen for a battery.

Masked Bat'ter-y. (*Fortification.*) A battery concealed from the view of the enemy by mantlets, bushes, or other screen.

Ma'son-ry. The art of so arranging stones or brick as to produce a regular construction.

The masonry of the ancient Egyptians was remarkable for the large size of the stones employed, sometimes as much as thirty feet in length. They were laid without mortar.

The Cyclopean or earlier masonry of the Greeks, some remains of which exist in the walls of Mycenæ and Tiryns, was formed of large and irregularly shaped masses of stone, the interstices being filled with smaller stones. Tyrrhenian or Etruscan masonry is also composed of similar stones, but so fitted together as not to admit of smaller stones between them. The more ancient remains of Greece and Italy afford examples of this kind of masonry. Peru also affords remarkable instances of cyclopean masonry.

To this succeeded the practice of making the beds horizontal or nearly so, but the vertical joints were irregular. All the preceding were laid without mortar. The Phœnician ashlar masonry is known by its bevel, and the specimens uncovered at Jerusalem are of surpassing interest.

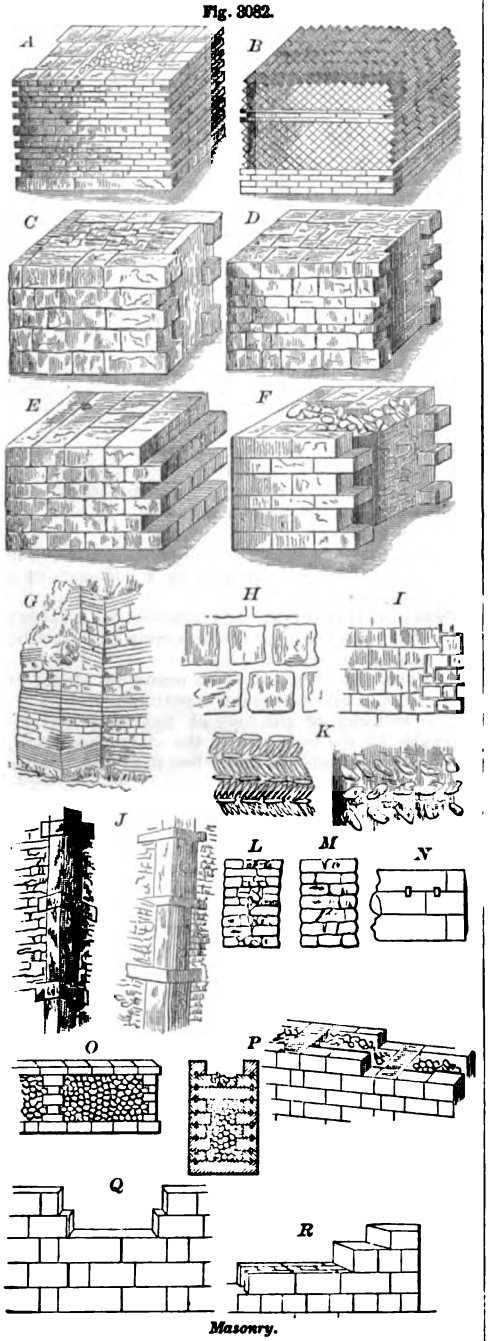
The Greeks and Romans used several methods for walling, as the *opus incertum*, *A*, Fig. 3082; *B*, *opus reticulatum*, formed of square stones laid diagonally; *C*, *isodomon*, in which the courses were of equal hight; *D*, *pseudisodomon*, in which they were unequal; *E*, Greek *emplectum*; *F*, Roman *emplectum*, of coursed work on the outside, the interior being of rubble. In these the stones were small and laid in mortar. Where large stones were used, no mortar was employed. The Roman emplectum found in England has sometimes courses of tiles built in, as shown at *G*. *H* represents wide-jointed masonry, and *I* a combination of wide and close joints.

In a few of the earlier English buildings, considered by some to be Saxon, the quoins, the door and win-

Digitized by Google

dow jambs, and occasionally some other parts, were formed of stones alternately laid flat and set up endwise; the latter were usually much longer than the others. This is termed *long and short work* (*J*).

Fig. 3082.



Masonry.

In the Norman period, *herring-bone work* (*K*) was frequently employed in rubble walls.

The stones used during the Middle Ages were seldom larger than could be lifted by two or three men.

The various kinds of masonry employed in modern practice may be divided into three principal classes:

Rubble work (*L*), in which the stones are not squared.

Coursed work (*M*), in which the stones are squared more or less and set in courses.

Ashlar (*N*), when each stone is squared and dressed to given dimensions.

O, rubble with cut-stone plinth, quoins, piers, and coping.

P, ashlar facing filled in with rubble.

Q. The stones of equal thickness laid alternately header and stretcher. The length of each stone is double its width.

R, a kind of masonry met with in Italy, composed of alternate courses of headers and stretchers.

The following are some of the technical terms employed to designate various species of mason-work.

Dressing is the working on the faces and beds.

Plane-ashlar; rubbed smooth.

Hammer-dressed; squared and picked by the hammer.

Broached; hewn by mallet and chisel.

Tooled or *drove*; the surface worked in parallel flutes.

Random-tooled; the tooling irregular.

Boasted or *chiseled*; wrought by a narrow chisel.

Nigged; dressed with a pick or pointed hammer.

Rough; axed on the face.

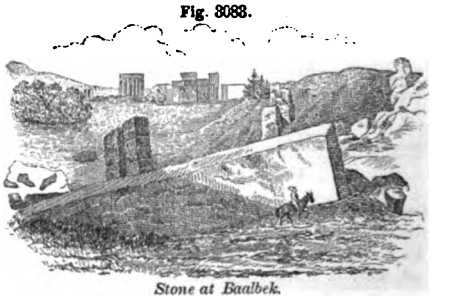
Rubble; a filling in with irregular stone.

Bowlder; made up of rounded unwrought stones.

Parpoint; squared stones laid in courses, with courses of *headers* at intervals of say five feet.

The largest stones ever placed in a wall by the hand of man are probably those in the foundations of the west and north sides of the temple of Baalbek. Thompson says: —

Fig. 3083.



Stone at Baalbek.

"The first tier above ground consists of stones of different lengths, but all above 12 feet thick and the same in width. Then come three stones, each more than 63 feet long. One of them lies in the quarry, where it can be viewed all round and measured easily. It is 14 × 16 and 69 feet long. It is 1½ miles distant from the temple." The stones are so well squared and jointed that it is difficult to find the crack, which indeed will not admit the blade of a knife. Dr. Thompson states he quite overlooked it at first, and supposed the stone to be 120 feet long.

The foundation is much older than the Greek temple which was built upon it and occupies a portion only of the area. The stones of the former building are believed to have been cut up to form the shafts, capitals, etc., of the Corinthian temple subsequently built. The original was probably the work of that great Asiatic nation of which the Phœnician people was an outlying branch, and possibly Arabia the home.

Ma'son's-lev'el. A plummet-level.

Mas'si-cot. (*Glass.*) The manufacturer's name for the protoxide of lead used in making flint-glass.

Mas-sool'a-boat. (*Nautical.*) A boat of the Coromandel coast, adapted to be beached on the surf-beaten shore. The planks are sewed together with coir, over wads of coir which press upon the seams. They are 30 to 35 feet long, 10 to 11 feet beam, 7 to 8 feet deep, and are rowed by 12 men,

Digitized by Google

oars double-banked, and a steersman with an oar at the stern.

Mast. (*Nautical.*) A long spar placed amidship, nearly perpendicularly upon the keelson, and serving to support the yards and gaffs to which the sails are bent.

Masts are known by a variety of terms which define their position or relation.

A mast consisting of one piece is a *pole-mast.*

Masts are also known as *single-tree* masts or *made* masts.

Masts for large vessels are composed of several pieces, about 1 foot square, with rounded segmental lengths on the outside, and the whole encircled at intervals by hoops. The middle tree is the spindle. The *fishes* are the side-trees.

With *two* masts: the larger is the *main*-mast, the smaller is the *fore*-mast or the *mizzen*-mast, according to its position relatively to the main-mast.

The *cap* is the block at the head of a mast, which forms a yoke for the attachment of the upper mast thereto.

The *hounds* are cheeks supporting the *trestle-trees.*

The *trestle-trees* are fore and aft timbers to support the *top.*

The *cross-trees* are timbers lying athwartship and scored down upon the *trestle-trees.*

The *top* is a flat platform to spread the shrouds of the upper mast, and for other purposes.

On the sides of the *top* are *futtock-plates*, having holes through which pass the *futtock-shrouds*, whose lower ends are secured to the chain-necklaces on the mast below the hounds.

The *fid* is a transverse key passing through the heel of the topmast and resting on the *trestle-trees.*

Iron masts are made hollow, the plates of the shell being single-riveted at the longitudinal joints and double-riveted at the circular joints. Internal stiffening ribs and braces prevent flexure, collapse, or torsion.

Tripod masts, invented by Captain Coles, English Navy, have three diverging legs, and obviate the use of standing rigging.

A *trysail*-mast is a small mast abaft the mizzen to carry a gaff.

A *spencer*-mast is a similar spar, abaft the *fore* or the *main* mast.

A *jigger* is a small mast, erected on the stern of a *yawl*, a vessel whose rig in other respects is that of a *cutter.*

Fig. 3084 shows the various spars and the most important ropes of a full-rigged ship.

66, cross-jack lifts.
67, mizzen-topsail lifts.
68, mizzen-topsail braces.
69, mizzen-topgallant lifts.
70, mizzen-topgallant braces.

This rule is thus stated by the authorities, but is not always adhered to in practice.

Brigs, by this rule, have *fore* and *main* masts.

The *ketch*, *brigantine*, and *schooner* have *main* and *mizzen* masts.

With three masts: they are called *fore*, *main*, *mizzen.*

With four masts: they are called *fore*, *main*, *main-mizzen*, *bonaventure-mizzen.*

The proportions of the different masts to each other are about as, —

Mizzen, 7; main, 10; fore, 9.

The portions of a mast consisting of several spars are termed, —

The *lower-mast*, *top-mast*, *top-gallant mast*, *royal-mast.*

The hight of a lower-mast has three subdivisions:

The *housing*; from the heel to the upper deck.

The *hounding*; from the deck to the *hounds.*

The *head*; from the hounds to the cap.

The *heel* of a mast is its lower end, and rests in the *step* on the *keelson.*

At the deck it is supported by *carlings* and *beams.*

Above the deck are cleats called *partners*, which form a rim around the deck-opening.

At the *hounds* the rigging is secured to the mast. The mast is stayed by *fore-stays*, *back-stays*, and *shrouds.*

The *head* is the portion to which the lower end of the topmast is secured.

83, bobstays.

Guppy's mast, English patent, 1826, consisted, instead of a single pole or spar, of a pair of spars stepped into the ends of the beams and uniting at the crosstrees, forming an isosceles triangle. Being hinged at the deck, they were designed to be lowered fore and aft, depending for their stability in use upon the stays.

Shuldham's revolving mast (English patent) is capable of rotation, so as to present the sails in the required direction by rotation on its axis, instead of veering the yards.

Here, as in regard to many other subjects, the Greeks credit Dædalus with the first invention. How many centuries previously the rivers of China, the Ganges, and the Nile had been dotted with sailing craft, it is impossible to say. A part of the corn which Joseph collected was probably brought in sailing-vessels to the depot, over 400 years before the date of the Athenian mechanic.

Icarus, says Pliny, was the person who invented sails, and Dædalus the mast and yards.

The ships of antiquity depended more upon rowers than sails, but were provided with masts and sails as accessories. Upon the Nile, the barges were propelled by sails generally, excepting that numerous class which partook of the character of rafts, were floated down the river, carrying produce, and were not returned up stream. One mast and one sail, the latter depending from a yard, is the general feature, though a plurality of masts was not uncommon, especially with large vessels, such as the galley built by Archimedes for Hiero of Syracuse. It had 3 decks, towers on the bulwarks, stables, libraries, baths, fish-ponds, a crew of 600 men, and a main-mast that came from England. This was about 240 B. C. (See SHIP.) Syracuse was captured by Marcellus 212, and Archimedes slain. The mast is presumed to have been brought by the Phœnician or Carthaginian navigators from England, as those maritime nations were yet in existence. Poor Tyre had been desolated by Alexander 100 years before, but the people dispersed around the Mediterranean were yet active, and Carthage had not fallen before her imperial rival, remorseless Rome.

In the time of Isaiah the masts were strengthened with shrouds from the deck or bulwarks. A few years later we read that the Tyrians obtained cedar masts from Lebanon, as no doubt they had been doing for 1,000 years before Ezekiel wrote. The planking of the vessels was "fir-trees of Senir" (Hermon), calked by men of Gebal; the oars of oak from Bashan; the rowers' benches of ivory from the "Isles of Chittim" (some western land on the African coast). The sails were fine linen of Egypt, the awnings of purple and blue fabric "from the Isles of Elishah." Josephus identifies the descendants of Elishah, the eldest son of Javan, with the Æolians. So Greece furnished the Tyrian dye. Lydia of Thyatira, a seller of purple, was converted A. D. 53, under the preaching of Paul of Tarsus. This was in or near the ancient Æolia, so that the local profession was yet preserved.

Mast-car'ling. (*Shipbuilding.*) Large timbers at the side of the mast-rooms that are left deep enough to receive the cross-chocks.

Mas'ter-key. A key which commands many locks of a certain set, the keys of which are not interchangeable among themselves. While neither one of a series of keys may suffice to open any lock besides the one for which it was constructed, a master-key is one which may operate any one of the set. In the annexed series, the key No. 4 is master of the locks for which the keys Nos. 1, 2, and 3 are specially constructed.

Fig. 3085.

(*No. 4*) *Master-Key.*

Mas'ter-tap. A *tap-screw.*

Mas'ter-wheel. The main wheel in a machine which acts as a driver of many parts. Such is the large cog-wheel in a horse-power which imparts motion to a circular system of pinions. See HORSE-POWER.

Mast-hole. (*Shipbuilding.*) A hole in the deck to receive a *mast.* It is of larger diameter than the mast by double the thickness of the wedges which hold the mast in position.

The framing of the mast-hole consists of *fore-and-aft partners, cross-partners,* and *corner-chocks.*

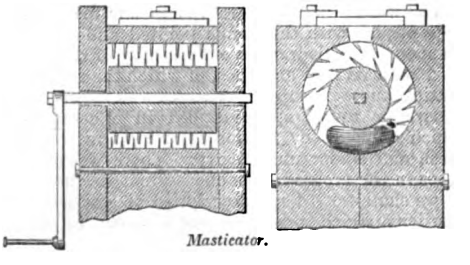
Mast-hoop. A circular band to which the luff of a fore-and-aft sail is bent, and which slips on a spar in raising and lowering. In the example, the hoop is composed partly of wood and partly of metal, the metallic portion being provided with friction rollers.

Fig. 3086

Mast-Hoop.

Mas'ti-ca-tor. 1. A small machine to cut up meat for aged persons or those who have lost their teeth or the power of chewing. It is screwed to the table; the food is fed in at the top, and a crank to which a number of sharp knives are attached is turned in opposition to a number of stationary ones. This minces the food, and deposits it on the plate of the person. Food cut up in this manner retains all the nourishing qualities. The interior

Fig. 3087.



Masticator.

of this machine is lined with porcelain, and is easily kept clean. See MEAT-CHOPPER; MEAT-CUTTER; SAUSAGE-MACHINE.

2. The machine which kneads the raw caoutchouc to render it homogeneous.

Mast'ing-shears. A hoisting device consisting of two spars and one or more guys, used to elevate masts on end to put them in position aboard vessels, or remove them from vessels. See SHEARS.

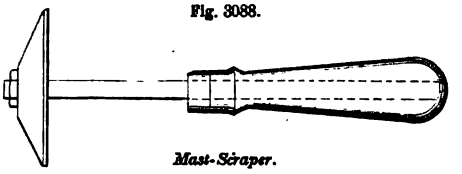
Mast-prop. A spar forming a lateral support for a mast when a ship is careened.

Mast-scrap'er. A tool for scraping masts; it is usually a triangular plate with an edge whose bevel is away from the handle. Its edge is sometimes partly concave, to more nearly fit the contour of the mast.

Mast-step. A socket at the foot of a mast.

Digitized by Google

Fig. 3088.



Mast-Scraper.

Mast-tack'le. (*Nautical.*) *a.* Purchases used in putting up or sending down masts.

b. Purchases attached to the mast for lifting or lowering boats, getting in freight or stock, bulky stores, machinery, blubber, etc.

Mast-trunk. (*Nautical.*) A box, in small vessels, in which stands the mast.

Mat. 1. (*Nautical.*) A wad of woven or thrummed junk. Used to secure standing rigging from the friction of yards and ropes.

2. (*Domestic.*) *a.* A rug of straw, rushes, husks, coir, junk, hemp; a tufted fabric of these materials or of wool; a skin with the hair or wool on; a set of slats, etc. Mats are for cleaning shoes at a door; keeping the feet from a cold floor, as in cars or halls, and elsewhere; covering up plants against frost, etc.

b. A small piece of oil-cloth, fabric, or worsted work, to place beneath a hot dish or wet pitcher, to preserve the polish of a table.

3. (*Photography.*) An ornamental plate or passe-partout laid over a daguerreotype, etc., and forming an oval or other symmetrical border to the picture, as well as keeping the plate from abrasion by the glass.

4. (*Metallurgy.*) An alloy of metals in a crude form, in the process of reducing. *Matt, matte.*

Match. 1. A splint or strip of combustible material, usually wood, one end of which is dipped in a composition that ignites by friction.

The earliest and most primitive way of obtaining fire by artificial means seems to have been that still in use among the South-Sea-Islanders and other savage tribes, by rubbing two sticks of dry wood together. To this succeeded the flint, steel, and tinder-box, and to them various forms of friction-matches and chemical devices.

The word "matches" recalls to our memory the slips of pine with their ends pointed and dipped in brimstone. This was the old associate of the tinder-box, with its flint and steel, of which the rising generation knows nothing. A *match* now means a little square or round splint dipped in a composition which explodes by friction, and renders the flint, steel, and tinder unnecessary. There were several steps in the progress from one system to the other, as we shall see. For a description of a series of inventions which preceded *matches*, see LIGHTING-DEVICES.

About 1820, the first attempt may be said to have originated to dispossess the old flint and steel dynasty, though as long ago as 1677 the German chemist Kra'ft had indicated the uses of phosphorus for procuring light or fire. Boyle, at this period, describes it as "a factitious, self-shining substance," procurable in small quantities at great expenditure of time and labor. In 1680, Godfrey Hanckwitz, at his laboratory in Southampton Street, London, manufactured and sold large quantities of phosphorus for the purpose of striking light.

About 1825, the hydrogen-lamp was invented by Dobëreiner, a German, and was long in favor. It consisted of a piece of spongy platinum, which was rendered incandescent by the passage of hydrogen. See HYDROGEN-LAMP.

About the same time we hear of a composition of phosphorus and sulphur placed in a vial, and used by dipping a match and then rubbing the composition on the cork to excite ignition.

Then followed the match dipped successively in sulphur and then in a mixture of sugar and chlorate of potash. These were lighted by dipping in sulphuric acid.

The "Promethean" matches were made of a roll of paper treated with sugar and chlorate of potash and a small cell containing sulphuric acid. This cell was broken with a pair of pliers, and the acid ignited the composition by contact therewith.

Next (about 1834) we find the "Lucifers," which were coated with a mixture of sulphide of antimony and chlorate of potash made into a paste with gum-water, and ignited by drawing between the surfaces a folded piece of sand-paper.

The "Congreve" next appeared, in which phosphorus was substituted for sulphide of antimony.

In March, 1842, Reuben Partridge patented a machine for making splints.

1845, Schrötter of Vienna discovered amorphous or allotropic phosphorus, which rendered the manufacture less unhealthy, and the matches less dangerous.

The process of manufacture is, according to Tomlinson, as follows:—

Thick pine planks are cut into blocks by a circular saw, and these are divided into splints by a series of lancets in a reciprocating frame, which score the face of the block to a certain depth. A scythe-shaped knife, cutting the whole width of the block, then swings round and severs the row of splints. This produces square matches.

Circular matches are made by pressing the block against a plate having circular perforations, the interspaces between which are beveled so as to form cutting edges.

As the splints fall from the cutting-machine they pass down a shoot into an apartment below, where they are tied up in bundles of half a gross, after which they are dried in a hot room.

Each end of the bundle is next dipped in a pot of melted sulphur, and another string is tied around it, so that when divided by the circular saw two complete bundles are formed. They are now dipped in the phosphorus composition, the ingredients of which vary somewhat among different manufacturers, but consist essentially of nearly equal proportions of phosphorus, glue or gum, and fine sand (whiting is preferable), with coloring matter added, the whole mixed with water. Heat is applied in incorporating the materials, and the vessel containing them is maintained at a temperature of 98° in a water-bath. The composition is spread on a steam-heated slab. The matches are prepared for dipping by inserting them singly in a perforated frame containing fifty matches, from which each end of the splint projects. A boy then takes each frame and presses the ends of the matches upon the composition on the slab. They are next dried and boxed, which latter operation is performed, at the rate of 3,000 boxes per day, by little girls. Since the above was written more expeditious methods have been adopted.

The modes of operation in the United States differ somewhat in different establishments. The whole work is, however, done by machinery.

By one mode the splints are cut by a small machine containing 12 circular cutters, and carried by an endless chain 200 feet long, the sides of which are grooved to hold them to the sulphur-bath, imperfect splints being dislodged on the passage by the upward blow of a small hammer.

A wheel, revolving in the bath of molten sulphur, gives their ends a coating as they pass, after which they are carried 40 or 50 feet farther, where a similar

Digitized by Google

wheel touches their ends with phosphorus. They are carried by the chain about an equal distance onward, where the chain passes over a wheel, descending perpendicularly to the trays for receiving the matches, which, as they arrive, are pushed from the chain by a slider, and received in the trays.

Eight of these machines make 800 gross, 14,400 each, of matches daily. 600,000 feet of pine lumber, 250,000 feet of bass-wood for packing-cases, 300 barrels of brimstone, and 9,000 pounds of phosphorus are annually consumed.

Making the splints is in general a separate branch of the manufacture, as they can be made cheaper by machinery on a larger scale. See MATCH-SPLINT MACHINE.

A factory in New York State uses annually 720,000 feet of pine for matches, and 400,000 feet of bass-wood (linn) for cases; of sulphur 400 barrels, and phosphorus 9,000 pounds. The daily consumption of paper is 500 pounds, and of pasteboard for large boxes 8,000 pounds weekly. The daily consumption of paste is produced from 66 pounds of flour, and the one cent stamps used daily foot up the amount of $1,440.

Some matches are made without sulphur, thus avoiding the offensive smell of that mineral. A German composition for this purpose consists of phosphorus, 4 parts; water, 10; fine glue, 6; red ocher or red lead, 5; smalt, 2. The ingredients, in the order named, are incorporated with the liquefied glue to form a paste.

The ends of the splints are, in some cases, dipped in paraffine, to secure more ready ignition.

It has been proposed to employ sodium instead of phosphorus in the manufacture of matches. It ignites as easily, and is free from offensive odors.

A scientific journal strongly deprecates the idea, and cautions the public against the use, as sodium is so readily oxidized as to burn when wetted.

2. (*Ordnance and Mining.*) A *slow*-match consists of loosely twisted hempen cord dipped in a solution of saltpeter and lime-water. It burns at the rate of one yard in three hours.

A *quick-match* is cotton coated with a composition of mealed powder, gum, and water. When not confined it burns at the rate of one yard in thirteen seconds.

Another *quick-match* is made of cotton-wick boiled in saltpeter and water. Alcohol is added to the warm solution; mealed powder is added, and the wick left to steep for 24 hours. The match is then dried.

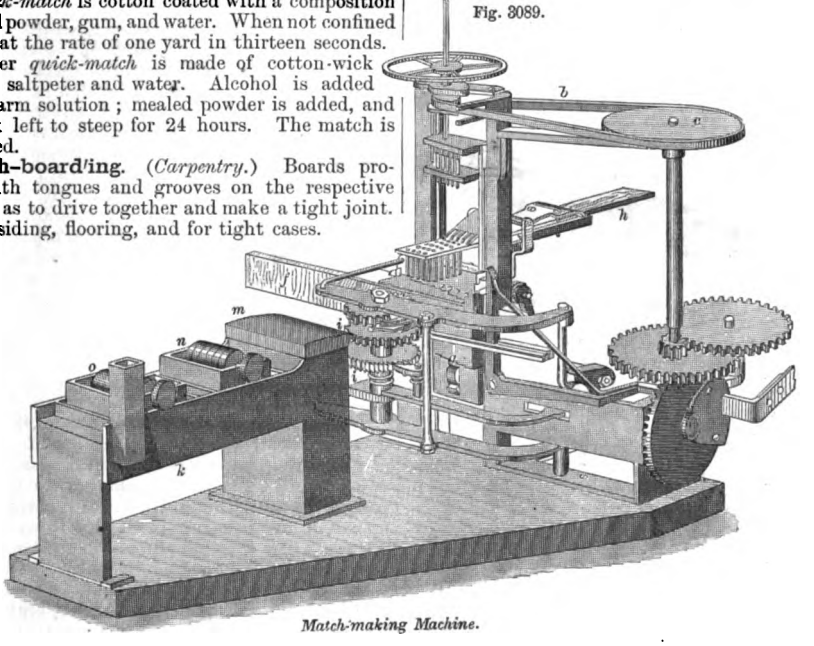
Match-board'ing. (*Carpentry.*) Boards provided with tongues and grooves on the respective edges, so as to drive together and make a tight joint. Used in siding, flooring, and for tight cases.

Match-box Ma-chine'. In Poirier's machine the boxes are made of pasteboard, which is cut into pieces each of suitable size to make the body or the top of a box. These pieces are rectangular in form, but are rounded at the angles. They are introduced one by one into the machine, and are instantly forced by a plunger into a box-shaped matrix or socket, where they receive at one movement the form desired. In this operation the corners, in which the material is in excess, are folded over on the sides, and an energetic pressure is exerted on the folds by means of four cams; in consequence of which these folds become compacted into one mass with the sides of the box. The capacity is 3,000 per hour.

Match-cloth. (*Fabric.*) A coarse woolen cloth.

Match-dip'ping Ma-chine'. Schmidt's match-dipping machine at the Paris Exposition was arranged for dipping 6,000 matches in four minutes. The splints, properly cut and prepared, are received upon a horizontal plate or table grooved to the size of the matches, and are made to fall into the grooves by the action of a broad brush which is suspended above the table, and which the operator moves by means of a pedal. In front of the table on which the matches thus arranged lie, is a frame placed vertically, which is designed to receive a number of layers of matches, one above another. This frame presents immediately before the row of matches a narrow receiving-plate or bed. By the action of a second pedal the workman causes a row of needles to advance, which push forward the matches on to this plate, and are retracted by a spring. The matches are pushed beyond the edge of the receiving-plate just so far as may suffice for dipping, and their ends are kept separate by thin partitions, which are a fixed part of the machine. The frame, which has a movement up and down in guides, is then depressed sufficiently to permit another receiving-plate to be laid on the last row of matches, at a proper level to receive an additional row; and this process goes on until sixty rows, each containing one hundred matches, have been piled up in the frame. The frame is then locked up by bringing down a traverse

Fig. 3089.



Match-making Machine.

Digitized by Google

bar at the top, so as to compress the whole mass and secure it in place. The matches are thus confined as in a printer's chase. They are then evened at their end like type, and are ready for dipping. — *Dr. Barnard's Report Paris Exposition.*

Match-gear'ing. (*Gearing.*) Two cog-wheels of equal diameter geared together.

Match-hook. A double hook or pair of hooks in which one portion forms a *mousing* for the other.

Match'ing-ma-chine'. A wood-planing machine which tongues and grooves the respective edges of a board. See MOLDING-MACHINE.

Match'ing-plane. See MATCH-PLANE.

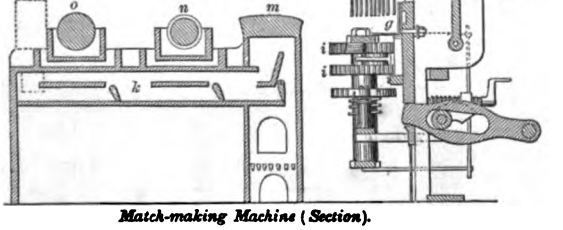
Match-lock. The form of gun-lock which preceded the wheel-lock and the flint-lock. It had a match, whence its name, which was presented to the priming. Still used in some parts of Asia. See REVOLVER.

Match-mak'ing Ma-chine'. Young's match-machine cuts the splints from a block or bolt of wood, sticks them singly in a strip of thin board, and passes them, points downward, over a trough or vat containing the chemicals, which are applied and the matches completed before the strip leaves the machine.

Fig. 3089 shows Young's machine. A gate carries a set of boring bits above and as many cutters *g* below. The bits are geared to run together at uniform speed, and are driven by belt *b* from pulley *c*. These bits are to bore holes in the strip *h*, into which all the matches are stuck as soon as cut from bolt *f*. *i i* are feed-wheels to bring the bolt of match timber to the cutters. *k* is a steam-chamber to heat chemicals and char the end of the splints as they pass over the block *m*, and *n o* are cylinders which apply chemicals to the splints as they pass.

The gate which carries cutters and bits being drawn up, the block is fed under the knives, which, in their descent, cut square splints from the block. The strip of board is then fed

Fig. 3090.



Match-making Machine (Section).

under the bits and over these newly cut splints. The bits bore a hole for each splint, then retreat, and by the farther descent of the gate the ends of the splints are forced into their respective holes in the slip *h*. The farther progress of the slip applies the chemicals, the slip advancing one row of matches to each descent of gate.

After the matches have been completed by the machine and dried a suitable time, they can be removed from the strips of wood and packed in boxes, or they may be sold adhering to their backing, in which condition they are known as *block matches.*

Fig. 3090 is a transverse section of the same machine.

Match-planes. A pair of planes making a tongue and groove respectively, the former to fit the latter. Used in making tight joints on meeting edges of boards.

Adjustable match-planes have moving fences to determine the distance of the tongue or the groove from the working edges of the respective boards. For varying widths of grooves and tongues different *irons* are used.

Fig. 3091.

Match-Joint.

Match-plate. (*Founding.*) A plate upon the opposite sides of which the halves of a pattern are placed correspondingly, to facilitate the operation of molding. The plate is placed between the parts of a flask, rammed up from both sides, and removed, allowing the parts to come together.

Match-safe. A box to contain matches for use. Usually hung up near a gas-bracket or elsewhere within ready reach.

Match-splint Ma-chine'. Matches of cylindrical form have been made by compressing the quadrangular slips or drawing the wood through holes in a draw-plate. The Austrian circular matches are cut from planks of clean grained wood, by means of hand-planes carrying a series of steel tubes, which produce long, thin splints of wood of circular section. These are afterward cut into lengths.

In Rimailho's machine the block of wood is the length of the match. The machine has a slide carrying a series of tubes made out of a solid piece of steel and kept sharp at their edges; a frame keeps the wood in contact with the tool. The slide is moved rapidly backward and forward by an eccentric, and cuts a row of matches at each stroke, each fresh row throwing out those previously made.

De Bowen's machine consists of a wheel 20 feet in diameter, and 6 feet across the face, supported on a frame of heavy timbers, and resting on a stone foundation 25 × 12 feet in length and width, and 5½ feet deep, laid in cement. This ponderous foundation is required in order to maintain the necessary accuracy and steadiness in the wheel, which makes 21 revolutions per minute. The blocks are clamped to the face of the wheel. A rest, similar to that of an iron lathe, and moved to the right or left in like manner, is placed in front of the breast of the wheel, and carries 16 annular steel cutters. The number of these may be doubled if necessary.

They are adjusted so as to face the blocks, and as the wheel revolves each cuts a splint out of the wood, which drops below. The cutters are advanced forward the exact thickness of a splint at each revolution of the large wheel, until they have cut through the thickness of the blocks, 6, 8, or 10 inches, when they are brought back to their original position by turning a wheel. The cutters are adjusted to cut the splints out of the projections left between the corrugations made by them in the blocks at the preceding revolution of the wheel. It is said that each machine, with 16 cutters, will cut 86,400 sticks per minute, 5,184,000 per hour, or 51,480,000 in a working day of 10 hours.

The sticks fall from the cutters in a shower into a trough below, through which passes a belt that carries them to a series of shakers having latticed bottoms, through which imperfect sticks and pieces of shavings drop. They are then deposited in cases with latticed bottoms and conveyed to the drying-rooms, where the boxes are placed in tiers, three or four deep, upon steam-pipes heated to a temperature of 120°, where they are allowed to remain a day and a night, effectually drying the wood. After drying they are arranged in parallel rows by another series of shakers and packed in boxes. They are then ready for shipment to the manufacturers, who perform the

Digitized by Google

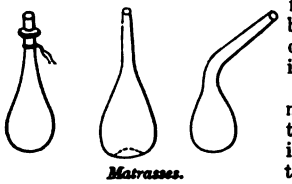
dipping process, that being a separate branch of the manufacture.

Match-tub. A tub about eighteen inches high, in which a slow-match is hung, fire downward.

Match-wheel. A cog-wheel adapted to mesh into or work with another.

Mat'rass. (*Pharmacy.*) A glass vessel with a long neck, a rounded body, and sometimes furnished with a tube. It is used for distilling and digesting.

Fig. 3092.



Matrasses.

Ma'trix. 1. A mold which gives form to an object driven into it or hardening therein, as, —

a. The intaglio or indented device for a coin, either engraved or produced from a *hub* on which the design has been produced in relief. The *matrix* is the mold into which a soft steel *plug* is driven, and which is to be used in making the *die* from which the coin is struck.

The series is as follows: —

1. The engraved *hub* (cameo).
2. The *matrix* (intaglio).
3. The *punch* (cameo).
4. The *die* (intaglio).
5. The *coin* (cameo). See DIE.

b. A bottom die or *bed.*

c. The *mold* in a type-making machine which gives the form to the letter on the end of the type. The letter is originally engraved on the end of a piece of steel, which is subsequently hardened, and is called a *punch.* The *punch* is used to impress the *matrix.*

Fig. 3093.

Matrix.

d. The plaster mold (in intaglio) obtained from a form of type, and used to obtain an impression (cameo) in type-metal, known as a STEREOTYPE (which see).

e. A matrix in paper is obtained by dabbing down upon the surface of the type successive sheets of unsized, thin paper, with occasional layers of paste. The dabbing is done by a brush, and thus the paper is forced into every crevice of the type. The matrix is then dried and used similarly to a plaster mold. If intended for a *turtle,* it is bent into cylindrical form before casting the metal upon it. The process is much used in newspaper work.

f. A mold for casting. A shape in which anything is formed.

2. The *gangue* or stony substance in which metalliferous ores are formed, associated, or imbedded.

Matt. 1. (*Metallurgy.*) A mass of imperfectly reduced metal having impurities, mineral and metallic, as in the case of copper. See COPPER-FURNACE.

2. (*Gilding.*) The *dead* or unburnished surface of gold, when the gold-leaf is merely pressed upon the size and is not rubbed with the burnisher. The dead appearance of portions acts as a foil to the lustrous surface over which the burnisher has passed. See GILDING.

Mat'ted-glass. (*Glass.*) A mode of ornamenting glass for windows, in which the surface is covered with a very fusible powder, either opaque, white, or tinted. This being removed in portions, the glass is fired and the composition fixed, giving a bright pattern on a dull ground.

Substantially the same effect is produced by painting the pattern on the glass with an asphaltum varnish, and then etching the surface with hydrofluoric acid.

By a similar process the glass bottles of the chemist have their labels ineffaceably inscribed.

Mat'ter. (*Printing.*) Type composed. It is *live, standing,* or *dead,* according as it is ready for use, awaiting re-use, or ready for distribution.

Mat'ting. 1. Matting is made of hemp, coir (the fiber covering the cocoa-nut), jute; also of rushes, hair, grass, palm-leaves, etc. The India matting is made of a peculiar Oriental grass. Russia matting of *bast* or linden bark. Also of strips of black-walnut or other ornamental wood, with wires passing through them at right angles. The wooden strips are separated by elastic washers made from india-rubber tubing. The matting can be rolled up into a compact form for transportation, and is found to have superior advantages for hallways of tenement-houses, street-cars, reception-rooms of hotels, railway depots, etc.

2. The passepartout over a picture. A *mat.*

3. (*Gilding.*) Covering plates with varnish in gilding on water size.

4. A regular rough lusterless surface.

Mat'ting-loom. (*Weaving.*) One in which slats are introduced into the shed to form the woof.

Mat'ting-tool. (*Metal-working.*) A kind of chasing tool, employed in producing a regular rough surface on an object; usually in the lathe.

Mat'tock. An implement with an iron head, having blades at each end presented in different planes, and an eye in the middle into which the handle is inserted perpendicularly to the head. The cutting edges are presented like those of an axe and an adze respectively.

The mattock, pick, grubbing-hoe, or a tool substantially similar and used for digging and grubbing, has been in use in Egypt and Palestine for nearly 4,000 years, as we know, and probably much longer.

The Egyptian hoe of the time of the Pharaohs was a large wooden implement, and answered for mattock, spade, and hoe. It had a single head, like the *surculus simplex* of Palladius, in contradistinction to the *bicornis,* or two-bladed tool, which resembled our pick. See HOE.

"They had a file for the mattocks." — 1 Samuel, xiii. 21 (1093 B. C.). By reference to Isaiah vii. 25, it appears that the mattock was relied upon for grubbing out briers and thorns as at present, and the pronged hoes of the Greeks had a similar duty in addition to their ordinary use in preparing the ground for seed.

Mat'tress. A padded bed, or one stuffed and quilted or tied, so as to keep the stuffing to a general thickness. The filling is hair, moss, sponge, cotton, husk, straw, *excelsior* (shredded wood), etc.

An elastic bed-bottom of coiled or woven wire.

Maul. A large wooden hammer, adapted for driving wedges, and sometimes called a *beetle.* (See MALLET.) A knot-maul (*x*, Fig. 3032) is made of a tough piece of timber, generally a knot chopped out of the side of a log. It is usually the frustum of a cone, the handle being inserted into an auger-hole bored through the axis and fastened by a wedge at the end.

The ring-maul (*y*, Fig. 3032) is a piece of a tough stick, gum, dogwood, hickory, or oak, with a hole passing transversely through it for the handle, and rings upon the ends to prevent splitting.

The iron-maul (*z*, Fig. 3032) has recessed faces to receive disks of wood, which are the working faces of the maul, as it is not fit that the iron should touch the object to be driven. A good maul is a valuable tool; and this iron-head, if carefully used,

Digitized by Google

will last a long time, the wooden faces being burned out when worn, and then renewed.

The light *maul* of the United States artillery service has a head of elm or hickory, 6 inches in diameter and 8 inches long; handle of ash, 1½ inches diameter, 24 inches long; an iron hoop on each end of the head 1 inch wide, ¼ inch thick. It is used for driving pickets. Weight, 10 pounds.

Maul-stick. (*Painting.*) A wooden rod on which an artist rests the right hand to steady it.

Maun'dril. (*Mining.*) A prying pick with two prongs.

Max'i-mum Ba-rom'e-ter. A barometer having an indicator so arranged as to follow the movement of the mercury up to the highest point which it may reach, and there remain stationary when the mercury recedes, thus showing the maximum hight of the column and consequent maximum of pressure during storms, etc.

Negretti and Zambras's contrivance for this purpose consists in jointing to the longer leg of a siphon barometer, at 8 inches from its top, a bent glass tube, which is carried up for 6 inches parallel to the main tube, joining it again at 2 inches from the top. The mercury flows freely in and out of this tube, maintaining the same level as that in the larger tube. It contains a small piece of steel, maintained in position by fine glass springs; as the mercury rises, the steel is pushed up, but remains stationary when the mercury descends. A similar contrivance in the shorter leg shows the minimum reading of the barometer.

Max'i-mum Ther-mom'e-ter. A thermometer arranged to register the highest point reached between observations, as Rutherford's. See THERMOMETER.

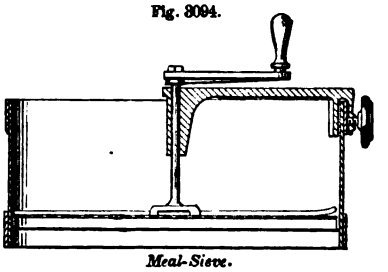
Meak. A hook with a long handle.

Mealed Pow'der. Gunpowder pulverized by treating with alcohol.

Meal'er. A wooden rubber for mealing powder.

Meal-sieve. (*Domestic.*) One for sifting cornmeal and flour, to remove portions of hulls from the former, lumps and weavil from the latter. The frame

Fig. 3094.



Meal-Sieve.

which rotates above the foraminous surface of the sieve is journaled in a frame attached by a clamp and set screw to the edge of the sieve.

Meas'ure. 1. A quantity assumed as a unit. See UNIT.

The measures of antiquity — and the modern have much the same origin — are derived from the parts of the human body.

The *finger-breadth* (*digitus*).

The *thumb-breadth* (*pollex*).

The *palm*, or hand-breadth (*palmus*).

The *span*, or distance comprised between the tips of the thumb and little finger when extended.

The length of the *foot* (*pes*).

The distance from the elbow to the tip of the middle finger (*cubit*).

A *step* = 30 inches (*gradus*).

A double-step or *pace* = 5 feet (*passus*).

The reach of the extended arms = 6 feet (*orgyia*).

The inch was not a unit of measure, but is the twelfth of a foot. The Greek measures were decimal, the Roman duodecimal.

The itinerary measure of distance was the *stadium*, the length of the foot-race course. The Olympic stadium was 600 feet.

The Roman measure of area was the *jugerum* = ⅘ of an acre English. Its name and quantity signify that it was a day's [illegible] for a *yoke* of oxen in plowing.

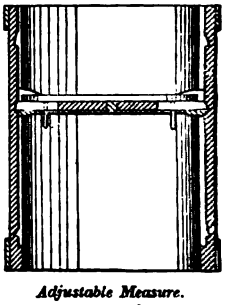
The *mille passuum*, or 1,000 paces, was the common name of the Roman mile.

A common Roman measure for land was the 10-foot pole, *pertica* or *decempeda*.

The unit of measure differs among different nations. See UNIT; METRIC SYSTEM.

Measures of merchandise and artificers' work are according to custom and trade: the yard and its fractions for woven goods; the fathom for rope; the bushel, peck, and gallon for grain and roots; the gallon and its subdivisions for liquids.

Fig. 3095.

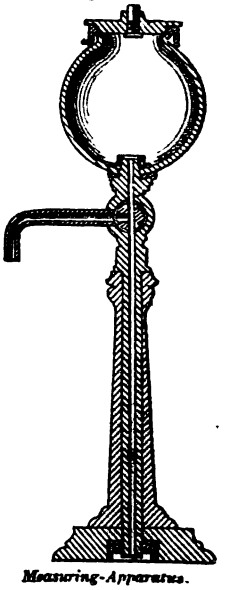


Adjustable Measure.

Fig. 3095 is a measure with a bottom adjustable for different quantities. Spring catches on the bottom are operated by projections beneath, and enter notches in the sides of the cylinder at the proper points.

The gallon, quart, and pint are used for small measures of capacity. For weight we have, foolishly enough, several kinds of pounds of varying weight, the avoirdupois weighing 7,000 grains and divided into 16 ounces, and the ounce into 16 drams; the Troy pound of 5,760 grains divided into 12 ounces, the ounce into 20 pennyweights, and the pennyweight into 24 grains; the apothecaries' weight of 5,760 grains, divided into 12 ounces, the ounce into 8 drams, the dram into 3 scruples, and the scruple into 20 grains. The grain is the constant. See books on weights and measures, Haswell's "Handbook," and the specific index under METERS.

Fig 3096.



Measuring-Apparatus.

Among measuring devices are those known as *rules, sticks, tapes, lines*, etc. See also lists under GAGES, CALCULATING AND MEASURING INSTRUMENTS, DRAFTING AND MATHEMATICAL INSTRUMENTS.

Besides these may be simply mentioned *measuring faucets, funnels, pumps, board, cloth, lumber, surveyor's, tailor's, tire measures*, etc. See also succeeding articles, which describe measuring attachments for tanks, stills, casks, faucets, funnels, tires, etc.

2. (*Joinery.*) *Single measure* is square on both sides; *double measure* molded on

Digitized by Google

both sides; *measure and a half*, molded on one side, square on the other.

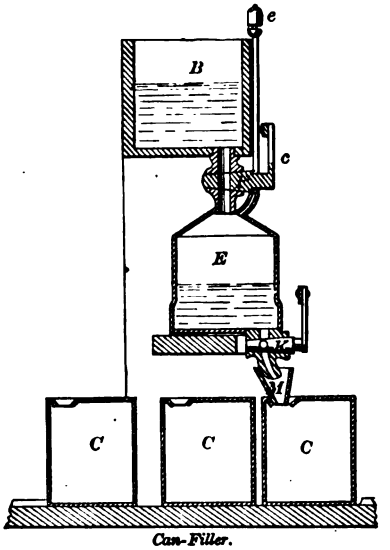
3. (*Mining.*) A stratum or bed of coal.

4. (*Printing.*) *a.* The space in a composing-stick between the end and the slide. The length of a line.

b. The width of a column or of a page of type.

Meas'ur-ing-ap'pa-ra'tus. A device for measuring liquid in transitu. In Fig. 3096 the liquid flows into the measuring-globe, and by the rotation of the faucet is shut off from the induction-pipe and drawn off by the eduction-faucet. The globe is of known capacity, and the successive fillings and emptyings are counted.

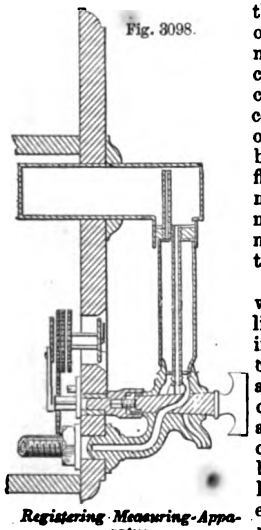
Fig. 3097.



Can-Filler.

Fig. 3097 is a device for filling cans of given capacity. A number of cans, *C C C*, stand in a row, and over each is a chamber *E* which has a measured capacity. The plug-levers *c* of the fill-cocks of the series of measures *E* are connected together so that one movement opens or closes them simultaneously. The discharge-cocks *K* are similarly connected. Whistles connected with the tops of the measures indicate by the passage of air the flow of liquid into the measures. Pivoted funnels *M* gravitate to the mouths of the cans on their presentation.

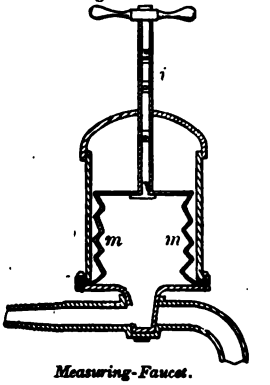
Fig. 3098.



Registering Measuring-Apparatus.

In Fig. 3098 the two-way cock allows the liquor to flow alternately into and from the receiver and connects with a register. The receiver communicates with an air-chamber above it, the compression of the air balancing the weight of liquor and assisting to empty the receiver. A pipe communicates from the air-chamber to the supply-pipe to keep up the equilibrium by discharging any liquor which had entered the air-chamber when the pressure of liquor was at its maximum.

Fig. 3099.



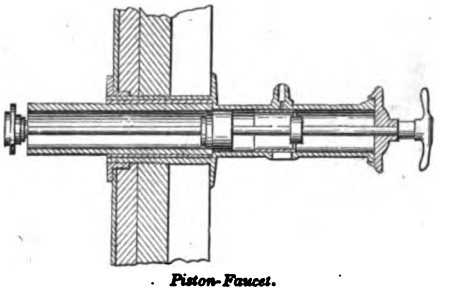
Measuring-Faucet.

Meas'ur-ing-chain. The SURVEYOR'S-CHAIN (which see).

Meas'ur-ing-fau'cet. A faucet which measures the amount of passing liquid. There are several types. In Fig. 3099, the chamber being in a position to form communication between the vessel to be drawn from and the interior of the flexible tube, the disk is raised so as to draw liquid into said tube, — the discharge end of the faucet being, in the mean time, closed. The chamber is then turned so as to reverse the direction of the tube's communication with the faucet, and, the disk being then depressed, the measured liquid is ejected from the tube through the outer end of the faucet. For drawing off a less quantity than the capacity of the flexible chamber *m m*, the stem *i* is graduated.

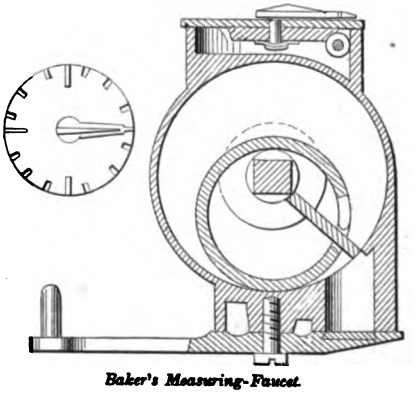
Another variety has a piston working in a glass cylinder of known capacity. The liquid included between the valve and piston is drawn forward to the discharge opening, which is unstopped by the motion of the inner sleeve.

Fig. 3100.



Piston-Faucet.

Fig. 3101.

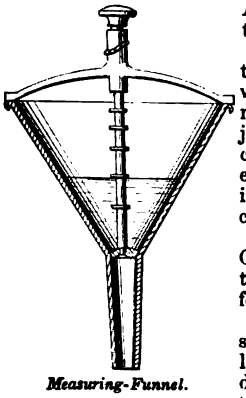


Baker's Measuring-Faucet.

Digitized by Google

Baker's measuring faucet is on the principle of the rotary pump. An eccentric in the chamber is revolved by a crank, and the sliding piston ejects at each revolution the known contents of the cylinder. A register on top keeps tally of the revolutions.

Fig. 3102.



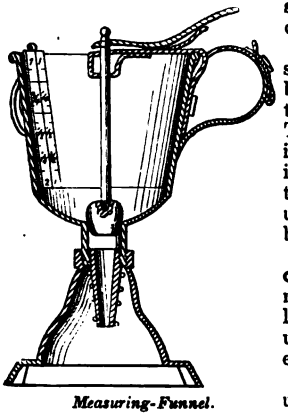
Measuring-Funnel.

In another variety of this type, two cylinders work together, in the manner of Root's blower, projections on one entering cavities in the other, and each being packed against its own portion of the twin cylinder inclosing the two.

Meas'ur-ing-fun'nel. One having graduations to indicate quantity at different degrees of fullness.

Fig. 3102 has a valve-stem, on which, at calculated distances, are small disks indicating the quantity of liquid in the funnel at different levels. To lift or close the valve, the stem is turned by its handle, when a projection from it ascends or descends an inclined slot in the collar ascending from the bar.

Fig. 3103.



Measuring-Funnel.

In Fig. 3103, the scale is marked on a bent strip which clips the side of the vessel. The stem of the valve is guided in a projecting bridge-piece, and the measure stands upon a detachable base.

Meas'ur-ing-ma-chine'. An instrument for ascertaining length, or "end measurement," with great exactness.

Whitworth's measuring-machine, which can be graduated to the one-millionth part of an inch, is shown in Fig. 3104, at *A B C*.

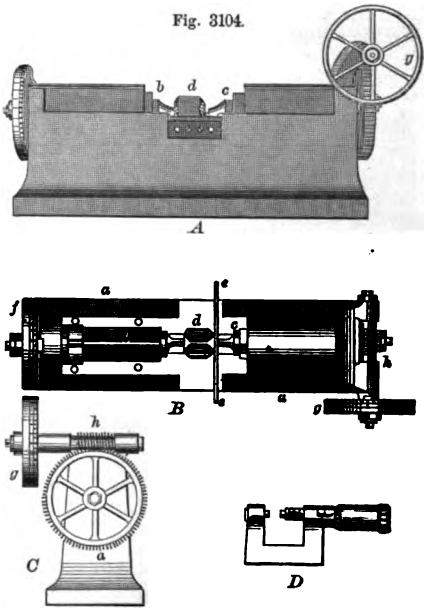
The solid bed of the machine *a* is carried up at the ends so as to form two head-stocks. A V-shaped groove runs from one of the head-stocks to the other, and in this groove the square bars *b* and *c* are laid, as is also the standard of the bar *d*, of which the length is to be tested. The sides of the groove and of the bars are worked up to as true a plane as possible, and are kept at right angles to each other. The ends of the bars are also made square with their sides and brought to true planes, the ends being turned down to present circular instead of square faces.

Through each head-stock runs an accurately pitched micrometer-screw, by which *b* and *c* are driven along the groove. The screw on the side of *b* has exactly 20 threads to the inch, and is turned by the wheel *f*, the circumference of which is divided into 250 parts. Consequently, by turning the wheel forward one division, the bar is moved one five-thousandth of an inch.

The other screw has a similar thread, is driven by a worm-wheel of 200 teeth, into which gears a tangent screw *h*, having fixed upon its stem the graduated wheel *g*. The circumference of this wheel being also divided into 250 parts, a movement of one division corresponds to a traverse of $\frac{1}{20} \times \frac{1}{200} \times \frac{1}{250}$ = one millionth of an inch on the part of the bar *c*. Fixed pointers enable the exact movement of wheels *f* or *g* to be read off, so that this extremely minute difference in the length of any bars may be detected, provided the micrometer screws exert an equal pressure in every case.

This equality of pressure is secured by a very sim-

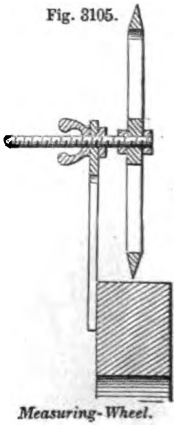
Fig. 3104.



Measuring-Machine.

ple and beautiful arrangement. Between one extremity of the bar under comparison and the sliding-bar a small steel piece, with true parallel sides, is introduced. This piece is called the *feeler*, and its ends *e e* rest upon two supports on the sides of the bed. When little or no pressure is exerted on the bar *d*, the feeler falls back of its own weight if one of its ends be raised. A very slight pressure prevents this falling back, and the friction between this piece and the ends of the bars becomes a very delicate measure of the pressure to which it is subjected.

Fig. 3105.



Measuring-Wheel.

D, Fig. 3104, is a pocket-instrument, made to measure to one thousandth of an inch. The screw has 50 threads to an inch, the head having 20 divisions on the circumference. Consequently, a turn of the head through one division advances the screw $\frac{1}{20} \times \frac{1}{50} = \frac{1}{1000}$ of an inch.

Meas'ur-ing-pump. One in which the piston operates in a chamber of known capacity, a train of wheels and dial registering the pulsations of the piston.

Meas'ur-ing-tape. A tape divided into inches and fractions, and coiled around an axis in a box; retracted by a spring or winding handle.

Digitized by Google

Paine's American steel-tape measure is made of a steel ribbon, divided into yards, feet, links, or some other unit of measurement. The metallic ribbon has many advantages over that made of linen, in respect of its not being affected by moisture, or liable to extension of length by tension. Measuring-tapes are frequently accompanied by registering devices, the axis of the tape being connected to a set of gearing and pointers in the manner described under ARITHMOMETER (which see). See Paine's patents of 1860.

Tape-measures are specifically made for surveying, lumber measuring, cloth measuring, etc.

Meas'ur-ing-wheel. 1. One for measuring the circumference of a carriage-wheel, in order to find the length of tire required. A *circumferentor*. The small wheel has a known circumferential measurement, and is divided into inches and fractions. The result is told in numbers of revolutions and fraction of a revolution expressed in inches. In the illustration the wheel has a guide which traverses against the side of the rim and assists in maintaining the measuring-wheel in place. A *circumferentor*; a *tire-measurer*.

2. An ODOMETER (which see).

Meat-bis'cuit. A portable, concentrated preparation of meat, pounded, dried, mixed with meal, and baked. It was originally introduced by Mr. Gail Borden.

For making meat-biscuits, good beef is selected and boiled by steam until all the nutritive qualities are extracted. The liquor is strained, allowed to settle, and then evaporated by heat to the consistence of thick treacle; the fat is skimmed off as it rises. While the liquor is yet hot, flour is added to it, and both are kneaded up into a stiff dough, which may then be rolled, pressed, made into biscuits, and baked. The biscuits are either kept whole or are ground to powder, and are preserved in air-tight cases. For making into soup, the powdered biscuit is mixed with hot water and boiled, with the addition of salt and other condiments.

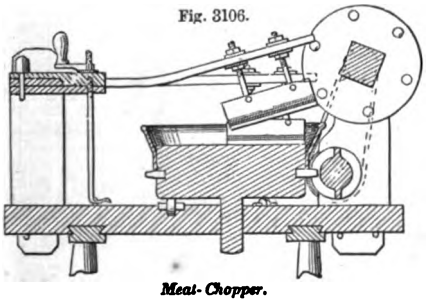
The process of Carr and Lucop consists in pulverizing plain biscuit, mixing this powder with the extract of meat, and subjecting the compound to a heavy pressure or stamping it in molds.

The same method is employed in making biscuit with preserved fruits or any material liable to be injured by the heat of the oven.

Cheese-biscuit are made by inclosing the powdered cheese between two layers of powdered biscuit, and pressing the whole in a mold.

Meat-chop'per. A machine for mincing meat for sausage or for stewing. Among the many varieties may be cited the kind having vertical knives

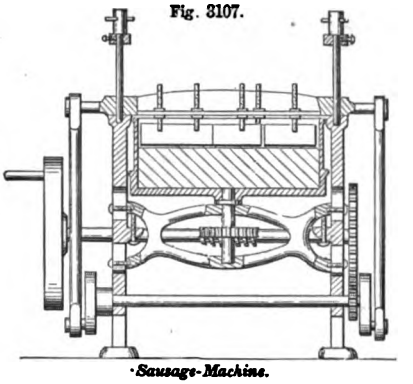
Fig. 3106.



Meat-Chopper.

on flexible or weighted stocks. In Fig. 3106, the block rotates by the engagement of its sprockets with the worm on the shaft. The cleavers are attached

Fig. 3107.

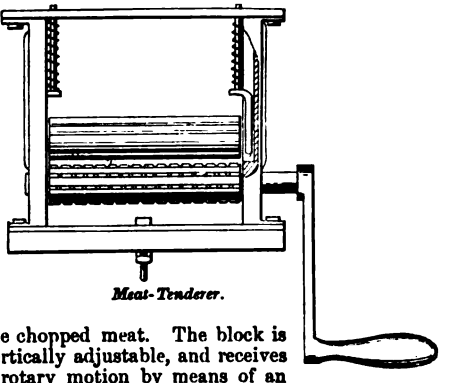


Sausage-Machine.

to spring arms, and the force of the blow is regulated by a nut on the pivoted block, in which their shanks are clamped.

Fig. 3107 has a revolving block, but the knives, instead of snapping, are simply reciprocated in guides by means of pitmans and gearing. The guides are removable to allow the cutter-heads to be inverted, to clean or sharpen the knives, and to remove

Fig. 3108.



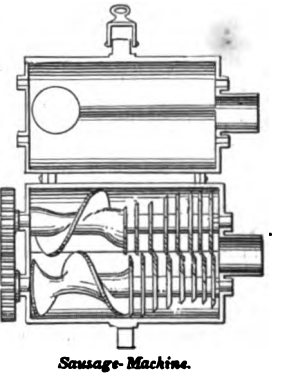
Meat-Tenderer.

the chopped meat. The block is vertically adjustable, and receives a rotary motion by means of an endless screw and worm-wheel. See also MEAT-CUTTER; SAUSAGE-MACHINE.

Meat-crush'er. A pair of rollers for tendering steak. In the example, one roller has circumferential and the other longitudinal corrugations.

Meat-cut'ter. A machine for mincing flesh. A *sausage-machine*. In Fig. 3109, the two sections of the shell have smooth surfaces and are hinged together. The cutters are interchangeable, and are placed in spiral relation upon the shaft, and with intervening washers, which regulate their distance apart. The worm on the shaft forces the meat between the knives, which make a shear-cut against each other, and so to the exit.

Fig. 3109.

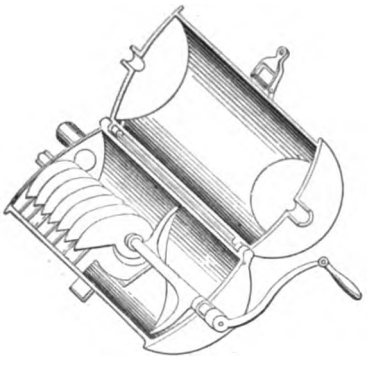


Sausage-Machine.

Digitized by Google

In Fig. 3110 there is but a single system of moving cutters, which pass between knives attached to

Fig. 3110.

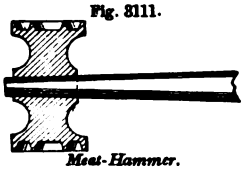


Meat-Cutter.

the shell, while the meat is forced forward by the screw, as in the former case.

Meat-ham'mer. A maul with a notched or ridged face, to pound meat and render it more tender, as in the example, where the hammer-face has angular projections.

Fig. 3111.



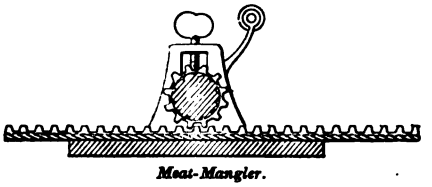
Meat-Hammer.

Meat-hook. One in a larder or on a butcher's stall, to hang joints of meat.

Meat-knife. One the haft of whose blade passes through the handle, which consists of two pieces known as *scales* and secured by rivets.

Meat-man'gler. A device for tendering steak.

Fig. 3112.



Meat-Mangler.

The roller has a roughened surface counterpart to that of the bed to which it communicates motion.

Meat, Pres'er-va'tion of. Mechanical or chemical appliances to prevent decay of animal food have been in use from the earliest ages. Freezing, salting, and drying meat for future use are older than history.

Freezing is perhaps the simplest and quickest mode of preservation, and answers well in cold climates. Attempts have been made to freeze meat by artificial means in countries where live stock is plenty, as in Australia and Texas, and transport it in a frozen state to market. Several hundred tons of beef were packed in a refrigerating ship in Australia, but the attempt to transport it to England failed because of the exhaustion of the supply of ice.

Dried meat is usually prepared by cutting in thin strips and hanging in the sun. The American Indians pound their meat in wooden mortars until it forms a paste, which is mixed with fat and dried in blocks. It is then called *pemmican*, is quite nutritious, and is used in large quantities by Arctic voyagers.

Artificially dried meat is usually more or less smoked in preservation. The pyroligneous acid and creosote contained in peat or wood smoke coagulates albumen, with which it comes in contact. So-called *smoked-meat* generally owes its preservation to the salt with which it is saturated, the creosote only penetrating a short distance.

Meat is salted either in a pickle or brine, or dry-salted, which latter way is more expensive, but retains more of the nutritive qualities of the meat.

A mode of salting by wholesale is by an injection of brine and saltpeter into the heart of the animal immediately after it is killed. The brine penetrates the whole vascular system, expelling the blood, and flows from the right ventricle in a clear stream.

The first attempt to preserve meat by canning in air-tight vessels was made by M. Appert, at Paris, 1810. His process consisted in partly cooking the meat, placing it in a glass vessel in a bath of chloride of calcium, and then hermetically sealing it.

The modern process of putting up "preserved meats" is substantially as follows:—

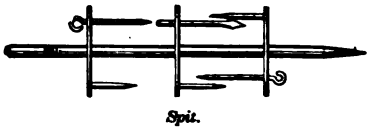
The meat is placed in the can, which is then filled up with soup. A cover pierced with a small hole is then soldered on. The can is placed in a bath of a solution of chloride of calcium, which boils at about 320° Fah. When the generated steam has expelled the air, a drop of solder closes the hole. When the can cools, the pressure of the air resulting from the condensation of steam bends in the heads, which become concave. The cans are then placed in a proof-chamber, and exposed to a tropical heat of say 120° Fah., as high as they will be apt to encounter. Taint in the meat, or imperfect closure, manifests itself by the bulging out of the heads.

Meat-saw. A saw with a thin blade strained in an iron frame and used by butchers.

Meat-screen. A metallic screen placed behind roasting meat to reflect back the heat of the fire.

Meat-spit. One for holding a roasting joint

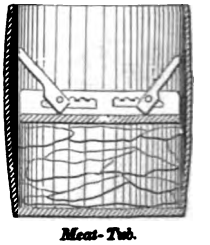
Fig. 3113.



Spit.

while turning in front of the fire. In the example, the spit has sliding skewer plates which have fixed and removable skewers. The spit is oblong in section, to prevent the skewer plates from turning thereon.

Fig. 3114.



Meat-Tub.

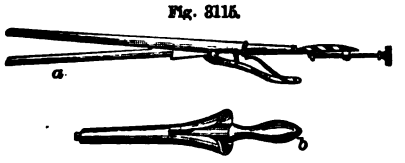
Meat-tub. One for holding pickled meat. The example has a follower to keep the pieces below the surface of the brine. The cover lies upon the meat in the barrel, and is kept down by the engagement of the points of the pivoted arms with the inside of the barrel.

Me-a'tus-knife. A small knife with a triangular concealed blade in a long thin shaft; used in operations in the meatus auditorius, such as obliterating strictures, opening pustules, scarifying, removing polypi, etc.

a, meatus-knife. *b*, meatus-cope.

Digitized by Google

Fig. 3115.



Meatus-Knife and Meatuscope.

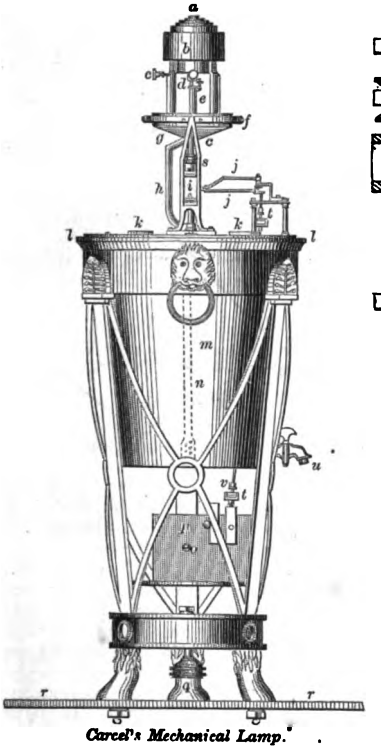
Me-a'tus-cope. A urethra speculum.

Me-chan'i-cal Broom. A sweeping-machine, usually propelled by horses, and having revolving brooms actuated by the supporting wheels, and delivering the dust and mud into the box of the wagon. See STREET-SWEEPING MACHINE.

Me-chan'i-cal Lamp. Another name for Carcel's clock-work lamp, in which the oil is pumped from a lower reservoir to the wick-tube by means of clock-work, so as to furnish a supply exceeding that consumed by the wick, the surplus flowing back outside of the burner. The object is to afford equal and ample supply of oil to the flame.

A spiral spring and piston in the reservoir have been used as a substitute for the clock-work pump, which is objectionable on account of its expensiveness for domestic uses, but is valuable in important situations, such as lighthouses.

Fig. 3116.



Carcel's Mechanical Lamp.

James Watt, in a letter to Argand, August 8, 1787, gave sketches of proposed lamps with oil-pumps worked by clock-work. See "Engineer," Vol. I. p. 37.

Fig. 3116 represents a mechanical lamp adapted for dioptric lights of the first order.

a, wick-holder.
b, glass-holder.
c, screw to rack for raising wick.
d, rack for raising wick.
e, pipe supplying oil to wick.
f, collar supporting burners.
g, drip-cup.
h, return-pipe for overflowing oil.
i, valve-box.
j, crank-rods for working leathern valves.
k, hinge of lid.
l, lid of cistern.
m, oil-cistern.
n, suction-pipe.
o, winding-arbor for clock-work.
p, box for clock-work.
q, screw for adjusting level of burner
r, service-table.
s, coupling-screw for oil-tube.
t, universal joints for connecting-rod.
u, cock for emptying cistern.
v, connecting-rod for cranks.

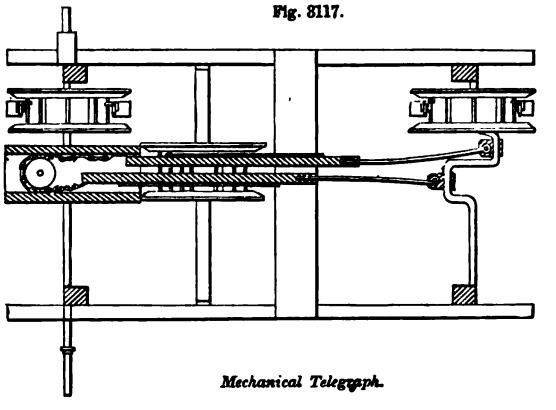
Me-chan'i-cal Leech. See LEECH, ARTIFICIAL.

Me-chan'i-cal Pi'geon. A flying object forming a substitute for a pigeon in shooting-matches. See PIGEON.

Me-chan'i-cal Tel'e-graph. Another name for the automatic telegraph, in which a message represented by a series or succession of dots is passed beneath a key or stylus, so as to make and break the circuit by simply mechanically passing through.

In another apparatus of local use perhaps, but not susceptible of application to distant points, the apparatus has bell-cranks which stand at angles of 120° with each other; the crank of the shaft at one station is connected by rods with that of the other. Endless chains with lettered links pass around the wheels, correspondence being maintained between the two; one being actuated by an operator to bring given letters in series to a fixed point, the corresponding letters are brought by synchronous action to analogous position on the other to be viewed by the observer at that point.

Fig. 3117.



Mechanical Telegraph.

Me-chan'o-graph. One of a set of multiplied copies of an original, executed by means of a machine.

Mèche. (*Surgical.*) A bunch or pledget of charpie, cotton, or raw silk, for keeping open an ulcer or wound. Applied by an instrument known as a *porte-mèche.*

Mech'lin-lace. (*Fabric.*) A light Belgian lace with an hexagonal mesh; made of three flax threads, twisted and plaited to a perpendicular line, the pattern being worked in the net, and the plait-thread surrounding the flowers.

Me-com'e-ter. (*Surgical.*) A graduated instrument used at the Hospice de Maternité in Paris, to measure new-born infants.

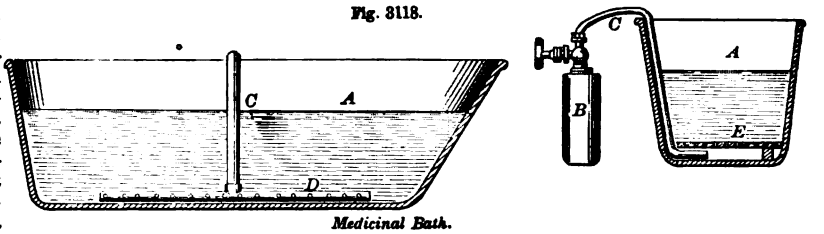
Med'al. An ancient or a memorial coin.

Me-dal'lic En-grav'ing. In this beautiful art the direction and distance of the lines are so modified as to give the appearance of a figure or object in relief. It is executed by machinery. The machines of M. Collas and Mr. Bate, as well as those of Asa

Digitized by Google

Spencer, Mr. Froude, and Mr. Saxon, are all improvements upon an apparatus described in a French work, the "Manuel de Tourneur," about 1814. This machine will give a good general idea of the construction of these machines, and its operation is as follows: —

Fig. 3118.



Medicinal Bath.

The medal and the copper on which the medal is to be engraved are fixed on two sliding plates at right angles to each other, and so connected that when the plate on which the metal is fixed is raised vertically by a screw, the side holding the copper plate is advanced by an equal quantity in the horizontal direction. The medal is fixed on the vertical slide, with its face toward the copper plate and a little above it. A bar, terminating at one end in a tracing-point and at the other in a short arm at right angles with the bar, and holding a diamond-point, is placed horizontally above the copper, so that the tracing-point shall touch the medal to which the bar is perpendicular, and the diamond-point shall touch the copper plate to which the arm is perpendicular. Under this arrangement, the bar being supposed to move parallel to itself, and consequently to the copper, if the tracing-point pass over a flat part of the medal, the diamond-point will draw a straight line of equal length upon the copper; but if the tracing-point pass over any projecting part of the medal, the deviation from the straight line by the diamond-point will be exactly equal to the elevation of the corresponding point of the medal above the rest of the surface. Thus, by the transit of this tracing-point over any line upon the medal, the diamond will draw upon the copper a section of the medal through the line. A screw is attached to the apparatus, so that if the medal be raised a very small quantity by the screw, the copper plate will be advanced by the same quantity, and thus a new line of section may be drawn. By continuing this process, the series of sectional lines upon the copper produces the representation of the medal on a plane, the outline and the form of the figure arising from the sinuosities of the lines and from their greater or less proximity.

Me-dal'lion. 1. A large medal.

2. A carved, molded, cast, or stamped circular ornamental work.

Med'al-ma-chine'. A machine for making copies of medals and raised or sunk works on a scale larger or smaller than the original. It comprises adjustable frames on the pantograph principle for carrying tracers which pass over the face of the original, and mandrels in which the various cutters for producing the copy are inserted. It operates upon the CARVING-MACHINE (which see).

Med'i-cat-or. (*Surgical.*) A spoon, syringe, or insufflator, for directing a medicament into or upon a deeply seated part.

Me-dic'i-nal Cup. One for the administration of medicine to persons prostrated by sickness or injury. Some such cups have graduations to indicate quantity; or a tubular handle through which the liquid may be conducted to the mouth without spilling; or the lip of the cup has a little hood which constitutes an aperture through which the liquid is poured. Another cup resembles a pipette, discharging at the lower opening when the finger is temporarily withdrawn from the orifice in the upper end.

A medicinal cup of a former age was of antimony, rendering emetic a dose of wine allowed to stand therein.

Me-dic'i-nal Bath. In the apparatus, Fig. 3118, the medicinal vapors are forced, by their own pressure or otherwise, from the reservoir *B* through the pipe *C*, and, entering the bath-tub *A* beneath the perforated false bottom *E*, through the longitudinal perforated pipe *D*, pass upward in bubbles.

Med'i-cine-spoon. A spoon for the administration of medicines. As in the example, it may

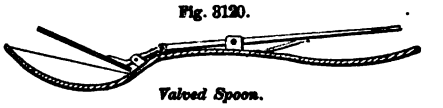
Fig. 3119.

Medicinal Spoon.

consist of a common teaspoon, provided with an adjustable lid which covers the bowl, leaving a small aperture at the tip, whereby the contents escape when the spoon is introduced into the mouth. The spoon is filled at the aperture near the handle.

In another form the cover is connected to a compound lever, which is influenced by a spring to close it. The cover is depressed by the lever. A portion

Fig. 3120.



Valved Spoon.

at the point of the spoon is left uncovered to allow the exit of the medicine.

Me'di-um. A size of drawing and writing paper between demy and royal, measuring 22¼ × 17¼ inches, and weighing 20 to 34 pounds to the ream.

Of printing-paper, 19 × 24 inches.

Med'ley. (*Fabric.*) Cloth woven from wool dyed of various colors and spun. Technically, blue and black are excluded. First made in 1614.

Meer'schaum. Meerschaum (foam of the sea), a superior species of white clay, chiefly consisting of silicate of magnesia, and dug mostly in the peninsula of Natoli, Asia Minor. It is sent to market in irregular blocks of different sizes, the latter fixing the price, which is much higher in proportion for large lumps than for small ones. The Turkish government owns the mine and stipulates the quotations according to the demand, which generally exceeds the supply.

In manufacturing pipes, the lumps are cut into shape with a knife, after having been lightly wetted; the bowls are then carefully rubbed to obtain a clear, smooth surface, and afterward boiled either in pure wax, or wax, oil, and fats, the latter effecting a yellow hue, and facilitating the coloring.

Digitized by Google

Meet'ing-post. (*Hydraulic Engineering.*) That stile of a canal-lock gate which meets the corresponding stile of the other gate at the midwidth of the bay. See LOCK-GATE.

Me-gal-eth'o-scope. An improved form of stereoscope invented by Ponti, in which the photograph is considerably magnified and an increased appearance of sphericity obtained.

It is so arranged that the object may be viewed by direct or reflected sunlight, or by artificial light. — Prac. Mech. Jour., 3d series, Vol. III. p. 111.

Me-gam'e-ter. 1. An instrument for determining the longitude by observation of the stars.

2. A micrometer.

Meg'a-scope. (*Optics.*) 1. A solar microscope in which the objects are opaque and illuminated in front by reflecting mirrors.

2. An optical instrument for exhibiting an object on a large scale.

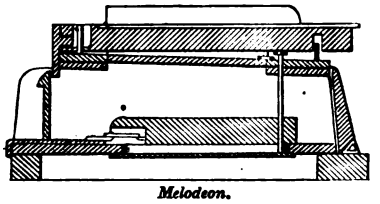
Me-gass'. Refuse sugar-cane from which the juice has been expressed. See BAGASSE.

Meir. (Eng. *local.*) Thirty-two yards of ground in a vein of ore.

Me-lan'o-type. (*Photography.*) Sometimes written *melainotype*. A process which takes its name from the *black* ground of varnished sheet-iron supporting the collodion which receives the picture. Also called FERROTYPE (which see).

Me-lo'de-on. (*Music.*) A wind-instrument with a row of reeds and operated by keys. The instrument has a bellows which formerly blew air through the reeds; but Carhart in 1846 patented the feature of drawing air through the reeds by suction bellows: he also invented machines to make, rivet, and plane the reeds; also the *tube board* to hold

Fig. 3121.



Melodeon.

the reeds, a machine to rivet the reeds to the blocks, and one for cutting the cells in the reed-board. Pressure on the key drives down the pin and the valve, allowing passage to the air. The principle is the same as the accordeon. *Flutina, parlor-organ, harmonium, seraphine,* are all names of instruments of this kind.

Mel'o-type. (*Photography.*) A process in photography in which a dark chamber is not used, and the pictures are developed at a subsequent convenient time.

Melt'ing-fur'nace. A foundry cupola, or a glass-maker's furnace.

Melt'ing-point. That point of the thermometer at which a substance becomes fused. See FUSING-POINT; THERMOMETER. See also p. 1422.

Mel'ton. (*Fabric.*) A kind of broadcloth for coating.

Me-nis'cus. A lens convex on one side and concave on the other. See LENS.

The concave side has a curve of greater radius than the convex side, and the lens is thicker in the middle than elsewhere.

In this respect the meniscus differs from the *concavo-convex lens*, whose convex face has a curve of greater radius.

Men's Har'ness. An arrangement by which men are attached to a gun-carriage which is to be moved but a short distance or where animal power cannot be employed. It consists of a rope 18 feet long and 4 inches in circumference, having a thimble at one end and a thimble and hook at the other. Ten leather loops are fixed in pairs to the rope, 5 on each side. These are of sufficient size to allow a man to pass his body through them, the strain of the draft coming on his chest.

Men'stru-um. A solvent, such as water, alcohol, ether, acids, oils, etc.

Men'tal. A basket made water-tight, and having four ropes attached, by which two men dip water

Fig. 3122.

Mental.

from a stream or cistern and discharge it into a trench for irrigation.

Mer-ca'tor-chart. A mode of projection invented by Gerald Mercator, in which the meridians and parallels are straight and parallel lines. The meridians are equidistant, but the distance between the parallels increases from the equator towards either pole. See CHART; MAP.

Mer'chant-i'ron. Bar-iron.

Mer'chant-rolls. Finishing rolls of a rolling-mill.

Mer'chant-train. A train of rolls with grooves of varying sizes and shapes, which reduce the reheated *puddle-bars* to bar-iron of merchantable form.

Mer-cu'ri-al Bath. Used in the pneumatic trough in collecting such gases as are largely absorbed by water.

Mer-cu'ri-al Gage. The pressure-gage in which the steam acts upon a body of mercury and raises a column in a glass tube.

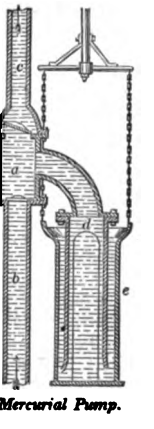
Mer-cu'ri-al Horn-ore. Horn quicksilver.

Mer-cu'ri-al Lev'el. A form of level in which mercury is used.

Mer-cu'ri-al Pen'du-lum. A compensation pendulum invented by Graham of London, 1700.

A jar of mercury is used for the *bob* or weight. As the pendulum expands the mercury rises, and by the rise of its center of gravity compensates for the other inequality. See PENDULUM.

Fig. 3123.



Mercurial Pump.

Mer-cu'ri-al Pump. A pump invented by Haskins in 1720, in which a column of mercury acts as plunger and piston packing.

Fig. 3123 shows a pump of this form. *a* is the chamber of the pump, with a valve at each end opening upwardly. *b* is the suction-pipe, and *c* the outlet. A bent tube connects chamber *a* with cylinder *d*, open at bottom and surrounded by a large cylinder or cup

Digitized by Google

e filled with mercury, or with a wooden core to save a portion of the mercury, as in the illustration.

If now the cup *e* be lowered, the tendency will be to produce a vacuum in chamber *a*, which will be immediately filled with water from the inlet pipe. By raising cup *e* the water will be expelled through *c*.

Mer-cu'ri-al Ther-mom'e-ter. A thermometer tube filled with mercury, in contradistinction to a spirit, air, or metallic thermometer.

Mer'cu-ry. Equivalent, 100; symbol, *Hg.*; specific gravity, 13.59; fusing-point, −39° Fah. Fluid at ordinary temperatures.

Occurs principally as a sulphide (*cinnabar*). It is a brilliant, silver-white, heavy metal. Distills at 662° Fah.

It is used in medicine associated with chalk (*blue pill*) and lard (*mercurial ointment*).

The chloride is corrosive sublimate, used in the Kyan wood-preserving process; and the sub-chloride is calomel.

The metal is used in philosophical instruments, — barometers, thermometers, etc.

An alloy of mercury with another metal is called an AMALGAM (which see).

Mercury is used to extract gold or silver from the earthy and baser metallic constituents of these ores; amalgamating with the gold and silver when brought into contact therewith. See AMALGAMATOR; SILVER-MILL, etc.

An amalgam of tin, 4, mercury, 1, is used to *silver* looking-glasses.

Many metals amalgamate with mercury, and others do not.

Added to certain fusible alloys it reduces their point of fusion below the heat of boiling water. See ALLOY, p. 62.

The ore of mercury — chiefly cinnabar, the sulphide of mercury — is broken, sifted, and crushed. It is then heated in a furnace with lime, iron, or some other agent which combines with the sulphur.

The mercury is vaporized, passes off, and is condensed into a metallic form. It is purified by filtration and stored in iron bottles.

Quicksilver has been mined from time immemorial in Spain at Almaden in the province of La Mancha. "Dioscorides separated mercury from cinnabar." (HUMBOLDT.) Pliny states that 700,000 pounds (of cinnabar?) were received yearly from that source, and that the Greeks received it from thence 800 years previously to the date at which he wrote (A. D. 70). (See AMALGAM.) It is now mined extensively at Idria, in the Schiefergebirge, and is found in Hungary, many parts of Germany, in China, Japan, Mexico, Honduras, Columbia, Peru, and California.

The modes of obtaining mercury by the decomposition and distillation of cinnabar have been very imperfect and wasteful; and even at this day, with all the advantages of skill and capital, the actual product is but a small proportion of the amount obtained by a careful analysis. It is understood that in Europe the ores are heated upon open arches and the vapors condensed within brick chambers.

For detailed description of the process and apparatus, we must refer the reader to Ure's Dictionary and chemical treatises, as the subject is not so clearly within the scope of this work that it can be treated at any length.

The extensive quicksilver mine of New Almaden is twelve miles from San José in California, and has had the benefit of energy, skill, and capital in its development. A good description of the place and the works was written in 1857, and given in Harper's "Magazine," June, 1863. Changes may have since taken place. The mode of mining and breaking into pieces suitable for the furnace has nothing peculiar to offer, but the condensing-furnaces are worthy of notice. They are sixteen in number, arranged side by side, and extend a distance of several hundred feet beneath a spacious roof. They stand 8 feet apart, are 40 feet in length, 10 in hight, and 8 in breadth. The ore is cleaned, broken, and dumped into the receiving-chamber, which is next to the furnace, and holds 7 tons of ore. The cover being luted on, the sublimated vapors pass by a circuitous route through 12 chambers successively, the connecting apertures being alternately at the tops and bottoms of the division walls. The mercury condensed in each chamber passes through small holes in the side to a covered trough on the outside, which conducts it to a reservoir, whence it is dipped into iron flasks which receive a charge of 75 pounds, and are then closed by a screw cap. While passing from the last of the twelve to the stack, the vapor is brought into contact with a pan of water, which still farther condenses escaping fumes.

Mer'cu-ry-fur'nace. A furnace in which cinnabar is treated for the production of mercury.

The localities yielding the sulphide of mercury are not numerous. The Almaden mines of Spain were known to the Greeks 700 B. C., and were celebrated in the time of Pliny. The mines of Idria, the Palatinate, and of New Almaden in California, are extensive and rich. The ore is also found in Peru, China, Hungary, Sweden, Japan, and Chili.

In the furnace the ore is subjected to distillation in retorts which lead to condensing-chambers, or the blocks of ore are roasted in a furnace, the whole volatile results of the furnace passing with the metalliferous fumes to a series of condensing-chambers. See CONDENSER. See previous article.

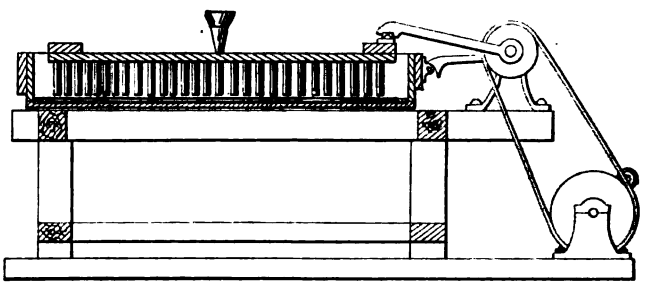
The latter is the plan adopted at Idria in Austria, the former in Bavaria and California. Dr. Ure's retort-furnace, erected at Landsberg in Bavaria, resembles the apparatus for the distillation of coal-gas.

In Spain, the old Buytrone or Aludel furnace is still adhered to. See ALUDEL.

Mer'cu-ry-gath'er-er. (*Metallurgy.*) A stirring apparatus in which *floured* quicksilver, which has been rendered what is technically known as *sick*, is gathered together. See AMALGAM.

Mercury which is *floured* is in a sort of powdery condition, the particles being coated with sulphur from the pyrites or from other cause; and the object

Fig. 3124.



Quicksilver-Gatherer.

Digitized by Google

of the mechanical agitation and rubbing, in the mercury-gatherer, is to cause the globules of mercury to coalesce and resume the fluid condition.

Me-rid'i-an. A great circle supposed to pass through both poles, and the zenith and nadir of a given place.

Me-rid'i-an-cir'cle. 1. A transit instrument with a graduated circle securely fastened at right angles to the horizontal axis and turning with it.

The meridian circle in the National Observatory of Washington was made by Ertel and Son, of Munich. Its object-glass has an aperture of 4½ inches, with a focal distance of 58 inches. This instrument is provided with a circle 30 inches in diameter, divided into arcs of 3′, and reads by four micrometers to single seconds.

2. The altitude circle of a globe.

Me-ri'no. (*Fabric.*) A fine, French, woolen goods, so named as being made of the wool of the merino sheep. It is a lady's dress goods, all wool, and twilled on both sides.

The Merino variety of sheep is a native of Spain, which country was celebrated for its wool in the time of Pliny.

The greater number of the sheep of Spain belong to the *mesta*, or merino corporation, which has about 5,000,000 sheep in flocks of 10,000 each. Each flock has an officer, 50 shepherds, and 50 dogs.

In summer, the sheep feed upon the elevated lands of Biscay, Navarre, and Arragon, and toward winter are driven southward to the fertile plains of New Castile, Andalusia, and Estramadura. The lambs come in January, and shearing commences the 1st of May, being carried on in houses where the flocks of sheep are folded on their northern march. 125 men shear 1,000 ewes per day, 50 weathers per man being considered a day's work. The ewes yield from 4 to 5 pounds of wool, the weathers from 7 to 8. The wool of each sheep is sorted into four varieties.

The carcass is but little esteemed.

The institution of the *mesta* dates from the time of the plague in 1350, when whole provinces were nearly depopulated and vast estates became ownerless. The proprietors of neighboring estates combined to throw the unoccupied tracts into a common pasture on which they herded sheep according to an agreed ratio.

Free passage is allowed to the flocks through the cultivated territories, and great hardship results. The power of this tyrannical corporation was somewhat reduced by the French, during their temporary occupancy of the country, 1808–12; a better legacy than any left by the succeeding English occupation, which was all in the interest of aristocracy and monopoly.

The merinos are now kept in immense numbers in Australia and Van Dieman's Land.

Turdetania, the country of the Guadalquiver, was famous for the quality of its wool in the time of Strabo, about the Christian era. A buck of fine quality was worth a talent (? Attic), equal to 1,180 dollars.

They were introduced into England in 1788.

Mer'kin. A mop for cleaning cannon.

Mer'lon. (*Fortification.*) The solid part of an embattled parapet, between two embrasures.

Mesh. 1. (*Gearing.*) Or *mash*. The engagement of the teeth of wheels with each other or with an adjacent object, as the rack, in a rack and pinion movement.

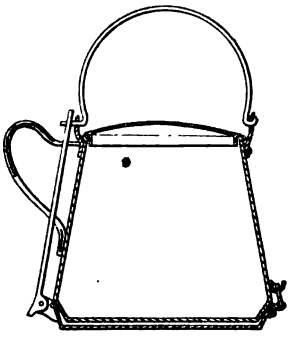
2. (*Netting.*) The loop made over a stick and engaging the loop in its vicinity.

Mesh-stick. (*Netting.*) A flat slat with rounded ends, used to form the mesh of nets, the loops being made over it and knotted on its edge.

Mes'sen-ger. (*Nautical.*) A rope passing from the capstan to the cable to which it is fastened by nippers. The winding of the messenger on the capstan hauls in the cable and the nippers are successively taken off that part of the cable that is approaching the capstan, and put upon that part which has just come inboard, through the *hawse*-hole.

Mess-kit. That portion of camp equipage consisting of cooking-utensils.

Fig. 3126.



Mess-Kit.

In the example, a frying-pan or griddle is conveniently attached to the bottom of the coffee-pot, by passing the handle of the pan up through a hole made in the handle of the coffee-pot, and then catching it by passing the end of the bail through a hole in its upper end, for convenience of transportation.

Met'a-car'pal Saw. (*Surgical Instruments.*) A narrow-bladed saw, about six inches long, used for dividing the bones of the fingers or middle hand or of the foot in amputation. In former times they were made with small bows: they are now straight, stiff-bladed, ground thinner on the back, to make them follow the cut easily; or thin-bladed with a stiffening *back*, which, after having cut to the depth of the blade, can be raised, when the blade will follow in the cut. See p. 92.

Met'al. 1. An elementary mineral substance possessing certain attributes, particularly the luster called metallic, by which it is distinguished from other inorganic productions. With few exceptions, metals possess considerable specific gravity, hardness, and cohesion, and require a high degree of heat to liquefy them. One, mercury, is liquid at ordinary temperatures, and a very few, as sodium and potassium, are lighter than water, which they decompose with such energy as to produce combustion.

The properties and qualities of metals by which distinctive descriptions are drawn are, —

Specific gravity, chemical equivalents, fusibility, hardness, brittleness, malleability, ductility, tenacity, elasticity, opacity of surface, sonorousness, color, lustrousness, odor, taste, dilatation by heat, specific heat, conductivity of heat, and also of electricity, magnetic or diamagnetic character.

The metals constitute about five sixths of the elementary bodies known to exist. They are distinguished by a peculiar luster, by their opacity, their power of conducting heat and electricity, and generally by a specific gravity considerably exceeding that of water.

Metals have been divided into five classes, principally depending upon their affinity for oxygen and the nature of the compounds formed by the union.

2. (*Civil Engineering.*) *a.* Broken stone for roads, according to the McAdam principle.

McAdam laid at most 10 inches of *metal* on a surface prepared by leveling and sloping.

Telford laid as a bottoming a compact layer 7 inches thick of pieces from 4 to 7 inches in dimension. Over this he spread the *metal*, which was made of a size to go through a ring 2½ inches in diameter.

This list does not include a number of rare metals which are not known out of the laboratory, and have no importance as yet in the arts.
The data, with the exception of the equivalents (old system), fusing-points, and tensile strength, are derived, with few exceptions, from Miller's **Chemistry**.
The conductivity for heat is that given by Calvert and Johnson. The results obtained by Wiedemann and Franz differ widely from these.
For electric conductivity, Mathiesson's results, which differ from those of Becquerel, are employed.
The fusing-points are those given by Professor P. H. Van der Weyde.

b. Broken stone around and beneath the wooden ties of a railway.

3. (*Glass.*) The technical name for the molten glass in order for blowing or casting.

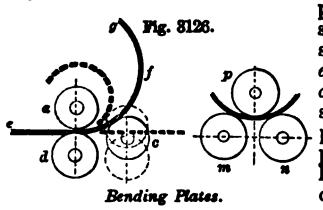
4. The effective power of the guns of a vessel expressed in the sum of the weights of the solid shot.

5. (*Founding.*) The workman's term for cast-iron.

Met'al-bend'ing Ma-chine'. Sheet-metal, such as tin-plate or boiler-iron, is bent into the cylindrical form by passing between rollers.

For the smaller descriptions of work the machine consists of two cylindrical rollers, *a* and *d*, geared to run together, and a third roller *c* which is capable of vertical adjustment. The metal is moved by the carrying rollers *a* and *d*, and, on striking the surface of the roller *c*, is bent up so as to pass over the same. As this bending occurs in an equal degree at every point of the sheet of metal, the result is that it assumes a circular sweep, the radius of which depends upon the position of *c*. In the central position, the sheet would assume the shape *e f g*, and, when *c* is more raised, say to the upper position, the plate would follow the dotted circle, the radius of which is much less. When the bending-cylinder *c* is thrown out of level, the sheet is thrown into a conical form.

Fig. 3126.



Bending Plates.

In the machine for bending plates the rollers *m n* are not necessarily in contact, and the regulation for different curvatures is by vertical adjustment of the upper roller *p*. The bending of sheet-metal for stove-pipes, chimneys, tin-ware, plow-mold boards, etc., is similar in principle.

Machinery is also used for bending skelps for tubes and gun-barrels; and for twisting strips into coils for gun-barrels.

Some articles are preferably bent into form by a stamping action.

Tubes are bent while filled with solder or resin, which allows them to assume a curve without puckering or disturbing the true circular section. By this mode the curved tubes of wind-instruments are made.

Met'al-fur'ni-ture. (*Printing.*) The metallic portion of the pieces used in filling up blanks, etc., in chases.

It includes reglet, side sticks, head and foot sticks, *quotation furniture* (hollow pieces of metal used to fill up blank spaces), and hollow quadrats. It is convenient to have reglet, etc. ready cut into lengths, varying from 18 to 120 or 130 ems. See FURNITURE.

Met'al-gage. One for determining the thickness of sheet-metal. A sheet-metal gage.

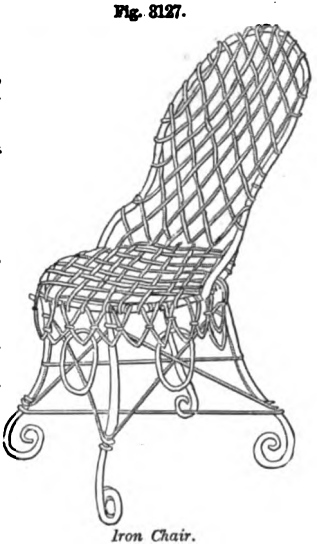
Met'al-ine. A compound for journal-boxes of metal, metallic oxide, organic matter, reduced to powder and compounded with wax, gum, or fatty matters. See JOURNAL-BOX.

Me-tal'lic Ba-rom'e-ter. One as contradistinguished from an instrument in which a fluid is employed. Also known as a *ho'osteric* barometer. Vidi invented the diaphragm form. (See ANEROID.) Bourdon invented the bent-tube form; a flattened, curved, exhausted tube, one end of which is fixed and the other geared to an index-pointer which traverses a graduated arc. Changes of pressure of the atmosphere affect the curvature of the tube, and so move the finger. See BOURDON BAROMETER.

Me-tal'lic Car'tridge. One in which the charge is contained in a metallic capsule, in contradistinction to the paper cartridge. See CARTRIDGE.

Me-tal'lic Chair. A chair of iron slats or wires interwoven, or of cast portions secured by rivets or screw-bolts.

Fig. 3127.



Iron Chair.

Used for parks, gardens, and auditoriums.

Me-tal'lic Dust. Grains of metal for giving a metallic luster to wall-paper, shell-work, lacquered ware, and for other purposes. It was first made by John Hautsch of Nuremberg (1595–1670). It is prepared by sifting the filings of different metals, washing them in a strong lye, and then placing them on a metallic plate over a strong fire, where they are continually stirred till their color is altered. Those of tin acquire by this process shades of gold color, with a metallic luster; copper, shades of flame color; those of iron or steel become blue or violet; those of tin or bismuth appear of a bluish-white color. The dust is then put through a flatting-mill, having polished steel rollers.

Me-tal'lic Pack'ing. Piston-packing consisting of a ring or several rings of iron or other metal, sometimes cast so as to possess elasticity in themselves, or sometimes cut into segments and pressed against the interior of the cylinder by springs, so as to form a steam-tight contact. See PISTON-PACKING.

Me-tal'lic Pa'per. Paper for memorandum-books, adapted to take an indelible mark from a leaden or pewter pencil. The paper is surfaced with a solution of lime, whiting, and size.

Me-tal'lic-tis'sue Loom. A loom for weaving with metallic threads, as in making gold and silver lace, braid, etc., entirely of metal, without any mixture of silk or other threads.

The wire is wound on hollow metallic bobbins, which are heated by the introduction of red-hot pieces of metal, and then allowed to cool, thus annealing the wire. The warp-threads (or wires) are then placed in the loom in the usual way. The weft must be somewhat finer than the warp, and a shuttle somewhat heavier than in silk weaving is used.

These looms are also used in making tissues in which the warp is of silk or thread and the weft of gold or silver wire or silk thread covered with a flattened silver wire which has been gilt.

Me-tal'lo-chrome. A coloring of metals by means of galvanism. It is an invention of Nobili, and consists in depositing thin films of a metal on metallic bodies by means of a galvanic battery, so as to form a number of rings. As the deposited rings — called, after the inventor, Nobili's rings — are not everywhere of the same thickness, they produce elevations and depressions, which, though not visible

...according to the shape of the metal into which the current enters, — be it a point, a slip, a cross, a concave or a convex disk, — so is the form of the colored figure varied. If, in addition to this, a pattern in card or gutta-percha is cut out and interposed between the two surfaces, the action is intercepted by the portions not removed, and the design is produced on the steel plate in colors that may be greatly varied, according to the duration of the experiment. The different colors are due to the different thicknesses of the films of peroxide of lead." — C. V. WALKER.

Met'al-log'ra-phy. 1. A process invented by Abate, in 1851. It consists in printing from wooden blocks upon metallic surfaces, so as to produce imitations of the grain of the wood. A veneer of wood is wetted with a solution of hydrochloric or sulphuric acid, and is then impressed upon the metal so as to cause the deposition of a colored metallic oxide.

Or the impression is taken on muslin, which is then in a condition to transfer it to the metal under pressure.

2. A substitute for lithography in which metallic plates are substituted for the lithographic stone. Kocher and Houssiaux of Paris use a surface of tin-foil backed by an alloy of lead and antimony, and strained around a roller which thus becomes the pressure and printing roller. The Exhibition of 1862 in Paris showed several varieties of this art, which, in one of its branches, is closely allied to the calico-printing by copper rollers of raised design.

Met'al-lur'gy. The art of separating metals from their ores or from impurities: *smelting, reducing, refining, alloying, parting, plating,* etc. See under the following heads: —

leg portions of figures. The belts are of different lengths, so as to mismatch the sections as they are revolved.

Me'te-or'o-log'i-cal In'stru-ments. See under METER for list; including BAROMETER, THERMOMETER, HYGROMETER, RAIN-METER, etc.

Me'te-or-om'e-ter. (*Telegraphy.*) An apparatus for receiving, at a local station, transmitting to a central station, by telegraph-wires, and there recording, the direction and velocity of the wind, condition of the barometer and thermometer, amount of rainfall, etc.

Stephen Chester of Elizabeth, New Jersey, patented in 1862 a telegraphic meteorometer which records at frequent intervals by a single wire, from as many instruments as may be desired, and at any distance; the purpose being to collect reports for the signal service. A clock-work mechanism at the sending station throws the wire alternately into connection with a registering anemometer, vane, barometer, thermometer, etc., at such intervals of time as may be decided upon.

The anemometer is of the windmill kind, and its shaft carries a tooth which breaks an electric circuit at each revolution. The rapidity of electric pulsations, therefore, indicates the velocity of the wind. The motion of the vane opens and closes various circuits as it traverses the circle, and so records itself.

Thermometric and barometric registration is obtained by making the mercury column a part of an electric circuit. As the columns rise and fall they make connection with a greater or less number of wires, which transmit their report to the line-wire as their turn comes. Other connections are obvious. The operations are to be conducted from the receiving station, where are also the recording instruments which register the indications of the various sending instruments, as they are consecutively and automatically connected by switch with the telegraphic wire.

Me'te-or'o-scope. An instrument used for taking angles, and making measurements of the heavenly bodies.

Me'te-or-steel. An alloyed steel which has a wavy appearance, resembling the Damascus steel.

An alloy of zinc, 80; nickel, 16; silver, 4 = 100, is placed in a black-lead crucible, covered with charcoal, and melted. It is rendered friable by pouring it into cold water, is reduced to powder, called *meteor-powder*, and is added to steel in a crucible in the following proportions: —

Digitized by Google

Blister steel, 28 pounds; meteor-powder, 10 ounces; chromate of iron, 8 ounces; charcoal, 1 ounce; quicklime, 2 ounces; porcelain-clay, 3 ounces.

These materials are melted in the usual manner, cast into an ingot, drawn into bars, and treated as cast-steel.

The wavy appearance may be farther brought out by washing the surface with dilute nitric acid; acid 1 part, water 19 parts.

Me'ter. (Fr. *Mètre.*) 1. The French unit of measurement of length, equal to 39.3708 inches, or 3.2809 feet. The $\frac{1}{10000000}$ part of the quadrant of the earth measured on a meridian. See METRIC SYSTEM.

One of the original set of iron meters, made in France, is now at the Coast Survey Museum in Washington, where are also the brass standard yard of England and many other standard measures and weights, home and foreign.

The new international meter-measure was cast, in the presence of the commission at Paris, in the laboratory of M. Sainte-Claire Deville. It consists of an alloy of platinum and iridium. Nine kilogrammes of platinum and one kilogramme of iridium were melted by means of the oxyhydrogen gas blowpipe. This process took three quarters of an hour; the molten mass was then let off into a mold made, like the crucible, from a block of limestone, whose inner surface was burnt to lime in consequence of the heat. The metal did not lose its luster in cooling, and was afterward shaped, tested, and graduated.

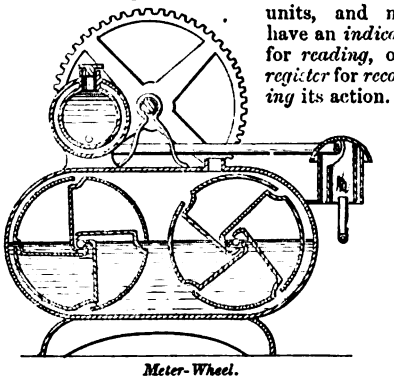
The terms *meter*, *register*, *counter*, *indicator*, are somewhat irregularly used, but are not exact synonyms. An *indicator* makes audible or visible notice of results or condition. A *register* records. A *meter* measures distance, capacity, power, etc., giving results usually in volumes or other units, and may have an *indicator* for *reading*, or a *register* for *recording* its action.

Fig. 3130.



Meter-Wheel.

Me'ter-wheel. One used in connection with gas and liquid meters and air-carbureting machines.

Digitized by Google

In the former, it is driven by the flow of gas whose volume it measures; and in the latter case it is usually employed to induce a flow of air through the hydrocarbon liquid, and performs the function of a blower. It has usually several chambers, and when measuring gas, is submerged above its axis in water, in the chamber wherein it rotates. The chambers in the wheel are of known capacity, and the revolutions are registered upon dials. In the gas-meter, the gas passes in at the hollow trunnion, and passes from the central pipe to each chamber in turn. As the gas fills the chamber it rises, and, when filled, its lip rises above the surface of the water and discharges its gas into the upper part of the containing-case. As the chambers of the drum pass over, they again fill with water. See GAS-METER.

Mete-stick. (*Nautical.*) A measure used in storing cargo, in order to preserve proper levels.

Met'o-pe. (*Architecture.*) The space between the triglyphs in the frieze of the Doric order.

Me-tren'chy-tes. (*Surgical.*) A syringe for injecting medicated liquids into the uterus.

Met'ric Sys'tem. The system adopted by the French convention in 1795, in which all measures of length, area, capacity, and weight are based upon the length of a quadrant of the meridian measured between the equator and the pole.

The origin of the system is due to the government of Louis XV., who named a commission to investigate the best means of reforming the great diversity of weights and measures then used in the different cities and provinces of France. These investigations were continued under his successor, and in 1790 Talleyrand distributed among the members of the National Assembly a proposal for the establishment of a single and universal standard of measurement.

A committee from the Academy of Sciences, Borda, Lagrange, Laplace, and Condorcet, all men of the highest scientific eminence, were appointed under a decree of the Assembly to report upon the selection of a natural standard. They proposed, in their report, that one ten-millionth part of a quarter circumference of the globe at the meridian of Paris should be taken as the unit of lineal measure.

This is undoubtedly a more definite standard than that of the English and American systems, which are based upon the length of a pendulum beating seconds in the latitudes of London and New York respectively. It may be remarked that the English and American determinations of the foot and yard from these sources differ slightly, though not enough to affect any practical result. The values of the meter are, in English inches, 39.37079; in American inches, 39.368. The values of the metric measures in the following tables are compared with those of the English yard.

Van Swinden was one of the commissioners for settling the basis of the system, and gives a lengthy description, from which we derive the following: —

"The standard is founded upon the basis of the quadrant of the earth, being the part of the terrestrial meridian contained between the equator and the north pole. The 10,000,000th part of this quadrantal arc was adopted to be the linear measuring unit, which they called "mètre," applying it equally to superficial and solid measures, taking for the unit of the former the square of the decuple, and for that of the latter the cube of the tenth part of the meter. They chose also for the measuring unit of weight, the quantity of distilled water equal in bulk to the same cube at a certain temperature. They also decided that the multiples and sub-multiples of each kind of measure, whether of weight, capacity, surface, or length, shall be always taken in the decimal or decuple proportion, as the most simple, natural, and easy for calculation, according to the system of numeration which all Europe has used for many centuries.

"The Institute (National Institute of France) ordered a new and actual measure of the whole arc of the meridian extending the whole length of France, from Dunkirk on the north to Barcelona in Spain, and passing Paris, an extent of almost 10°. The measurement of this arc employed Mechain and Delambre for several years. They employed rods of platinum of 12 feet in length for measuring the bases; and whole circles, accurately made, for taking the angles to 10ths of seconds, by repeating the measures in different parts of the circumference, and taking the mediums of the whole. The precision with which the angles were observed is such that, out of 90 triangles which connect the extremities of the meridional arc, there are 36 in which the sum of the 3 angles differs from its proper quantity by less than 1 second; that is, in which the error of the three angles taken together is less than 1 second; there are 27 triangles in which this error is less than 2 seconds; in 18 others it does not amount to 3 seconds; 4 are under 4 seconds; and the remaining 3 are under 5 seconds.

"Every care was taken to support and dispose the platinum rods properly in measuring the bases. The extremities of the rods were never brought into contact; an interval being left, which was measured by a tongue of platinum, sliding from the end of one of the rules and carrying a vernier and microscope. The corrections or allowances for differences of temperature, for obliquities of the line actually measured, and for the elevation above the level of the sea, were also attended to and allowed for. One rod was kept unemployed for a module or standard at 10° Reaumur or 54° Fah."

In deducing the length of the quadrant of the meridian, the arc measured by Bouguer and La Condamine in Peru, in 1736, was taken as an element. More recent and extended measurements at different points of the earth's surface indicate that the data upon which the metric determinations were founded were inadequate for ascertaining the exact variations in curvature of this irregular ellipsoid at different latitudes, and that consequently the meter is not exactly what it should be, but 10,000,000 meters fall short, according to Sir J. F. W. Herschel, by 4,008 feet of measuring a meridional quadrant. This error, amounting to but $\frac{1}{208}$ of an inch to the meter, is disregarded.

As before observed, the meter is the basis of all measurements. From it are derived the following units: —

Of area; the *are*, — 1 square decameter.

Of capacity; the *liter*, — 1 cubic decimeter.

Of weight; the *gram*, — 1 cubic decimeter of water.

The names of the graduations below the unit are formed from the Latin, and above the unit are formed from the Greek, as follows, the unit being 1: —

Myria	10,000
Kilo	1,000
Hecto	100
Deka	10
	1
Deci	0.1
Centi	0.01
Milli	0.001

In each of the four classes, — length, area, capacity, and weight, — these prefixes indicate the character of the measure. Greek for multiples, Latin for fractions.

Measures of Length.

Millimètre (.001 mètre),	0.03937	inches.
Centimètre (.01 mètre),	0.39371	"
Décimètre (.1 mètre),	3.93708	"
Mètre (unit),	39.3708	" or 3.2809 feet.
Dékamètre (10 mètres),	32.809	feet, or 10.9363 yards.
Hectomètre (100 mètres),	328.09	" 109.3633 "
Kilomètre (1,000 mètres),	1,093.63	yards, or 0.62138 miles.
Myriamètre (10,000 mètres),	10,936.33	" 6.21382 "

Table.

10 millimeters make	1 centimeter.
10 centimeters make	1 decimeter.
10 decimeters make	1 meter.
10 meters make	1 decameter.
10 decameters make	1 hectometer.
10 hectometers make	1 kilometer.
10 kilometers make	1 myriameter.

Measures of Area.

The unit of area is a square whose side is 10 meters. It is called an ARE, and is equal to 100 square meters.

Centiare (.01 are or square mètre),	1 1960 sq. yards=1,550 square inches.
Are (sq. décamètre and unit),	119.6033 sq. yards or 0.0247 acres=3.9536 p.
Decare (10 ares),	1,196.033 sq. yards or 0.247 acres=39.536 p.
Hectare (100 ares)	11,960.33 sq. yards or 2.471 acres=2 a. 1 r. 35.376 p.

Table.

100 centiares make	1 are.
10 ares make	1 decare.
10 decares make	1 hectare.

Measures of Capacity.

The unit for the measure of volumes is a cube whose edge is $\frac{1}{10}$ of the meter; that is, a cube whose edge is 3.937 inches. It is called a LITER, and is $\frac{1}{1000}$ part of a cubic meter.

Metric Denominations.			English Equivalents.		United States Liquid Measure.
Milliliter	0.001 of a liter	1 cubic centimeter	0.00704 gills	0.061027 cubic inches	0.27 fluid drams.
Centiliter	0.01 of a liter	10 cubic centimeters	0.0704 gills	0.610271 cubic inches	0.338 fluid oz.
Deciliter	0.1 of a liter	.1 cubic decimeter	0.704 gills	6.102705 cubic inches	0.845 gill.
Liter	1 liter	1 cubic decimeter	1.761 pts.	61.027052 cubic inches	1.0567 quart.
Decaliter	10 liters	10 cubic decimeters	2.201 galls.	610.270515 cubic inches	2.6417 galls.
Hectoliter	100 liters	.1 cubic meter	2.751 bus.	6,102.705152 cubic inches	26.417 galls.
Kiloliter or stere	1,000 liters	1 cubic meter	27.512 bus.	61,027.051519 cubic inches	264 17 galls.

Table.

10 milliliters make	1 centiliter.
10 centiliters make	1 deciliter.
10 deciliters make	1 liter.
10 liters make	1 decaliter.
10 decaliters make	1 hectoliter.
10 hectoliters make	1 kiloliter or stere.

Weights.

The unit of weight is equal to $\frac{1}{1000000}$ part of the weight of a cubic meter of pure rain-water weighed in a vacuum. It is called a GRAM, and is equal to 15.432 grains Troy = .0352746 ounces avoirdupois, nearly.

METRIC DENOMINATIONS AND VALUES.			Equivalents in denominations in use.
Names.	Number of Grams.	Weight of what quantity of water at maximum density.	Avoir'pois.
Milligram	0.001	1 cubic millimeter	0.0154 gr.
Centigram	0.01	10 cub. millimeters	0.1543 gr.
Decigram	0.1	.1 cub. centimeter	1.5432 gr.
Gram	1	1 cub. centimeter	15.432 gr.
Dekagram	10	10 cub. centimeters	0.3527 oz.
Hectogram	100	1 deciliter	3.5274 oz.
Kilogram or kilo	1,000	1 liter	2.2046 lbs.
Myriagram	10,000	10 liters	22.046 lbs.
Quintal	100,000	1 hectoliter	220.46 lbs.
Millier or ton	1,000,000	1 cubic meter	2,204.6 lbs.

Table.

10 milligrams make	1 centigram.
10 centigrams make	1 decigram.
10 decigrams make	1 gram.
10 GRAMS make	1 decagram.
10 decagrams make	1 kilogram.
10 kilograms make	1 myriagram
10 myriagrams make	1 quintal.
10 quintals make	1 millier or ton.

On the adoption of the metric system, the French also reformed their currency, abolishing the *livre* and *sous*, and adopting the *franc*, which it was decreed should weigh five grams, and be composed of 9 parts pure silver and 1 part alloy. It is divided into 100 centimes. This piece constitutes the basis of the French coinage.

The United States, however, led the way in a decimal currency.

The metric system, though adopted in 1795, was not fully carried into effect until 1840. It is now employed throughout a large part of Continental Europe, and seems in a fair way to be generally adopted at some not very distant day in the United States, where it may now be legally employed at the option of the parties interested.

Met'ro-chrome. A color-measurer. Invented by Field and described in his "Chromatograph." It consists of three hollow wedges of glass, of exactly the same angle and capacity, and accurately graduated on the edge to the same number of equal degrees. These wedges are so arranged between two screens that any portion of their tapering sides may be presented at will to an aperture through which a direct view may be had, or a ray of light thrown. The wedges are filled respectively with a yellow, a red, and a blue transparent liquid, each color being exactly the same in depth or intensity. It is obvious that, descending from the apex to the base of these wedges, the amount of color or the number of its atoms presented to the eye increases in proportion to the divergence of its sides.

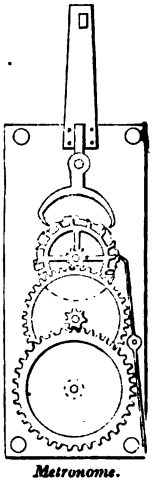
Met'ro-graph. An apparatus to be attached to a locomotive, indicating on a time-paper the speed with the number and duration of the various stoppages.

Me-trom'e-ter. (*Surgical.*) An instrument for measuring the size of the womb. A *hysteromcter*.

Met'ro-nome. An instrument for beating and dividing the time in music. A musical time-keeper. Patented in England by John Mälzel, December 5, 1815.

It has a small pendulum which, being set in motion by clock-work, beats audibly a certain number of

Fig. 3131.



Metronome.

Digitized by Google

times in a minute ; and this number may be altered by moving a sliding weight so as to give it the speed required.

In Fig. 3131, the verge-wheel is attached to a wheel having equal raised surfaces and depressions around its periphery, and these act on one end of a pivoted lever, whose other end is connected by a fine thread to an indicator attached to a spiral spring.

Met'ro-scope. (*Surgical.*) An instrument invented by M. Nauche, for listening to the sounds of the heart of the fetus in utero gestation. The extremity was suggested by the stethoscope of Laënnec, and is introduced through the vagina and applied against the neck of the uterus. It is used when the sounds and movements are imperceptible through the parieties of the abdomen.

Met'ro-tome. (*Surgical.*) An instrument like a bistoury caché, which is introduced into the cavity of the uterus, where the knife is unsheathed and cuts on withdrawing. Its purpose is to divide the neck of the uterus. See Thomas's "Diseases of Women." A *hysterotome.*

Mez-za-nine'. A low window occurring in attics and entresols.

Sometimes applied to an *entresol.*

A *mezzanine story* is a half-story ; one lower than the stories above and below it.

Mez'zo-ri-li-e'vo. The moderate prominence of a sculptured figure from the plane surface to which it is attached. It is also known as *demi* or *half-relief,* and is a grade between *alto-rilievo* or *high-relief,* and *basso-rilievo* or *low-relief.* See Rilievo.

Mez'zo-tint-en-grav'ing. The inventor of this art is believed to have been Colonel Ludwig von Siegen, a lieutenant-colonel in the service of the Landgrave of Hesse Cassel. Portraits executed by him exist, having the date of 1643. Prince Rupert gave so much attention to it, and was so instrumental in bringing it into favor, that he has been credited with the invention. Sir Christopher Wren has also been cited as the inventor, but his claims are antedated by Prince Rupert.

"Mr. Evelyn showed me the whole secret of mezzo-tinto, and the manner of it, which is very pretty, and good things done with it." — Pepys's *Diary,* November 1, 1665.

The process consists in passing over a plate of steel or copper with an instrument called a *cradle,* by which a burr is raised over every portion of the plate, which, if filled with ink by the printer, would make a black impression. On the surface thus prepared, the lights and middle tints are burnished or scraped away ; the burr being more or less perfectly removed, according to the gradation of light required. The plate is untouched in the parts intended for the darkest tint. The instruments used are the cradle or rocker, scraper, burnisher, roulettes. It is usual to etch-in the outlines of the design to form a guide in the operations of scraping and burnishing. A more extensive use of the etching process gives character and force to the work. The tools, cited above, are described under their respective heads.

Mi'ca. A mineral which cleaves into thin transparent plates. Known to miners as *glimmer.* It is the *lapis specularis* of Pliny, used in ancient times for window-panes.

The uses of mica in the mechanic arts are numerous. Among them may be cited, —

Windows for stoves and lanterns.

Chimneys for lamps.

Ground, as a lubricator and as a packing.

As a substitute for glass in spectacles, in protecting the eyes in various mechanical operations.

As a substitute for glass in silvered reflectors, in places where it will be exposed to heat, as in headlights, etc. (Marshall's patent.)

Mixed with varnish as a coating for wall-paper (Beck's patent), and in bronzing statuettes and other plastic articles.

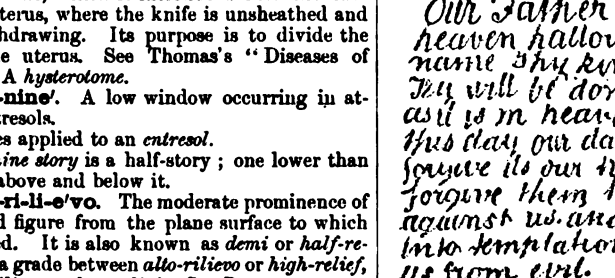
As a covering for roofs (Ditto's patent).

Mi'cro-cous'tic. (*Surgical.*) An aural instrument for collecting sounds for the partially deaf. An auricle or speaking-trumpet.

Mi'cro-graph. An instrument invented by Mr. Webb of London, for executing extremely minute writing and engraving ; its general principle is that of the pantograph.

Fig. 3132 is a *fac-simile* of a photograph enlarged, from a specimen written by Mr. Webb on glass for

Fig. 3132.



Our Father which art in
heaven hallowed be Thy
name Thy kingdom come
Thy will be done in earth
as it is in heaven Give us
this day our daily bread and
forgive us our trespasses as we
forgive them that trespass
against us and lead us not
into temptation, but deliver
us from evil. Amen.

The Lord's Prayer (from a Micro-photograph of the original Writing on Glass, occupying the $\frac{1}{129654}$ of a Square Inch).

the United States Army Medical Museum. The glass slip also contains the following inscription in a larger writing : —

"Webb's Test. The Lord's Prayer. 227 letters in the $\frac{1}{274} \times \frac{1}{274}$ of an inch, or the $\frac{1}{129654}$ of a square inch, and at the rate of 29,431,458 letters to an inch, which is more than 8 Bibles, the Bible containing 3,566,480 letters."

The area within which the Prayer was written was micrometrically verified by Dr. J. J. Woodward, United States Army, who found that it and the above inscription were contained within a space $\frac{1}{75}$ of an inch square.

Mr. Webb claims that writing of this kind affords a test of microscopic power superior to that afforded by Nobert's Plates (which see), the finest of which he endeavors to prove have no real existence, but result from an optical delusion produced by the polarization of light. Dr. Woodward, however, says that the optical appearance of such of Nobert's bands as have never been resolved into separate lines by the highest powers yet attained are so similar to the others that it is unreasonable to doubt that they are ruled as stated by Nobert. He attributes the success of Nobert to the minuteness of the points employed by him, which appear to far exceed those of other artists, and are the result of a secret which he has hitherto kept to himself.

According to a statement made in 1862 by Mr. Farrants, president of the Microscopical Society, Mr. Peters has succeeded in writing the Lord's Prayer, so as to be distinctly legible, with sufficient magnifying power, within the space of $\frac{1}{256000}$ of a square inch. The instrument employed was invented by him, and is termed the Micropantograph (which see).

Mi-crom'e-ter. An instrument used with a telescope or microscope to measure small distances, or the apparent diameters of objects which subtend very small angles. — Webster.

Digitized by Google

Micrometers are variously constructed. The field of the telescope may be provided with a graduated scale, or a metallic ring, or a diaphragm having parallel and intersecting spider-lines or fine wires.

The micrometer with a *graduated scale* is used for measuring distances by direct comparison.

The application of the micrometer to the telescope is credited by Whewell to Huyghens, Malvasia, and Azout. It was a great advance in the attempt to do by accuracy of measurement what had previously been attempted, and in part accomplished, by enlarging the instrument so as to enable the measurements of smaller arcs.

The first micrometer on record is that of Gascoigne of England, constructed about 1640, and used by him in measuring the diameters of the moon and some of the planets.

The inventor perished in the civil war, 1644. The instrument had nicely ground parallel edges of brass plate, and parallel hairs were substituted by the renowned Dr. Hooke.

Huyghens, about 1652, measured the diameter of a planet by inserting in the tube of the telescope, at the focus of the object-glass and eye-glass, a slip of metal which covered exactly the image of the planet, and then deduced the diameter by the breadth of the slip compared with the breadth of the field.

Malvasia, shortly after, employed a network of fine silver wire, making a *reticulated* or *filar micrometer*. The wires were stretched across a diaphragm in his telescope, crossing each other at right angles and dividing the field of view into squares of equal size.

Azout, a French astronomer, published an account of the micrometer in 1667.

Picard, another French savant, who died in 1684, was instrumental in the practical application of the micrometer to instruments. He early adapted the telescope to the measurement of angles, and determined with reasonable correctness the length of a degree, which he measured by means of an ODOMETER (which see).

Roemer, in 1678, suggested the *divided object-glass micrometer*, which was more perfectly adapted by Bouguer, seventy years afterwards.

Boscovich, in 1740, invented the *circular micrometer*, which was used by Lecaille in 1742, and Olbers, 1798, and improved by Frauenhofer.

Ramsden, about 1780, suggested the use of *cobwebs* as a fine filament substitute for wire. It has been credited to Troughton.

A substitute for the spider-line micrometer, over which it possesses many advantages, is formed of a thin plate of glass on which equidistant parallel lines are ruled by means of a diamond-point. Spider-lines are liable to become displaced or to become relaxed in consequence of the hygrometric conditions of the atmosphere, while the glass plate is permanent and unalterable.

Rochon invented the *double-refraction* or *prism micrometer*.

A filament of silk, a fiber of spun-glass, of melted sealing-wax, of asbestos, or a minute crystal of mezzolite, were successively suggested and employed. Wollaston adopted a platinum wire, drawn to extreme tenuity by inclosing it in a plug of silver, afterward removed by acid; this is illuminated by a ray of light which passes from a lamp along the horizontal axis, and is reflected by a small speculum upon the wire.

The wires of the Oxford heliometer (England) are illuminated by a voltaic current, which renders them red-hot.

Porro illuminates the wires by a thin vein of light perpendicular to the axis of the telescope, so as to make the wires silvery white in a dark field.

Brewster proposed to obtain micrometer lines by placing in the field of view the reflected images of a fixed or movable system of wires or of lucid disks attached to the side of the eye-piece.

The photographic micrometer is thus described by Sir David: —

"If a system of opaque or transparent lines be impressed upon the collodion photographically when reduced to the minutest size, from a system of large and sharply defined lines, we shall have the most perfect micrometrical scale that can be conceived; the portion of collodion that contains no nitrate of silver being as transparent as if the dark places were solid wires or metallic plates placed in the focus of the eye-glass."

See Pearson's "Practical Astronomy," Vol. II.; Brewster's "Philosophical Instruments."

Cavallo's micrometer is a small, semi-transparent scale of mother-of-pearl, about $\frac{1}{10}$ of an inch broad and divided by finely ruled lines. It is situated within the tube, at the focus of the eye-lens of the telescope, with its divided edge in convenient proximity to the image.

Megameter.	

Mi-crom'e-ter-bal'ance. Kenshaw's micrometer-balance, invented about 1842, consists of a beam or steelyard supported on a knife-edged fulcrum. Near one end of the beam a few threads are cut, on which is a wheel graduated to degrees, each of which corresponds to half a grain in weight. The coin is placed on the other end of the beam, and if of correct weight an index-bar points to zero on the wheel; but if it be light, the wheel is turned round, altering the leverage of the beam until it is in equilibrio. The degree to which the index-bar points shows how many half-grains the coin is short of its proper weight. The device may be adjusted to weigh half-sovereigns.

Mi-crom'e-ter-mi'cro-scope. The *micrometer-microscope* is used for reading and subdividing the divisions of large astronomical and geodetical instruments. (WEBSTER.) Around the mural circle of the Washington Observatory are placed six micrometer-microscopes, with an acute cross of wires at their foci for reading angles less than 5′. Five revolutions of the micrometer are designed to measure 5′ upon the circle. The micrometer heads being divided into sixty equal parts, each division represents 1″ of arc.

Mi-crom'e-ter-screw. A screw attached to optical and mathematical instruments as a means for exact measurement of very small angles.

The great space through which the lever of the screw passes, in comparison with the longitudinal motion due to the pitch, affords the means for a positive motion which is imperceptible on the object moved, though appreciable in its results.

The head of the micrometer-screw being divided into sixty equal parts, and representing 1′ of arc, a revolution would be equal to 1°.

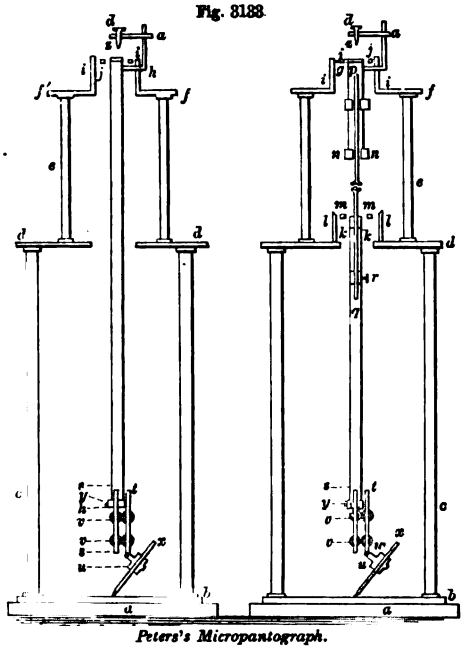
Digitized by Google

If the thread of a micrometer-screw in an instrument has 50 threads to an inch, and carries a pointer which traverses a graduated circle divided into 20 equal parts, the revolution of the micrometer-screw for a distance equal to one of the divisions will move the object to which the screw is attached $\frac{1}{1000}$ of an inch; that is, $20 \times 50 = 1{,}000$. See MEASURING-INSTRUMENT.

Mi'cro-nom'e-ter. A species of watch intended for measuring short intervals of time, as the flight of a projectile, etc., has been thus called. After being wound up in the ordinary way it is set in motion by pressing a spring with the finger, upon withdrawing which it is instantaneously stopped.

Mi'cro-pan'to-graph. An instrument invented in 1852 by Mr. Peters, an English banker and microscopist, for minute writing. It consists of an upright stand having four columns *c c* supporting a

Fig. 3133.



Peters's Micropantograph.

brass plate *d d*, on which are placed four smaller columns *e e*. On top of these is a second plate *f f* and ring *i i*, in which is journaled an interior ring *j j*; in this is pivoted a lever *g* having its arms in the proportion of 125 to 1. To the shorter arm of the lever is attached an arm *h* carrying the writing-point and sliding-arm *d a*. The lower end of the tubular lever *q* is caused to move in any required direction by means of the rods *s t*, which are connected by two pair of rings *v*, each pair joined together in one plane and each moving on horizontal pivots. The first enters the lower end of the lever *q*, and the second may be moved vertically, and has at its lower end a joint *u* connecting it with the arm *w* which carries the tracing-point; this being moved over the outlines of the letters of a piece of writing or other object, the tracer *d* at the top of the machine produces a reduced copy on a plate of glass fixed beneath it. In the example, this would be reduced to $\frac{1}{12}$ the linear dimensions of the original, or $\frac{1}{1\,5\,6\,2\,5}$ of its area. This apparatus was improved by the inventor (see right-hand figure), who added an intermediate lever *p* consisting of two parts united by a universal joint; its ends slide in bearings *n n*, *k k* at the ends of the separated parts of the lever *g*, so that the relative lengths of the two parts, which in fact constitute the arms of a compound lever, may be varied within certain limits, so as to vary the proportion between the original and the reduction. The amount of diminution which the instrument is capable of producing may, by thus adjusting the relative length of the levers, be raised between 108 and 6,250 times, lineal measurement.

The writing or engraving point *d* is pressed against the glass plate on which the reduction is made or raised therefrom by springs, a connecting-rod, and a lever operated by the left hand, while the right is occupied with the tracer *x*. See MICROGRAPH; Fig. 3132.

It was stated in 1862 by Mr. Farrants, that the Lord's Prayer, containing 223 letters (*amen* being omitted), had been written on glass with this instrument within the space of $\frac{1}{1\,5\,6\,0\,0\,0}$ of a square inch; at which rate the whole Bible might be inscribed within the $\frac{1}{4\,0}$ part of a square inch.

Mi'cro-phone. An instrument for increasing the intensity of low sounds by communicating their vibrations to a more sonorous body which emits a more audible sound.

Mi'cro-scope. An optical instrument by which objects too small to be viewed by the naked eye may be seen and examined.

A *single* or simple microscope is one by which the object is seen directly; it may consist of a single lens or of more than one.

In a *compound* microscope two or more lenses are so arranged that the image formed by one is magnified by the others, and viewed as if it were the object itself.

In a *solar* microscope a reflector and condenser are employed to direct the sun's rays on the object.

In a *lucernal* microscope the rays of a lamp are similarly directed.

The magnifying power of glass balls was known in early times to the Chinese, Japanese, Assyrians, and Egyptians, and more lately among the Greeks and Romans. The use of lenses for microscopes long preceded their application to telescopes. Sir David Brewster exhibited one in 1852 which was made of rock crystal, and was found among the ruins of Nineveh.

The refractive power of glass was known to Ptolemy, who gives a table of the deviation luminous rays experience when passing through glass under different angles of incidence. Descartes discovered the law that the amount of this refraction is proportional to the sine of the angle of incidence, and from that time date all great discoveries in optics.

Glass balls, called burning spheres, were sold in Athens before the Christian era. Their magnifying power was mentioned by the Roman philosopher Seneca, and by Porta of Naples in his "Magia Naturalis," published in 1590.

Alhazen, A. D. 1100, was the first to correct the popular error as to the nature of vision, showing that the rays came from the object and did not issue from the eye, as had been previously supposed. He determined that the retina is the seat of vision, and that impressions made on it by light are conveyed from it along the optic nerve to the brain; he explained that the formation of the visual images on corresponding portions of the two retinas is the cause of our seeing single when we use both eyes; he showed that a ray of light entering the atmosphere obliquely is deflected and follows a curvilinear path, owing to the increasing density of the air as the rays travel towards the earth, and deduced

Digitized by Google

from the data that the limit of the hight of the atmosphere is about 58½ miles.

Huyghens states that Drebell had a microscope in 1621, and that he was the reputed inventor of it; the invention is also claimed by Fontana, a Neapolitan, in 1618. Burrell asserts that the Jansens, father and son, made the first microscope and presented it to Prince Maurice and Archduke Albert of Austria. The invention was, however, clearly anticipated by Roger Bacon. Spectacles were in use A. D. 1200. The double microscope was invented by Farncelli in 1624.

Dr. Hooke (1635–1702) made microscopes of a sphere of glass, from $\frac{1}{20}$ to $\frac{1}{50}$ of an inch in diameter. Having made and polished his lens, he placed it against a small hole in a thin piece of metal and fixed it with wax.

Leuwenhoeck's microscopes, 26 in number, which he presented to the Royal Society, have each a double-convex lens. Their powers were from 40 to 160.

"Comes Mr. Reeve, with a microscope and a scotoscope. For the first I did give him £5 10 *s.*, a great price, but a most curious bawble it is." — PEPYS's *Diary*, 1664.

Stephen Gray's "poor-man's microscope," 1696, was merely a drop of water suspended at the end of a wire or pin. A piece of perforated cardboard or sheet-metal affords a better means of holding the drop of water, whose rounded surfaces give it the properties of a lens.

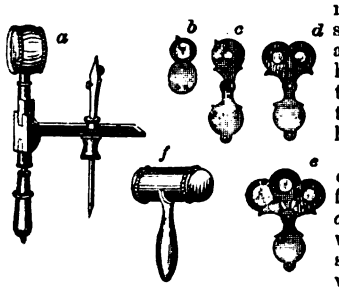
By fusing in the flame of a spirit-lamp a small piece of glass contained within a ring of platinum-wire, a lens may be formed. A piece of the wire should project, so as to form a handle.

Plate-glass is the material commonly used for microscopic lenses. Flint-glass, on account of its great dispersive power, is unsuited for the purpose. Rock-crystal is an excellent material. The diamond and other precious stones have been employed, but the advantage of their high refractive power is found to be counterbalanced by their color, reflective power, double refraction, and heterogeneous structure. The crystalline lenses from the eyes of small fishes give a very perfect image of minute objects.

The lineal magnifying power of a single lens is equal to the distance of distinct vision divided by the focal length of the lens. The object is brought a little within the focal distance of the lens and appears erect.

Fig. 3134, *a* is a jointed microscope for flowers, insects, etc., and is made to fold up and be carried in the pocket. The holder is movable in the slide for focal adjustment and has forceps between which the object is held.

Fig. 3134.



Microscopes.

Simple microscopes, to fold in cases, *b c d e*, are made with one or several lenses, which have a diameter of from ⅔ inch to 1½ inches. They are variously mounted.

The Stanhope lens *f* was invented by Earl Stanhope, and is a cylinder of glass with two convex ends. It is 1½ inches in length and ½ inch in diameter, and is mounted in a metallic tube. The ends have a relative convexity of 6 to 1, and the instrument has considerable power.

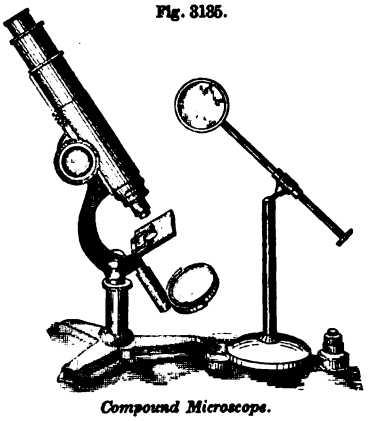
The "Craig" microscope comprises a single lens mounted on a stand, a glass for holding objects below it, and a mirror for reflecting light on the under side of the object and lens. The magnifying power is greater than that of the cheapest compound microscopes, and the instrument simple and convenient to use.

The compound microscope usually has three lenses, — the object-glass, the field-glass, which intercepts the extreme rays passing through the object-glass and thus enlarges the field of view, and the eye-glass. It shows objects in an inverted position. See also OBJECTIVE.

The United States army microscope, made by Zentmayer, is thus described: It has a brass body, 16 inches high, on brass stand, with joint to incline it to any angle, double-milled head-rack and pinion for coarse adjustment, micrometer-screw for fine adjustment, and movable glass stage; under the stage a tube is fitted for carrying the accessory illuminating apparatus, concave and plane mirrors, arranged for direct or oblique illumination, two eye-pieces, one achromatic object-glass $\frac{8}{10}$ of an inch focus, of 24 degrees angular aperture, one achromatic object-glass ¼ of an inch focus, of 80 degrees angular aperture (not adjustable for glass cover), giving power of 50, 100, 250, and 450 diameters: camera lucida, stage micrometer ruled $\frac{1}{100}$ and $\frac{1}{1000}$ of an inch, and a condensing lens two inches diameter on separate stand.

Fig. 3135 represents a microscope especially designed for dentists' use. It has a rack and pinion

Fig. 3135.



Compound Microscope.

for approximate, and a milled headed screw for accurate, adjustment of the focus, and is provided with two objectives having magnifying powers of 125 and 230 diameters respectively. It has also two mirrors, a plane and a concave, a revolvable and removable diaphragm, and a condensing lens on a separate stand.

Daylight or strong artificial light suffices for the observation of an object under a lens or microscope of moderate power, but with high powers more light is required, especially as the object is shaded by the lens. The condenser, a convex lens placed at the side of the object which is in its focus, is then employed. The light may be also concentrated on the object by a reflector.

Lieberkuhn, 1740, devised a hollow concave reflector with a hole in the center, in which was placed a

Digitized by Google

small lens, the foci of the lens and mirror nearly coinciding. This throws abundance of light on an object placed in the focus, but as it comes equally from all sides no shadows are formed and the object is difficult to define. The device is, however, well adapted for the detection of small particles of metal, etc., in ores.

The Abbé Huc exhibited his microscope to the Regent of Thibet at Lha-Ssa.

"An exceedingly robust specimen of the *pediculus* was kindly furnished by a noble Lama, the secretary to the Regent, from his own preserves. When seized by the nippers, the Lama objected that the experiment would cause the death of a living creature. 'Be silent,' said the Regent. '*Tsong-Kaba!*' cried he, when invited to apply his eye to the glass; 'the creature is as big as a rat.' After looking at it a few moments, he hid his face with his hands, saying it was too horrible to look at. Every one approached the microscope in his turn, and every one started from it with cries of horror. The Lama plead for his little parasite. We removed the pincers and let it fall into the hand of its proprietor. Alas! the poor victim was motionless. The Regent said to his secretary, laughing, 'I think your animal is indisposed. Give it some medicine.'" — *Abbé Huc's Travels in Tartary and Thibet*, 1844–46.

The solar microscope consists essentially of two lenses and a mirror. The mirror reflects the sun's rays upon the first lens, by which they are concentrated on an object placed in its focus, and is still farther magnified by a second lens, which throws the image on a screen at some distance behind it. The exterior lens is placed in a hole through the shutter of a darkened room, and the mirror is adjustable so that it may receive the sun's rays under a proper angle to be reflected to the lenses. The object is here supposed to be transparent; if it is opaque, it must be so illuminated that the rays reflected by it shall pass directly to the interior lens.

The theory of the solar microscope is said to have been invented by Dr. Hooke, and was described by Professor Balthasaurs in Erlange in 1710; but its practical execution is due to Dr. Lieberkuhn in Berlin, who made the first successful apparatus in 1740. It is founded on the same principle as the *camera obscura*, only in place of causing the lens or lenses to form inside of the apparatus a small image of large exterior objects, as is the case with the *camera obscura*, on the contrary, in the solar microscope, the lens or lenses form outside of the apparatus a large image of small objects placed inside the apparatus.

When the objects are opaque and illuminated in front by reflecting mirrors, the apparatus has been called a *megascope*.

The apparatus of the hydro-oxygen and the electric microscope is identical with that of the solar microscope, only that for the solar rays, which are not always at command, the so-called Drummond, lime, hydro-oxygen, or electric light is substituted. The magnesium light has also been used in this way. Either of the above is inferior to the solar microscope in the same ratio that our best artificial lights are inferior to the solar light.

A modification of the above has been adapted for producing enlarged photographs of small objects. The enlarged photograph on glass is then placed in the magic-lantern or stereopticon, and re-enlarged for the benefit of the audience. Or the enlarged view may be taken upon the prepared surface of a wooden block, ready for the skill of the engraver. A beautiful set of engravings, thus produced, were given in Harpers' Magazine some years back.

The mode of obtaining enlarged prints from negatives of ordinary size is explained under SOLAR CAMERA. We are much indebted to Mr. Shive of Philadelphia for the improvements in this apparatus.

The variety of objects which afford interesting subjects for examination by the microscope is infinite. For such, the reader is referred to works treating the subject specially. It is also useful for detecting adulterations in food, drugs, and fabrics, and in many branches of scientific and medical investigation its aid is indispensable. Another use to which it may be applied was disclosed during the late Franco-Prussian war. Copies of newspapers, reduced many-fold in size by photography, were fastened in large numbers to carrier-pigeons and introduced into besieged cities. These were easily read by the microscope.

Microscopic writing has of late years attracted some attention. It is done by means of an instrument composed of a series of connected levers. The operator writes or traces with the longest lever of the system, while the shortest, which carries a marking instrument, faithfully copies whatever may be written. It was calculated that with Peters's machine, at the London Exhibition of 1862, the whole Bible might be copied 22 times in the space of one square inch. It has been proposed to apply this invention to practical use by making private marks, visible only under the microscope, to bills and other papers of value, as a protection against fraudulent imitations; being so minute, a counterfeiter would fail to perceive them, while they would be easily recognized by the proper parties. See MICROGRAPH; MICROPANTOGRAPH.

The prices, as well as the construction, of microscopes vary greatly; those having a magnifying power of less than 200 may be made comparatively simple and at a relatively cheap rate, but when the magnifying power exceeds 300 the whole apparatus becomes more complex, and must be more carefully made in order to handle, focus, and illuminate the objects properly, center the lens correctly, etc. In these the stand alone costs nearly $100, the eye-glasses $5 to $10 each, and the object-glass on Selligne's system from $10 to $75 each, according to power.

Besides eye-pieces and objectives of different powers, there are a number of necessary or useful appendages, as, condensing lens, prismatic illuminator, dark well, parabolic reflector, lieberkuhn, polarizing prism, micrometer, camera for delineating objects, etc., which tend to augment the price, so that a complete compound microscope costs from $300 to $1,000. The binocular microscope is, of course, still more expensive, the price in some instances reaching $15,000. A good instrument, however, amply sufficing for the wants of ordinary amateur observers, may be obtained for $100.

See "Carpenter on the Microscope"; Hogg's "History of the Microscope," etc.

The investigations of Leuwenhoeck, Schwammerdam, and the earlier microscopic inquirers, were conducted by means of single lenses, the compound microscope being esteemed comparatively untrustworthy, its true theory being imperfectly understood.

In 1829, Mr. J. J. Lister published the results of his investigations into the laws governing the aberrations of lenses, and gave practical directions for correcting them by combinations of lenses so arranged that the aberrations should balance each; from this period date the great and rapid improvements which have since been made in the compound microscope.

Among recent important improvements in the microscope is the illuminator of Professor Hamilton L. Smith, for opaque objects, in which the light is

Digitized by Google

received upon a mirror behind the object-glass, through which it is reflected upon the object. Also his mechanical finger, by which objects invisible to the naked eye are picked up on the point of a hair, separated according to kind, and arranged conveniently for observation.

After the discovery of the theory of binocular vision by Wheatstone in 1838, and especially after the construction of the lenticular stereoscope by Sir David Brewster in 1852, the idea naturally occurred of applying this principle to microscopes. This was first effected by Professor J. L. Riddell of the University of Louisiana. He employed a pair of small rectangular prisms immediately behind the object-glass; these received the incident rays and reflected them through a second pair of similar prisms to the eye of the observer. This arrangement had the disadvantage of reversing the stereoscopic effect, projections appearing as depressions, and *vice versa*.

The first arrangement for producing a correct stereoscopic effect was invented by Mr. Nachet, and consisted of an equilateral prism which divided the pencil of rays into two equal parts, reflecting them to two similar prisms, right and left hand, which reflected them to the eye of the observer.

The Wenham binocular (Fig. 687, p. 285), in which the compound pencil is divided by means of a trapezoidal prism, has, however, on account of its greater simplicity of construction, been more generally employed.

Mr. Nachet has since introduced a simpler form of binocular microscope, which may be applied to an ordinary instrument without altering its construction or impairing its usefulness as a monocular. This is effected by making an opening in the side of the tube, into which is introduced a rectangular prism which reflects half the pencil of rays horizontally; this is received on another prism, which directs it to the eye of the observer. Arrangements are made for varying the distance between the tubes to accommodate them to the varying distances between the eyes of different persons.

The disadvantage common to binocular microscopes on this plan is that they perform well only with comparatively low magnifying powers. This led to the suggestion a few years ago by Mr. Wenham of a method of dividing the pencil by means of a transparent plane reflector, which, adjusted at a proper angle, might reflect one half the light of each pencil, allowing the other half to pass through. This plan involves the loss of the stereoscopic effect, but secures to the observer the satisfaction of using both eyes in viewing an object. It has, however, proved somewhat difficult to carry out this idea satisfactorily in practice. See PRISM.

Messrs. Powell and Lealand of London have patented an arrangement, consisting of a quadrangular prism which receives the rays, part of which pass through, while the remainder are reflected to a triangular prism which transmits them to the eye. This has the disadvantage of causing the object to appear unequally illuminated in the two tubes.

Mr. R. B. Tolles has constructed an instrument designed to remedy the defects of the original binocular microscope, at the same time permitting the ordinary single-tubed instrument to be used as a binocular. The double eye-piece has prisms similar to those employed in Nachet's earliest form, placed at a distance from the objective about equal to that of ordinary eye-pieces. In this form it is necessary that the axes of the pencils of rays should cross each other a second time, and for this purpose an erecting eye-piece is employed.

Professor H. L. Smith has proposed a form of binocular, consisting of a thin plane reflector, inclined at an angle of 80° to the axis of the telescope; a ray of light from the object, striking the surface of the mirror, is in part transmitted without change of direction, and in part reflected to a triangular prism having one of its angles truncated, where it undergoes a second reflection to correct the reversal produced by the first, and is transmitted along the axis of the secondary tube. By this arrangement, the intensities of the light of the directly viewed and reflected images appear sensibly equal.

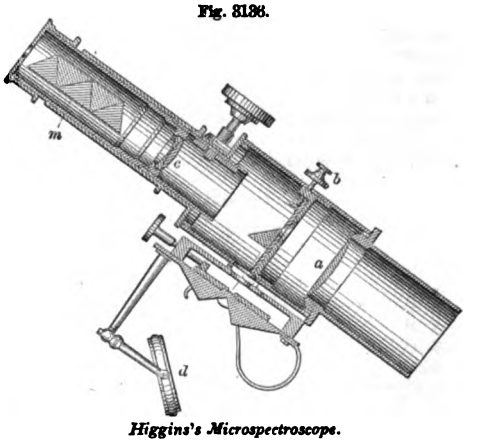
It is obvious that, after the division of the beam of light from the object, it is merely a matter of detail to give each of the divisions a direction proper to be viewed by two or more observers. This affords great advantages, not only in anatomical and other investigations, but, where the instrument is used merely for curiosity, it enables several persons to observe at the same time, thus greatly economizing time.

In the triple microscope for three observers, the beam of light is divided into three equal parts by a combination of suitable prisms, each part being directed into its proper tube. Provision is made for the general adjustment of the lenses, and also for the adjustment of the eye-piece of each tube to the eye of the particular observer.

The construction of the *stand* is a matter of considerable importance, as upon its arrangement largely depends the degree of illumination and the distinctness with which the objects can be viewed. A good arrangement of this kind, constructed by Tolles, comprises a movable stage having two tables, one facing upward and the other downward, firmly connected together and controlled by milled heads. When the object is placed on the lower table, it is secured by spring clips. In this case, the central part of the upper table is removed, and the objective descends through the opening. Any degree of obliquity of illumination, even up to 90°, is thus available for viewing the object. The stage is also capable of rotation on its optical center throughout the entire circle.

Mi'cro-spec'tro-scope. A spectroscope placed in connection with a microscope, in order that the

Fig. 3136.



Higgins's Microspectroscope.

absorption lines may be the more accurately measured. The eye-piece contains prisms so placed as to enable the reflected ray to pass in a direct line to the eye. *a* is the first lens of the eye-piece; *b* the screw for adjusting the slit which reduces the beam to a line of light; *c* is the second lens, where the rays

Digitized by Google

are rendered parallel, after which they pass through three crown-glass prisms *m*, placed in one direction, and two flint-glass prisms, placed in the other direction, so that the spectrum is seen by looking straight at the source of light, the instrument being a direct-vision spectroscope.

The instrument is notably employed in viewing the absorption bands of blood in toxicological research. By means of the mirror *d*, a ray of light, shown by the dotted line, may be sent through a slit at one side of the instrument, which, being reflected upward, passes through the prisms along with the other light which came from the object under the microscope, and by this means the two spectra may be compared, one object being a liquid supposed to be blood, and the other one known to be blood, and so on.

Mi'cro-tome. A knife for making thin sections for microscopic examination. A pair of parallel knives in a single haft. See PARALLEL KNIFE.

Mid'dle-cut File. A file whose teeth have a grade of coarseness between the *rough* and *bastard*. See FILE.

Mid'dle-post. (*Carpentry.*) A king-post in a TRUSS (which see).

Mid'dle-press'ure En'gine. (*Steam-engine.*) An English term applied by some to a low-pressure or condensing engine, adapted for working at a pressure of steam comparatively high for its class, say 25 pounds or upward to the square inch.

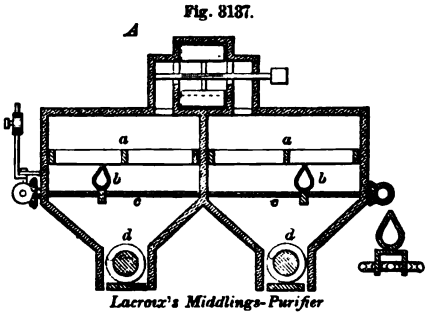
Mid'dle-shot Wheel. (*Hydraulic Engine.*) A *breast-wheel* which receives the water at about its middle hight.

Mid'dling. That portion of a gun-stock between the grasp and the *tail-pipe* or ramrod-thimble.

Mid'dlings-pu'ri-fi'er. (*Milling.*) An apparatus for cleansing the intermediate product of ground wheat termed *middlings*, and separating it from bran on the one hand and fine flour on the other. This was originally effected exclusively by passing the flour delivered from the millstones successively through a series of cylindrical bolts covered with cloth of different degrees of fineness, which were set in rapid rotation and brought in contact with a series of longitudinal rods termed beaters, the bolts separating in succession the finer and coarser qualities of flour and the middlings, the bran being retained within the last cylinder. See FLOUR-BOLT; BRAN-DUSTER.

This was succeeded by the dressing-machine, in which a like cylinder, rotating on an inclined axis, is covered with wire-gauze of several degrees of fineness, the coarsest being placed at the lower end; the flour is thus graded during its passage from the

Fig. 3137.



Lacroix's Middlings-Purifier

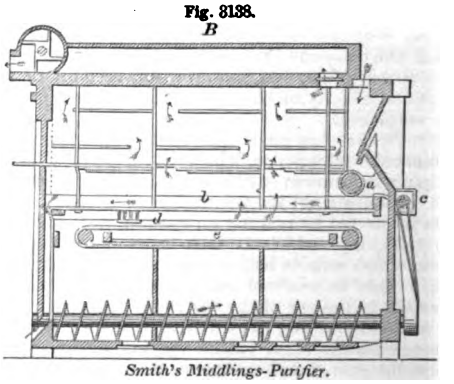
upper to the lower part of the cylinder, the middlings passing through the comparatively coarse meshes of the lower cloth while the bran passes out at the end as tailings. The interior of the cylinder is provided with a revolving reel set with brushes, which force the meal through the meshes of the cloth. When clogged, the cylinder is cleaned by an interior brush operated by the machinery.

As at present constructed, machines of this kind may be divided into five classes, an example of each of which is given.

A (Fig. 3137) is one in which air, forced through perforated pipes, is used for cooling the flour and clearing the meshes of the cloth. The middlings are fed through hoppers over the screens *a a*, and are purified by a current of air passing through the tubes *b b*, which are arranged on the screw-threaded shaft *c c*, alternately rotated in opposite directions, causing the tubes to traverse from side to side of the screens; the lighter matters are drawn upward and carried off by a fan, while the middlings, passing through the screen, are removed by the screw-conveyors *d d*.

Fig. 3138, *B*, is a purifier in which brushes are employed for clearing the meshes of the cloth. The meal or middlings is fed by rollers *a* to the bolt *b*,

Fig. 3138.

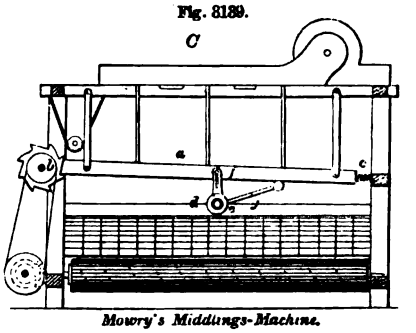


Smith's Middlings-Purifier.

its amount being regulated by a slide; a shaking motion is imparted to the bolt by an eccentric *c* on a shaft, and a continuous upward current of air is passed through the machine; fine particles adhering to the bolting-cloth are removed by brushes *d* attached to endless belts *e*.

Fig. 3139, *C*, shows a machine with reciprocating shakers, with knockers for clearing the meshes of

Fig. 3139.



Mowry's Middlings-Machine.

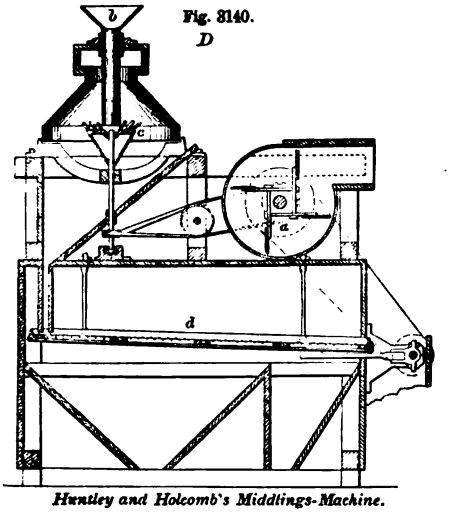
the cloth. In this machine the suspended shaker *a* is pressed against the ratchet-wheel *b* by a spring *c*, the rotation of the wheel causing a vibration of the shaker; *d* is a rock-shaft, pivoted at *e*, loosely connected with the shaker by a slot and pin at *f*, and

Digitized by Google

provided with an arm *g* carrying a hammer, which strikes the bottom of the shaker at each reciprocation.

Fig. 3140, *D*, shows whippers or beaters in connection with an air-blast for operating on the mid-

Fig. 3140.
D

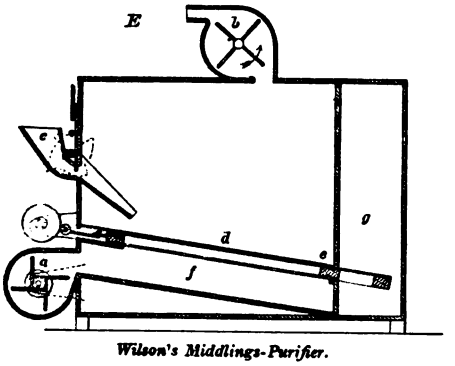


Huntley and Holcomb's Middlings-Machine.

dlings before bolting. A fan *a* produces an air-blast which is carried upward through an inclined trunk; middlings from the hopper *b* are caught by a revolving cone or disk *c*, provided with upwardly projecting pins, disengaging particles of dirt which adhere to the coarser particles of the meal; these are carried off by the blast, while the valuable portions slide down an incline to the sieves *d*, which are vibrated in the usual manner by a cam-shaft; the coarser and harder portions of the meal fall through the sieves, while foreign matters are finally shaken out at their ends and delivered into a spout.

E (Fig. 3141) uses both suction and an air-blast. In this machine a blower *a* and exhaust-fan *b* are employed; the stuff from the hopper *c* is fed inter-

Fig. 3141.



Wilson's Middlings-Purifier.

mittingly to the screen *d* by means of a cut-off plate, while the screen has a longitudinal motion, and is divided into two parts by a partition *e*, one part being immediately over the air-tight chamber *f*, while the other projects within the air-tight chamber *g*; the first part is provided with cloth of such fineness that none of the middlings can pass, but the other allows the granulated portions to pass to a spout, by which they are conveyed to a receiver; the tailings fall over the lower end of the screen into another receiver.

The fine particles of dust and dirt are driven upward by the blower *a* and carried away by the exhaust-fan *b*. See "Digest of Middlings-Purifiers," DeW. C. Allen, Washington, 1873.

Mid-feath'er. (*Steam.*) A water-bridge in a steam-boiler furnace which occupies a middle position in the flue-space, the flame passing both above and below it.

Mid'ship-beam. (*Shipbuilding.*) The longest beam in the middle of a ship.

Mid'ship-bend. (*Shipbuilding.*) The *midship-section* or the largest of the cross-sections of a ship. When the middle of the ship has a portion of a uniform cross-section, such is called the *midship-body.*

Mid'ship-frame. The frame at the midship or largest section of a vessel.

Mil'i-ta-ry-bridge. A bridge, usually of a temporary character, designed for the passage of an army with its artillery and supplies or for maintaining its communications.

Probably the earliest on record is that thrown by Darius across the Bosphorus during his invasion of Greece, 490 B. C.

Ten years later, his successor, Xerxes, crossed his army, said to have been 1,700,000 strong, from Asia into Europe by similar means.

The bridge of Xerxes across the Hellespont consisted of ropes resting on galleys and supporting planks. The account given by Herodotus may be thus briefed: —

Two parallel bridges were constructed, one supported by 360 vessels and the other by 314. The vessels are classed as *triremes* and *penteconters*, and were anchored parallel, the prows facing up stream, that is, toward the Euxine. To each bridge were assigned six cables, "two of white flax and four of papyrus." These were stretched across the strait, lying upon the vessels, and drawn taut by wooden capstans on the Abydos and Chersonese shores. One bridge was for the army, and the other for the sumpter animals. "Trunks of trees were sawn into planks, which were cut of a length to suit the width of the bridge, and these were laid side by side upon the tightened cables and then fastened on the top. This done, brushwood was brought and arranged upon the planks, after which earth was heaped upon the brushwood and trodden down solid. Lastly, a bulwark was set up on each side of this causeway of such a hight as to prevent the sumpter beasts and the horses from seeing over it and taking fright at the water." — HERODOTUS, VII. 36.

The army was seven days and nights in crossing.

The bridge thrown across the Rhine by Cæsar, for the purpose of enabling him to cross that river in order to chastise the Germans, who, under their king, Arioristus, had invaded the Gallic territory, was formed by driving piles 18 inches square into the bed of the river, in pairs 2 feet apart and slightly inclined. Opposite these, at a distance of 40 feet, was another pair of piles, inclined in the opposite direction. These were connected by beams 2 feet in diameter, on top of which were laid joists running in the direction of the breadth of the river, and covered with hurdles to form a roadway.

On the side below the bridge inclined piles were driven, serving as braces against the force of the current; and on the upper side were others to ward off floating objects, as trees or boats. The whole was completed and the army passed over in ten days. See BRIDGE.

Digitized by Google

Trajan's bridge over the Danube, erected 150 A. D., for the purpose of keeping in check the warlike Dacians, was one of the most remarkable structures of antiquity. It was built on stone piers supporting wooden arches, on which the superstructure rested. It was destroyed by his successor, Hadrian, who thought the Roman Empire was already large enough, and wanted no provinces beyond the Danube. The remains of the piers are existing at the present day. See BRIDGE.

Military bridges, of a temporary character, are made with piles, trestles, boats, pontons, or casks.

Pile-bridges are applicable in shallow rivers with deep mud, and where boats are not accessible or the stream not navigable.

Trestle-bridges are applicable under similar circumstances, where the material at hand suits better that mode of construction.

Boat-bridges are made by fastening them alongside each other to a cable moored on each bank of the stream. Over the boats are laid the *balks*, and crossing these the *chesses* or flooring-boards.

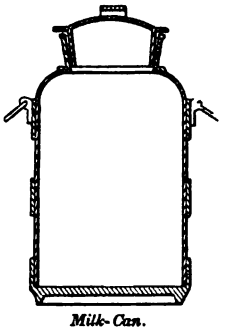
Ponton-bridges are laid upon *bateaux* or *pontons* carried by the army, and forming the *ponton-train*. They are laid like the boat-bridge or anchored.

Casks lashed to spars have been used as *pontons*. See PONTON-BRIDGE; TRESTLE-BRIDGE.

That end of the bridge toward the enemy is protected by a fortification (a *tête de pont*), a redan, or redoubt, according to the nature of the ground, and when practicable, by batteries arranged to command its approaches.

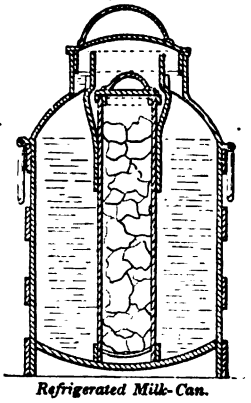
Milk-can. One adapted to the jars and blows incident to the conveyance of milk to market and to customers. In the example, the sheet-metal portion has strengthening bands, and is riveted to a cast-iron bottom, on which it may be rolled without bruising.

Fig. 3142.



Milk-Can.

Fig. 3143.



Refrigerated Milk-Can.

Fig. 3143 shows a can with an interior removable ice-chamber. This has a closely fitting stopper, secured in the can by a flange at the bottom, an annular band at the top, and springs to keep it in place. The inner vessel is filled with ice to keep the milk cool.

Milk, Con-densed'. Recipes for preserving milk: —

1. Add sugar; evaporate to one fourth; solder in cans.

2. Add carbonate of soda and white sugar; evaporate to dryness; cut into cakes.

3. Add sugar and alkali; evaporate to dryness; crush, powder, and bottle.

4. Evaporate to one half; beat up with white of egg; simmer, skim, strain, and boil.

English recipe, 1856. Fresh skimmed milk, 1 gallon; sesquicarbonate soda, 1½ drams; mix, evaporate to ½ by steam-bath, accompanied by agitation; add powdered white sugar, 3½ pounds; complete the evaporation and reduce the mass to powder; add the cream, incorporate, and seal hermetically.

Old recipe. Carbonate soda, ½ dram; water, 1 fluid ounce; dissolve; add fresh milk, 1 quart, sugar, 1 pound; reduce to a sirup in a steam-bath, and finish the evaporation on plates in an oven.

At the works of the Aylesbury Condensed Milk Company in England 200 persons are employed, and the milk of 1,200 cows, each yielding 14 quarts, is daily evaporated. The milk is brought in tin cans by the surrounding farmers, is tested by taste, smell, and the lactometer, partially evaporated in a vacuum-pan, mixed with sugar, and finally condensed until its original proportion of water, 87 per cent, is reduced to 25 per cent. The condensed liquid has a semi-fluid consistence, and the "Lancet" gives the following analysis: —

Water	25.10
Butter	11.73
Caseine	15.17
Milk-sugar	16.24
Cane-sugar	29.46
Ash	2.30
	100.00

Borden's (American) process of condensing milk is protected by letters-patent. There are a number of factories for preparation of condensed milk in and about New York, where it is sold from house to house fresh from the condensing-vats. Thousands of gallons of milk are daily prepared to supply the demand in the army and navy, and for foreign consumption.

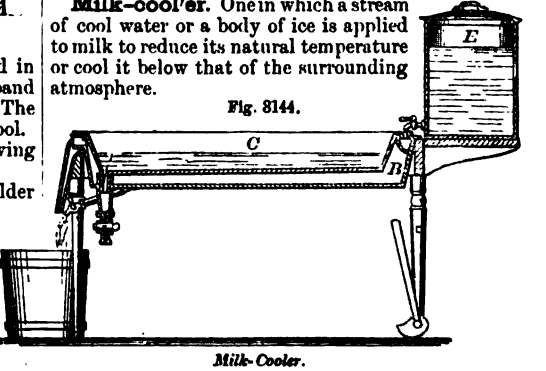
The usual process of evaporation is to place the milk in large shallow pans, each having a pump to exhaust the air. The water is driven off by a steam-heat of about 160 degrees. When the desired condensation is attained, sugar is added if the product is to be preserved beyond a few days, and other chemical agents according to the process.

Pure milk condensed to one third will remain sweet from 5 to 10 days in warm weather.

In Kirchofer's process the milk is not condensed, but as fresh drawn from the cow, is placed in cans or bottles, which are filled as nearly full as possible, immediately hermetically closed, and placed in a bath of water whose temperature is then slowly raised to between 160° and 170° Fah., and kept at this temperature for a greater or less length of time, according to the period during which it is desired to preserve the milk. The fire is then withdrawn and the bath allowed to cool down slowly.

Milk-cool'er. One in which a stream of cool water or a body of ice is applied to milk to reduce its natural temperature or cool it below that of the surrounding atmosphere.

Fig. 3144.

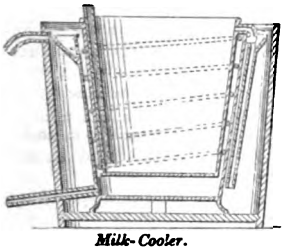


Milk-Cooler.

Digitized by Google

In Fig. 3144, the water from a reservoir *E* passes through the pan *B* beneath the milk-pan *C*, and is discharged into the bucket.

Fig. 3145.



Milk-Cooler.

In Fig. 3145, the milk flows down a spiral track between the two metallic vessels, is cooled in its passage by the contents of the outer and inner vessels, and is discharged.

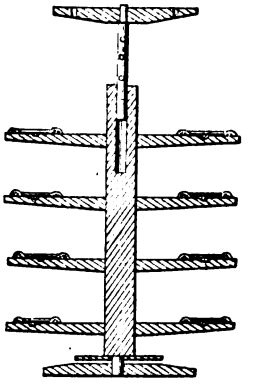
Milk'er. Cow-milkers are of two kinds: one of them depends upon a cannula, which penetrates the lacteal orifice beyond the region of the sphincter muscles, which close the opening and prevent the involuntary emission of the milk; the other depends upon mere pneumatic pressure, the teat being inclosed in a cup whose lower end is connected by a pipe with an air-exhausting apparatus and a vessel to receive the milk.

Colvin's hydraulic cow-milker combines a cattle-stall and compound milking apparatus, operated by power. Several machines are ranged in a row, one to each stall, and are designed to be operated by one attendant. The power runs continuously, and the man allows a cow to pass through and admits another, which is secured in place, and the apparatus attached. The milk runs into large cans partially sunk in the floor. It is said that three machines are sufficient to milk sixty cows in the time it would take six men to milk them by hand.

The milkers are worked by pumps, the pistons of which are driven by power. They are attached by a jointed iron pipe to allow of the movement of the cow forward, backward, or sideways, always adapting itself to her motions. The teat-cups are of corrugated rubber, closely enveloping the teats of the cow. The pumps oscillate, giving the natural motion of the calf in sucking, or of the hand in milking; the space between the elastic diaphragm in the milker and the pump is filled with water, which, in working the pumps, oscillates in the tube and produces a vacuum at each alternate stroke of the piston.

Milk-glass. A kind of glass having a semi-translucent or milky appearance, and known by the names of CRYOLITE-GLASS or FUSIBLE PORCELAIN (which see).

Fig. 3147.



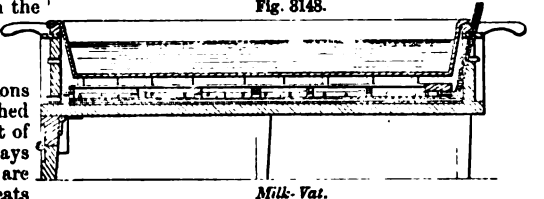
Milk-Rack.

Milk'ing-shield. A protecting plate over the breast, having a perforated cap over the sore nipple, to protect the same against actual pressure by the mouth of the infant when nursing. See NIPPLE-SHIELD.

Milk-rack. A series of shelves in a dairy to hold milk-pans. That shown is rotatable on its axis.

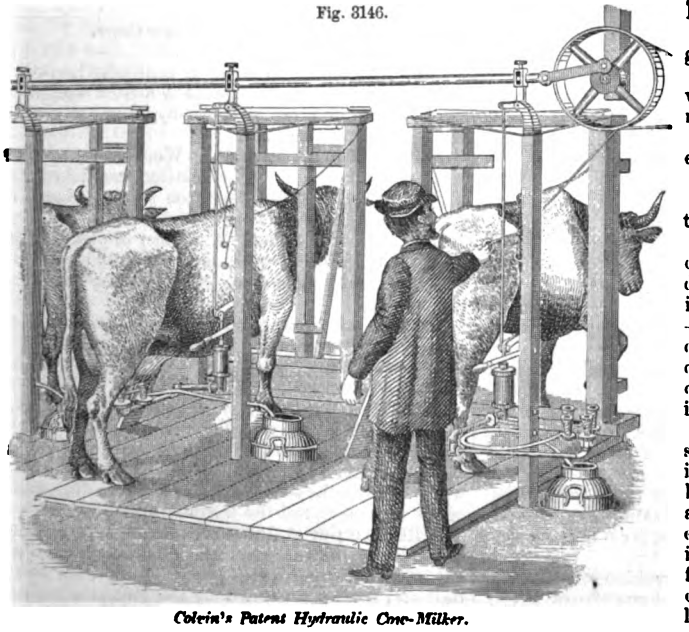
Milk-vat. A deep pan for setting milk to raise cream or curdle for cheese. In the example, steam and water pipes are introduced between the exterior and the interior vats to regulate the temperature of the contents of the latter.

Fig. 3148.



Milk-Vat.

Fig. 3146.



Colvin's Patent Hydraulic Cow-Milker.

Mill. 1. A machine for grinding.

2. A lapidary's grinding-wheel, known as a roughing-mill, cloth-mill, etc.

3. To serrate or dent the edges of coin.

4. To *throw* undyed silk.

5. A building or factory containing machinery.

6. (*Die-sinking.*) The hardened steel roller having the design in *cameo*, and used for impressing in *intaglio* a plate, — as in the bank-note system of engraving; or a copper cylinder, — as in the process of engraving cylinders for calico-printing.

The design is engraved on a small steel plate or roller, which is subsequently hardened by heating it to a cherry-red in an iron case containing pounded bone-ash, and then plunging it into cold water, its surface being protected from oxidation by a chalky paste. This hardened roller is called the

Digitized by Google

die. The *die* is then placed in a transferring-press, where, by rotatory pressure, it is made to impress its design upon the surface of a softened steel roller placed in apposition to the said *die.* The soft roller has the design in *cameo*, is hardened, and forms a *mill*, which is capable of delivering an *intaglio* impression upon a plate or roller, as above stated. The process was invented by Jacob Perkins, and adapted to engraving cylinders for calico-printing by Locket of Manchester, England.

Mill-bar. The rough bar, as drawn out by the puddler's rolls. As distinguished from *merchant-bar.*

Mill'board. A stout pasteboard made of strong materials, such as refuse flax, cotton, and hemp, rope, or bagging; and used for the stiff portion of book-covers, and for other purposes. It is also used for packing between the flanges of pipes, being previously soaked in oil.

A commoner article is made of other coarse fiber, such as jute (cochorus), asclepias, sorghum, bark, straw, bamboo, grass, gama grass, New Zealand flax, and other materials.

Mill'board-cut'ter. A machine for cutting heavy board, for book-covers and pasteboard boxes.

Fig. 3149 shows a machine of this class. The sheets of pasteboard are fed between two shafts which carry disks or knives capable of adjustment at proper distances apart. The board is thus cut into strips, which are divided into parallelograms by a second feeding through the machine.

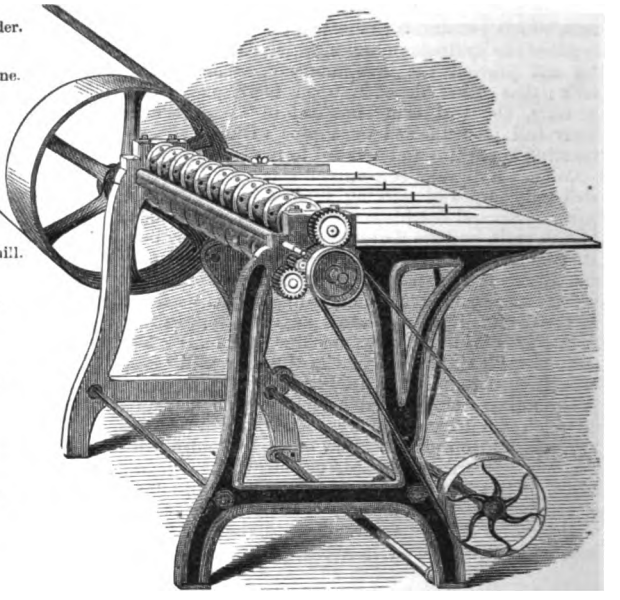
Mill-cake. 1. The incorporated materials for gunpowder; in the cake form, previous to granulating.

2. The mass of hulls and parenchyma remaining after the expression of linseed-oil.

Mill-dam. A wall or bank across the course of a stream to raise the level of the water and divert it into a mill-race. See DAM.

Milled Lead. Lead which has been spread into a sheet in the *rolling-mill*, in contradistinction to lead which is leveled while in a melted condition, upon a table with raised edges by means of a *strike* in the hands of two men.

Fig. 3149.



Chambers's Automatic-Feeding Board-Cutter.

Milled Cloth. (*Fabric.*) Woolen cloth which has been fulled or felted by beating, to thicken it.

Double-milled; the operation having been repeated to increase the density.

Mil'le-fi-o're-glass. A number of pieces of filigree, or tubes of glass enamel, are fused together, their sections representing stars, flowers, and other ornaments.

Sections of these tubes are imbedded in white transparent flint-glass, forming paper-weights.

It is a species of *mosaic* enveloped in a transparent bulb.

Mill-fur'nace. (*Metal.*) A reheating furnace. A furnace where the puddled metal is reheated, preparatory to again passing through the rolls.

Mill-gang. In warping; that part of the warp which is made by a descending and ascending course of the threads round the warping-mill.

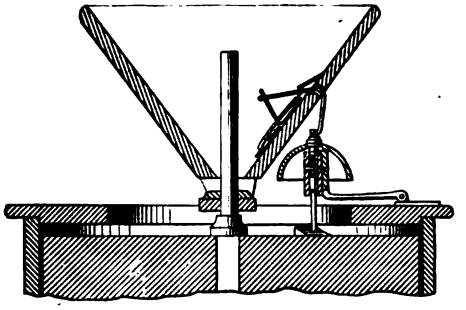
Mill-hop'per A-larm'. An attachment to grinding-mills to indicate that the grist has about run out of the hopper. Mills have been burnt by the heat and sparks generated by the stones when running empty, and several devices have been patented

Digitized by Google

to turn off the power and stop the machinery when the grist is expended. Other patents have been granted for arrangements by which timely notice is given of the fact that the hopper is nearly empty.

In the example, a plate hinged to the side of the hopper is held down by the grist until the latter is about expended. The plate then rises, and its attached cord allows a stud to drop so as to be struck

Fig. 3150.



Taylor's Mill-Hopper Alarm.

by a projection on the stone at each revolution of the latter. This gives a rapid oscillation to the clapper, and sounds the alarm which announces that the grist is nearly expended.

In another case, a bell is so arranged within the hopper that when surrounded by the grain it is held stationary, but when uncovered is caused to ring by the tremulous motion of the hopper. The grain rests upon a float hinged near the bottom of the hopper. When the grain is about expended the float is raised by a weighted lever, and the spout of an upper hopper is opened to supply the lower one with grain.

Mil'li-net. A machine-made net. *Mill-net; bobbinet.*

Mill'ing. (*Machinery.*) 1. As in Webster, so in writers on mechanical construction, the term *milling* is applied: —

a. To an action such as that which upsets the edge of a coin, making the raised flanges which protect the ornaments in relief on the obverse and reverse sides of the coin.

b. To an action such as that which gives a fluting or crenation to the edge of the coin.

c. To a planing action by a circular cutter on metal. A mode of *shaping*.

The first is an expanding or upsetting, and the second is an indenting process, which is properly called *nurling*.

Milling, in the first sense stated, is performed upon an object in a lathe by the pressure of a burnisher or wheel, which turns over or upsets an edge, as in the case of the feather-edge on a tube or bezel which holds a lens or a jewel in its seat or setting.

The term *milling* is also applied to the machines in the mint which turn over the edges, at the expense of the diameter, and thus throw the faces a little into recess, so that the ornamental impressions are protected by the edges, and the coins when piled are enabled to stand steadily. The machine is described in its place under COINING (which see). Castaining's machine for milling coin was introduced into the French mint in 1685. See also *B*, Fig. 3151.

For *milling*, as a mode of planing to shape, see MILLING-MACHINE.

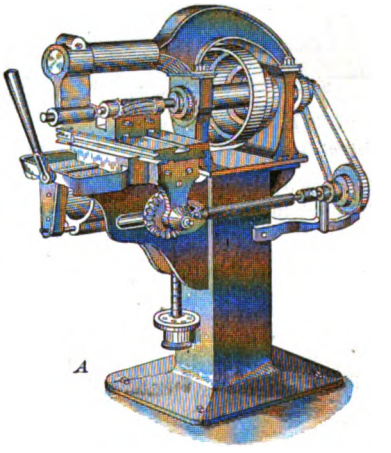
2. (*Porcelain.*) The mastication and grinding of slip for porcelain, giving it the final working to develop plasticity.

3. (*Cloth.*) A fulling process which condenses and thickens cloth at the expense of its area.

Mill'ing-ma-chine'. (*Machinery.*) A machine for dressing metal-work to shape by passing it on a traveling bed beneath a rotating serrated cylindrical cutter. The milling-machine occupies the same relation to metal that the planing or molding machine does to wood. In each case the work is reduced by a rotary cutter, whether the surface be plain or irregular. The use of the *milling-machine* has advanced greatly during the past ten years. They are now used as finishing tools in machinists' shops, but especially in the business of reducing to shape the forged, stamped, or cast pieces which are made by the thousands to an exact gage, and are built up into sewing-machines, fire-arms of various kinds, and other things too numerous to mention, which are made in pieces to size, and then *assembled*. They are largely used for finishing heads of bolts and set screws, shaping nuts, fluting taps or reamers, cutting key-seats.

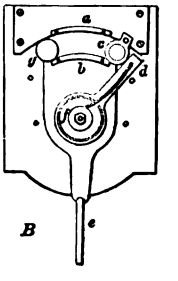
Their use has been much facilitated by the contemporary improvement in grinding-machines with emery-wheels. It has been found that by the use of these grinding-machines, milling-tools could be kept in perfect cutting order without, as was formerly necessary, drawing their temper and retempering. It has thus been rendered possible to greatly widen the application of these tools and to adapt them to work which would have cost much more to

Fig. 3151.



finish by methods formerly in vogue.

A (Fig. 3151) is a machine designed for milling where only a light or medium cut is required. The spindle is driven by a belt running on a cone-pulley without the intervention of gearing. The outboard center is supported by a stout cylindrical arm, secured to the head of the machine. The table is actuated by a hand-feed motion, and a rack and pinion worked by a lever in front constitutes the hand motion.



Milling-Machine.

B (Fig. 3151) is a machine for lettering or milling the edges of coins. In that used in the French mint two arc-dies *a b*, on which the inscription is

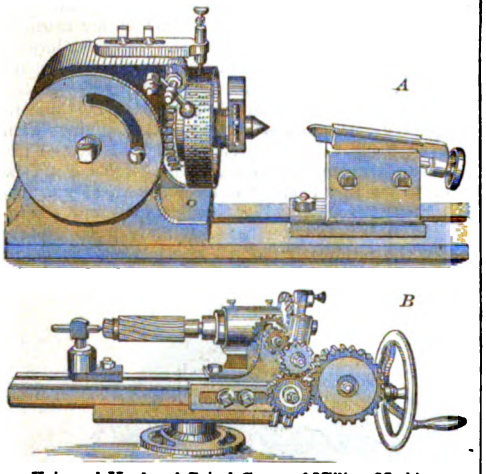
Digitized by Google

engraved in raised letters, one half on each die, but in reverse order, are immovably secured to the plate which bears the machine, and the distance between them is precisely equal to the diameter of the piece to be milled. *c* is a tube containing a pile of coins, which are successively pushed between the dies by the arm *d* attached to the lever *e*.

This lever, by its back and forth movement around the pivot *f*, also causes a rotary movement of the coin between the dies, during which the inscription, in sunken letters, is impressed on its periphery, after which it falls through the aperture *g* into a receptacle.

Fig. 3152, *A*, is a view, on a somewhat enlarged scale, of a *universal head*, which is adapted to be

Fig. 3152.

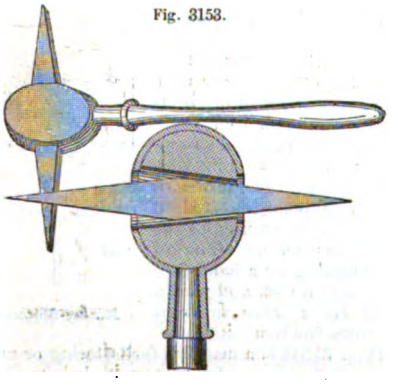


Universal Head and Spiral Cutter of Milling-Machine.

fastened to the platen of the machine. By chucking the object in this head, spur or bevel gear may be cut, and work milled at any angle or in any position.

B, in the same figure, is a *spiral cutter*, also designed to be attached, when required, to the platen of the machine. A piece of work is shown in position. By means of changeable gears the work is rotated beneath the milling-tool, so that a spiral cut is produced instead of a straight fluting. It is constructed to cut spirals 8 inches in length, right or left hand, of any pitch, from one turn in 2 inches to one turn in 6 feet. The spindle is hollow, allowing a $\frac{1}{16}$-inch rod to run through it.

Fig. 3153.



Mill-Picks.

Mill'ing-tool. A small indented roller mounted in a stock and used to nurl objects, such as the edges of screw-heads, by pressure against the latter when they are rotating in a lathe. A *nurling-tool*.

Mill-pick. A miller's tool for dressing millstones, giving to the buhrs the slightly serrated surface; an operation known as *cracking*. The steel is necessarily hard and tough, great skill in heating, hammering, and tempering being required.

Mill-race. The canal by which water is conveyed to a mill-wheel. Below the wheel the water is conducted away by the *mill-tail* or *tail-race*.

Mill-saw Vise. A clamp to hold a mill-saw while filing. It is intended to be bolted to a bench,

Fig. 3154.

Mill-Saw Vise.

and the jaws work on centers to enable the saw to be placed at an angle.

Mill-spin'dle. The vertical spindle of a grinding-mill, on which the runner is supported. See GRINDING-MILL.

Mill'stone. One of a pair of cylindrical stones for crushing grain in grinding-mills. The stone is peculiar, and comes mostly from France and from Georgia. See BUHR-STONE.

Many attempts have been made to introduce metallic cylinders, and stones differing from the buhr, in flouring-mills, but with indifferent success.

The stones are the "bed" and "runner," the upper being usually the moving stone, the lower being stationary. The relation of bed and runner is, however, sometimes reversed, the lower being the runner. See GRINDING-MILL, where illustrations occur.

The runner is supported by a *balance-rynd*, which stretches across the *eye* and rests upon the *spindle*. The upper part of the *spindle* is called the *cock-head*, and it is inserted into a cavity on the under side of the balance-rynd, called the *cock-eye*.

Millstones have various arrangements of grooves on their faces. The grooves are called *furrows*, and the intervening portions of the face are called *land*.

The system of *furrows* and *land* is called the *dress*, and this varies according to the custom of a country or the skill of the miller. Many varieties of dress are patented, and some will be cited presently. See Figs. 3154, 3155.

The *furrows* on the face of the millstone expedite the grinding action. The face of the millstone around the eye is usually somewhat sunken, so as to allow the grain to enter; this sunken space is called the *bosom*.

The *furrows* lead from the *bosom*, around the eye, to the *skirt* of the millstone, that is to say, to its periphery. It may be noted here, however, that in some modes of dressing, the *furrows* grow gradually shallower and disappear altogether before reaching the *skirt*, and leave a continuous *land* on the outer margin of the face.

A principal furrow leading from the eye to the skirt is called a *leader*; the branch furrow departing from the leader, nearest to the eye, is called a *second furrow*; a branch furrow departing from the *leader* nearest to the *skirt* is called a *skirt-furrow*. A *furrow* concave at bottom is called a *gouge-furrow*.

A *furrow* has one steep edge and one slanting

Digitized by Google

edge; the former is called a *track-edge*, and the latter a *feather-edge*.

A *leader* and its branches, occupying a segment of the face of the stone, is called a *quarter*, though not necessarily or usually occupying a fourth part of the face.

The operation of preparing the face of a stone is called *dressing*. Roughing the land face of a stone with a pick-hammer is called *face-cracking*.

The *draft* of a millstone dress is the degree of deflection of its furrows from a radial direction. Thus in a "7-inch draft" the *track-edges* are tangential to a 7-inch circle.

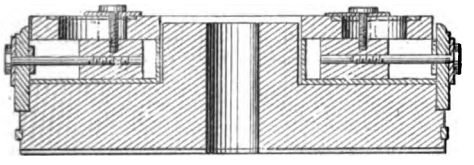
A 12-*quarter* or 14-*quarter dress* indicates a system of 12 or 14 sets of furrows.

One form of lower millstone at the Paris Exposition had sectoral openings covered with wire-gauze, to allow flour to escape as soon as fine enough without compelling it to pass clear to the outside.

The weight of an ordinary pair of millstones is from 1,300 to 1,700 pounds. They measure about 48 inches in diameter, are about 10 inches thick, and contain from 30 to 40 buhrs.

Mill'stone-bal'ance. A weight so placed as to balance other inequalities of weight in a stone, so that it may run true. In the example, weights

Fig. 3155.



Millstone-Balance.

placed opposite to the driving-point and to each other, at the four quarters of the stone, are moved in ways by set screws, operated from the outside on the band, and, being properly adjusted, the true balance is obtained.

Mill'stone-bridge. The bar across the eye of a millstone by which it is supported on the head of the spindle. A *balance-rynd*.

Mill'stone-dress. (*Grinding.*) *a.* The arrangement and disposition of the furrows in the face of a millstone.

b. The draft given to the furrows.

The object of the various kinds of dressing is to secure the proper proportional quantity of material on the stone from the eye to the skirt. The kinds of dress are known as the *quarter dress* and the *circular dress*. In the former the face is divided up into a number of sectors, each of which is known as a *quarter*, and has its own set of furrows. The advance edge of a furrow is the *leading edge*, the other is the *trailing* edge. See GRINDING-MILL.

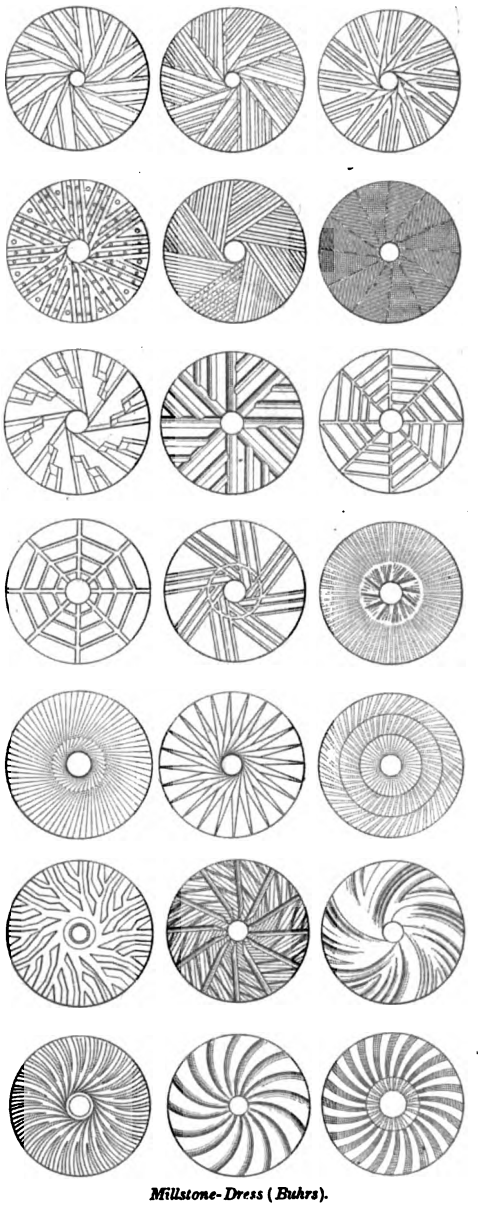
The querns of the Keltic and Roman inhabitants of Britain had notches, forming a *dress*.

Fig. 3156 is a collection of views of different millstones, which will not be described at length. The upper examples are *quarter* dress; then follow specimens of *radial-and-circular* dress, then a number of curved and circular systems.

In addition to the features involving direction are others, such as openings in the bed or runner, forming pockets, or for ventilation, or to allow escape of fine flour. Natcher's patent of 1858 is for ruling lines with a diamond on the *land* of the stone to give it a cutting quality.

In corn and feed mills with serrated iron plates for grinding, the dress is different, as shown in Fig. 3157. Many of these plates are frustums of cones or conoids.

Fig. 3156.



Millstone-Dress (Buhrs).

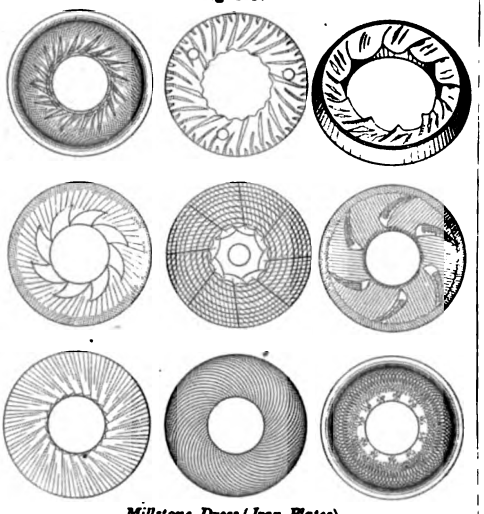
Mill'stone-dress'er. A machine for cutting grooves in the grinding-face of a millstone.

In one form of the machine, the lines radiating from the center are made by a tool raised and dropped by a cam and advancing automatically along a radial arm attached to a central axis.

A Swiss machine for dressing millstones is shown in Fig. 3158. The frame *A* has arms *b b* terminating in feet *c'*, which are provided with set screws. A tool-support *S* is pivoted to the center of *A*, and is adjustable by means of sector *B*, and slides on the arm *C* of the frame. Two disks at *K* carry diamonds

Digitized by Google

Fig. 3157.

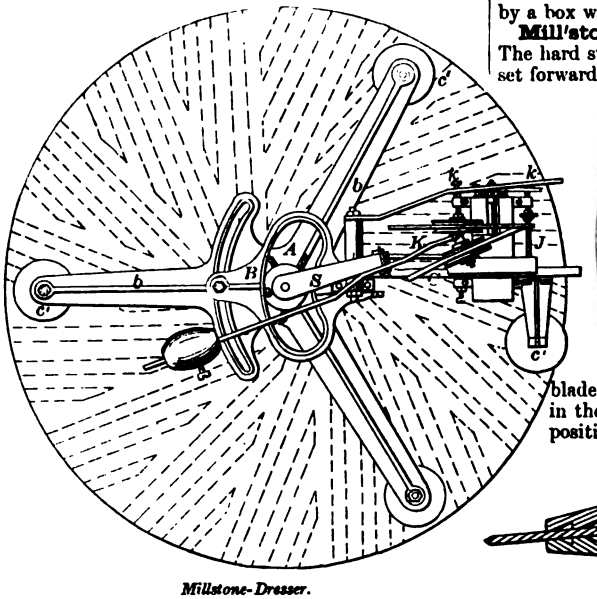


Millstone-Dress (Iron Plates).

or other hard stones on their peripheries, and are set in rapid revolution by belts from spindle *J*, which is revolved from any convenient shaft outside the millstone.

The cutting-disks being put in rapid revolution, the successive blows of the diamonds act in a manner similar to that of a hand tool, and parallel grooves are cut in the face of the stone. Three of these sets of parallel channels or grooves make one division of the stone. The guide-bar *C* is adjustable, so that

Fig. 3158.

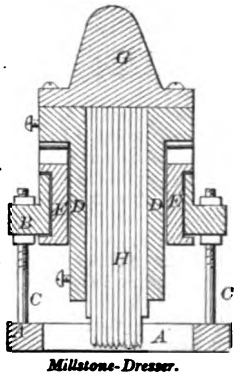


Millstone-Dresser.

the stone may have a right-hand or left-hand dress, as desired.

In the machine shown in Fig. 3159, a number of pick-plates of tempered steel *H* are held in a hollow block *D D*, which latter slides vertically in a holder *E E*. A cap fitting over the pick-plates and secured to the hollow block *G* is struck by a mallet when dressing, while the holder is pushed along on the guide. Standards *C C* with screw-heads permit the vertical adjustment of the holder when the points of the pick-plates become worn. *A A* is the bed, which rests on the millstone when the machine is in use.

Fig. 3159.

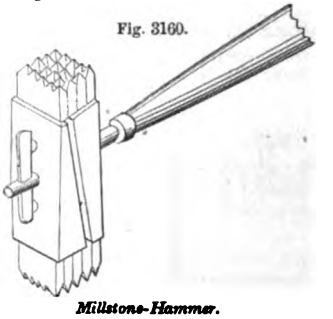


Millstone-Dresser.

Mill'stone-grit. A refractory sandstone of which the sides and hearth of a blast-furnace are composed.

Mill'stone-ham'mer. A tool for furrowing millstones. A millstone-pick. In the example shown, the blades have a central

Fig. 3160.

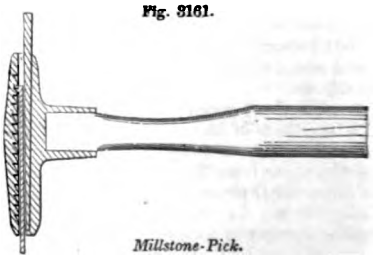


Millstone-Hammer.

hole for the reception of the handle, and are inclosed by a box whose sections have a diagonal junction.

Mill'stone-pick. A tool for dressing millstones. The hard steel blade is held in a stock, and may be set forward as it wears away, a lip on the heel of the

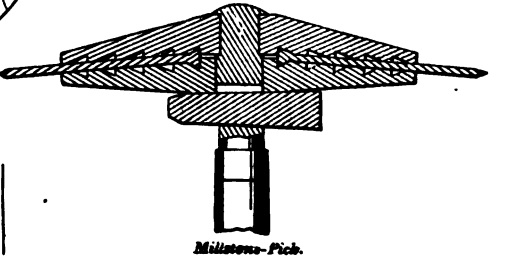
Fig. 3161.



Millstone-Pick.

blade setting in one or another of the notches in the stock. A wedge holds the blade in any position.

Fig. 3162.



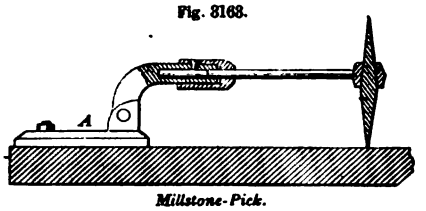
Millstone-Pick.

Digitized by Google

In Fig. 3162 the blades have conical heads, and are held by wedging the portions of the stock together.

Fig. 3163 is hinged to a bed-plate *A*, which slips over the stone while the pick is vibrated.

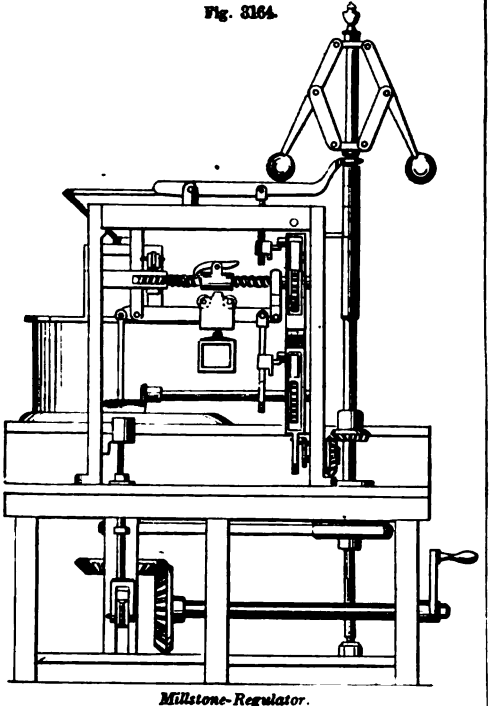
Fig. 3163.



Millstone-Pick.

Mill'stone-reg'u-la'tor. One for graduating the feed of the grain to the rate of motion of the runner. The governor is operated from the mill-gear, and connects, by means of a screw-shaft, a traveling poise, and a scale-beam that will adapt both the feed of the grain and the set of the stones to the varying speed of the runner, caused by changes in the motive power. When the mill is set to grind a particular grade of flour, if the motive power fails to exert the same force on the stone, the governor at once reduces the feed, so that the grade may be continued, though less grain will be ground. The principle is, that the greater the power the greater the capacity for grinding, the feed being increased in

Fig. 3164.

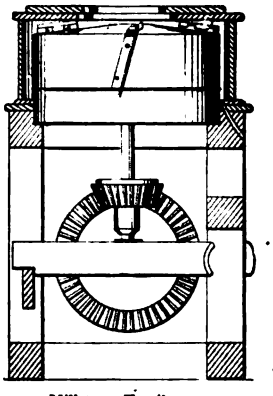


Millstone-Regulator.

proportion the pressure of the runner on the bed-stone must be likewise increased; to do this, the poise is moved in allowing the spindle to sink a little, permitting a larger proportion of its actual weight to rest upon the grain and flour which intervene between the stones.

Mill'stone-ven'ti-la'tor. An arrangement for conducting a blast through the eye of the runner and out at the *skirt*, to cool the floor and facilitate delivery. The invention is described in the patent of Houyet and Gendebein, 1844; and there have since been many variations in the details. In Fig. 3165, the millstones are ventilated, while running, by hinged inclined wings upon the top of the runner, in connection with inclined wings upon the periphery of the stone. See also English patents, 10,163 of 1844, 11,084 of 1846; French patents of Cabanes, May 29, 1845, and May 26, 1846.

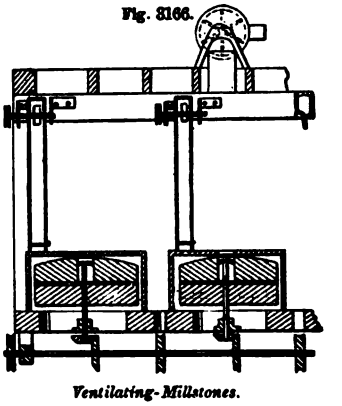
Fig. 3165.



Millstone-Ventilator.

In Fig. 3166, the drums are made air-tight, except at the eye of the stones; the air is exhausted by fans placed in pipes connecting with the sides of the drums, and forced into a cooling-box from which it is drawn off by a large fan.

Fig. 3166.



Ventilating-Millstones.

In Fig. 3167, the devices are shown somewhat more in detail. Air is introduced through an annular duct *T* around the feed-tube *S* into an air-chamber bounded by two cones *M N*, and thence by ducts *P* and spouts *P' P'*, to the space between the stones.

Mill-tail. The *tail-race* of a mill which conducts the water away from the wheel.

Mill-wheel. The water-wheel which impels the machinery of a mill.

For specific index of wheels, see WATER-WHEEL.

See also list under HYDRAULIC ENGINEERING AND DEVICES.

Mill'wright's Com'pass. A dividing and scribing tool used by millstone manufacturers in laying off the dress on the face of stones. See MILLSTONE-DRESS.

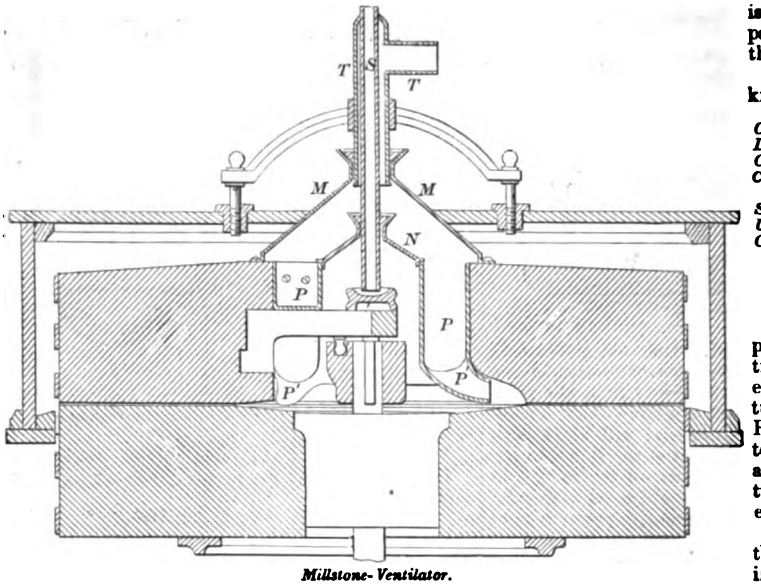
Min-ar'gent. Copper, 1,000; nickel, 700; tungsten, 50; aluminium, 10. The first three ingredients are melted together, then run off in a granulated form, and again melted, adding the aluminium and about 1½ per cent of a flux composed of one part borax and one part fluoride of calcium; these proportions of borax are reduced as the fusion proceeds.

It is one kind of aluminium bronze. (See list of Farmer's aluminium alloys, page 71.) In these copper is the first metal, aluminium the second, and silver, iron, nickel, and zinc in various combinations, so as to give the desired character to the metal, according to its intended duty.

A number of other jeweler's alloys are to be found in a table on page 63; white-metal alloys on same

Digitized by Google

Fig. 3167.

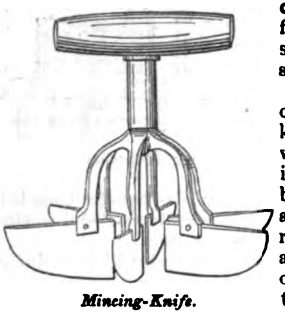


Millstone-Ventilator.

page ; alloys under specific names may be found in the list under METALLURGY.

Minc'ing-knife. A knife with a curved blade or blades for mincing meat and fruit in a wooden bowl.

Fig. 3168.



Mincing-Knife.

Minc'ing-machine'. A machine for chopping food into small fragments. A sausage-machine.

Mincing-machines operate by revolving knives in a barrel which has stationary intervening knives; by guillotine knives acting upon a block rotating on a vertical axis. The *malaxator* or *masticator* is more truly a grinding process, its object being to mash and disintegrate the fibers. See MEAT-CUTTER ; MEAT-CHOPPER ; SAUSAGE-MACHINE.

Mine. 1. A subterraneous passage from which coal, metals, metallic ores, are obtained.

Depth of Mines.	Feet.
Eselchact, Bohemia (silver)	3,778
Dunkenfield, England (coal)	2,504
Pendleton, England (coal)	2,504
Linden, Prussia (salt well)	2,331
Tresavean, England (copper)	2,112
Durham, England (coal)	1,773
Valenciana, Mexico (silver)	1,686
Crown Point, Comstock lode, Nevada (silver)	1,400
Santa Rosa, Mexico (silver)	1,200

2. Crude ironstone, known as *raw*-mine, *green*-mine, *burnt*-mine, etc.

3. (*Fortification.*) An excavation toward or under the rampart of a fortress to contain an explosive charge, to destroy or effect a breach in an enemy's works. Mines executed by the defenders of a fort, to intercept those of the assailants, are *countermines*.

The place of deposit is the *chamber* ; and the passage leading thereto the *gallery*.

Military mines are known as, —

Common. Double. Triple.
Defensive or *countermines.*
Offensive.
Conjunct, several acting simultaneously.
Suffocating or *camouflet.*
Undercharged.
Over or *surcharged*, producing a crater whose radius is greater than the line of least resistance.

Military mining was practiced in very early times. It is represented in the Assyrian sculptures. The Persians and Romans adopted it extensively ; the latter as early as the fifth century B. C. They had no explosives.

Herodotus mentions the Persian mines during the siege of Barca in Libya, and the skillful countermining of the garrison. (IV. 200.)

Mine-cham'ber. The place of deposit of the charge.

Min'er-al Cot'ton. A fiber formed by allowing a jet of steam to escape through a stream of liquid slag, by which it is blown into fine white threads, sometimes two or three feet in length. These threads, though somewhat elastic, readily break up into smaller ones, and, the color of the substance being white, the appearance is that of a mass of cotton.

Being a poor conductor of heat, owing to the retention of air in its interstices, it is suggested as a covering for steam-boilers and pipes.

Min'er-al Tar. Bitumen of a tarry consistence.

Min'er-al Wa'ters. Among the mineral waters are comprised the follows : —

Carrara, blue-lick, carbonic acid, chalybeate, Kissingen, lemonade, potash, Saratoga, seidlitz, seltzer, soda, Vichy. A number of the above are natural waters, but are simulated by adding to water the ingredients in the proportions of the natural, as ascertained by analysis.

Iron, sulphur, lime, soda, magnesia, lithia, are the usual ingredients of the natural mineral waters. The ingredients principally used in the artificial are, carbonic acid, carbonates of soda and magnesia, bicarbonate of potash, chloride of sodium, salts of iron, tartaric acid, tartrate of soda.

"The water was cool enough [a spring in the vicinity of Tolon Noor], but had a pungent hydrochloric odor, reminding me of some I had once drank in the Pyrenees, and which was so very nauseous and ill-smelling that it was sold in the chemists' shops in France at 15 sous a bottle." — *Abbé Huc's Travels in Tartary.*

The passage in Genesis xxxvi. 24, properly rendered, favors the opinion that Anah made the discovery of warm mineral springs in the wilderness while hunting for the asses of Zibeon, his father. Moses records the fact as sufficiently worthy of mention, and it is probable that in the intervening 300 years they had acquired considerable notoriety in the cure of chronic complaints. See Dr. Thompson's "Researches in Palestine."

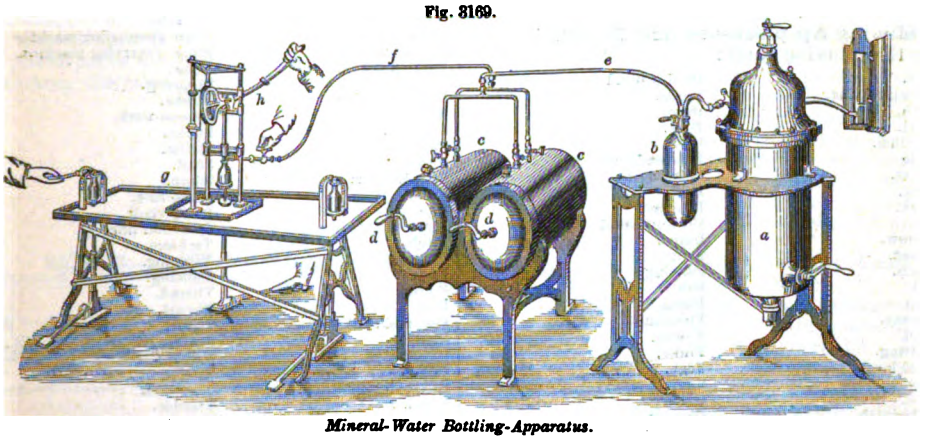
Digitized by Google

Berzelius, the Swedish chemist, a yearly visitor to the Carlsbad waters, is believed to have been the first to make a successful imitation of mineral water. Struve did the same shortly afterward. The first manufactory was established by Goser, an apothecary at Geneva, about 1790, who sold annually 40,000 bottles of Seltzer. Struve soon decided to devote himself to this speciality, and obtained patents in the chief European countries.

In the modern process of manufacturing mineral waters, carbonic-acid water is first made. The various chemicals are dissolved in a certain order, and some notable ingredients are produced by resulting chemical combinations, as, for instance, in a water containing chloride of sodium and carbonate of baryta, the latter would by itself dissolve with great difficulty, so that chloride of barium and carbonate of soda are introduced instead. By chemical reaction the chlorine and carbonic acid change places. By this means phosphate and fluate of lime, flint, compounds of barytes, silicates, and other very insoluble materials may be dissolved. The chemicals are usually grouped together before being placed in the water; thus each spring requires two, and sometimes more, separate solutions or mixtures. These concentrated solutions are largely made by Hanbury Smith and others, and are sold to druggists with directions for use. The price of these solutions to the retailers is $1 per quart, sufficient to make five gallons, or eighty glasses. The cost to the retailer is about three cents per glass, for he must have an apparatus for the aëration of the water. The subject belongs to our scheme only as far as the apparatus is concerned. See AËRATED WATERS.

The accompanying engraving represents a full set

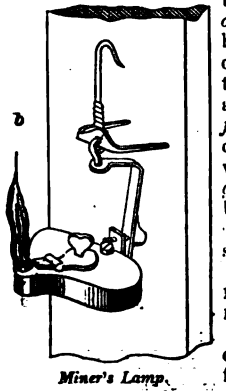
Fig. 3169.



Mineral-Water Bottling-Apparatus.

of apparatus for the manufacture and bottling of mineral water. *a* is the gas-generator, which has an opening at top for introducing the chemicals, and at bottom an agitator and crank; it is also provided with a safety-valve and pressure-gage. From the generator the gas passes into the purifier *b*, containing a re-agent for absorbing other gases from the carbonic acid, and is thence conducted by the pipe *e* into the tin-lined copper fountains *c c*, containing the water to be aërated; these have cranks *d d* operating agitators in order to hasten the absorption of gas. The pipe *f*, provided with a cut-off cock, conducts the aërated water to the bottling bench *g*, where the cork is inserted by depressing the lever *h*, and wired by the device seen to the left of the bench. See AËRATOR; CORKING-MACHINE; BOTTLING-APPARATUS.

Fig. 3170.



Miner's Lamp.

Mineral water may be corked from common soda-fountains with nearly the same facility as from an apparatus constructed for this purpose.

Min'er's Ham'mer. A form of hammer for the use of the miner. Some are shown at *h i j*, Fig. 3178.

Min'er's Lamp. In mines not subject to the collection of fire-damp unprotected lights are used. *a b*, Fig. 3170, are suspensory lamps of the French coal-mines. In many of the German mines the candle is carried on the front of the hat; in some others in a sconce; in others in a cleft stick. Customs vary.

Min'er's Pick. A form of pick or mattock used by miners. *a b c d e f g k l*, Fig. 3178.

Min'er's Shov'el. A form of shovel for miners. (*a b*, Fig. 3171.) See also *p q r*, Fig. 3178.

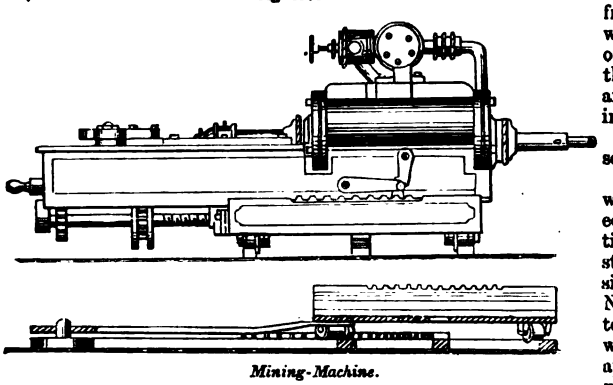
anthracite or bituminous coal or coke. It will pass curves of twenty-five feet radius, and haul on a level track in good condition three hundred and forty tons of cars and load.

Min'ing-ma-chine'. An apparatus provided with picks or cutters to cut grooves in rock or coal, after which the material is to be pried out or detached by wedges, as in coal-mining and working quarries.

In Fig. 3173, the engine moves on a track parallel with the breast of coal or stone, and a forward adjustment is made after each traversing cut. The chisels are worked alternately by their respective engines, their stocks being connected to a walking-beam, and have weighted pistons sleeved upon them. The steam is changed as the piston passes a certain point, and is the means of working the valve. The walking-beam actuates

Fig. 3173.

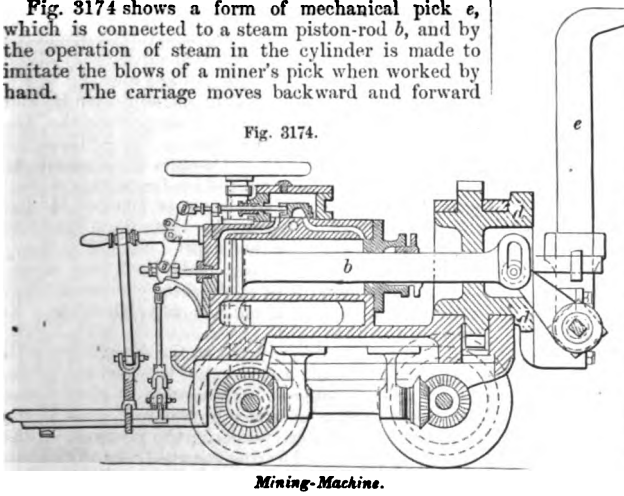


Mining-Machine.

the traversing devices. The blow of the chisel is similar to that of a drill.

Fig. 3174 shows a form of mechanical pick *e*, which is connected to a steam piston-rod *b*, and by the operation of steam in the cylinder is made to imitate the blows of a miner's pick when worked by hand. The carriage moves backward and forward

Fig. 3174.

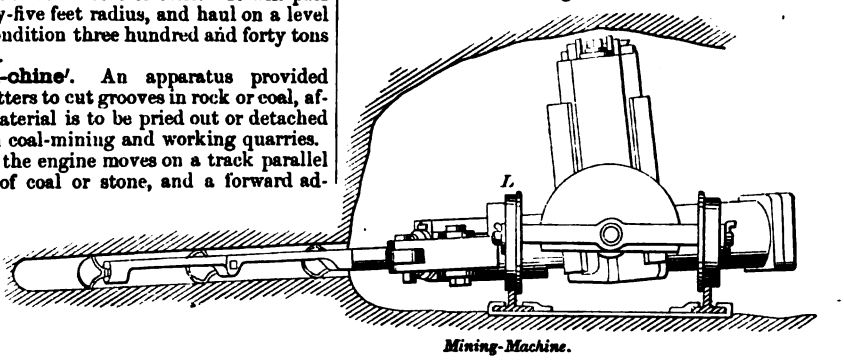


Mining-Machine.

on wheels, and the pick or cutter slides sidewise in the ways *d d*.

The machine shown in Fig. 3175 is operated by

Fig. 3175.



Mining-Machine.

hydraulic pressure, in the cylinder *L*. The hydraulic engine gives a steady thrust-motion to the tools; the position of the machine during the thrust is maintained by a holdfast, which is pressed against the roof during the cutting action of the tool or tools, and released therefrom to allow the machine to move forward during the return or back stroke of the tool or tools; the movements of this head or feeler and those of the drill are obtained from the pressure of water in the cylinder.

For other machines of this character, see COAL-MINING MACHINE.

Min'ing-pump. Pumps for mines and water-works have been on the most extended scale, and the former were for a long time the principal objects upon which the steam-engine was employed. The successive improvements of Worcester, Savary, Newcomen, and Watt were all directed toward one object, that of lifting water, which preceded by many years the useful application of the steam-engine to the purposes of locomotion, either upon land or water. The mines of Cornwall (which were worked by the ancient inhabitants, 3,000 years ago) were drained by means of the Savary apparatus and the atmospheric engines of Newcomen. Here also Watt and Boulton sent their engines, with such a guaranty of comparative economy in fuel, that they agreed to take as pay the value of one third of the proved saving of coal as compared with the Newcomen engine. This saving was found to be 75 per cent, and amounted to $ 35,000 yearly. The Cornish miners succeeded in cheating Boulton and Watt out of the greater part of their dues, and became rich. See STEAM-ENGINE.

At the present day the Cornish pumping-engine stands at the head of the list in effective economical performance, and the "duty" is reported in tabulated form, monthly. See DUTY.

The useful effect of the Cornish pumping-engine has been more closely observed and recorded than that of any other engine.

When Boulton and Watt's patent expired, the best of their engines in Cornwall were doing an

Digitized by Google

average duty of 24 millions of pounds of water raised 1 foot high by 112 pounds of Welch coal.

The rate deteriorated for a while, owing, it is said, to the absence of Mr. Murdoch and some other highly skillful men. Mr. Murdoch will be recollected as the great gas-engineer, and a successful builder of a locomotive in early times.

Captain Lean is credited with a general advance which soon afterward took place.

The tabulated results for the years 1812 – 1843 are as follows: —

Year.	No. of engines.	Average duty.	Average duty of the best engine.	Year.	No. of engines.	Average duty.	Average duty of the best engines.
1812	21	28.0		1828	67	44 1	91.4
1813	29	28.2	31 4	1829	53	49.6	91.6
1814	32	24.5	38.1	1830	56	51.5	92 8
1815	35	24.4	34.1	1831	53	51.6	84.6
1816	35	27.4	38.6	1832	59	52.6	101.1
1817	35	31.5	49.5	1833	56	55.4	100.3

* Wolf's and Grose's improvements.
† Wolf's combined double-cylinder engine, cut off at one-tenth stroke. United mines at Gwennap.

The following table, compiled by S. Hughes, C. E., gives the duty of a number of pumping-engines in different large cities on each side of the Atlantic: —

Duty of Condensing Pumping-Engines.

	Millions of lbs. raised 1 ft. high by 112 lbs. of coal.
East London Water-Works, single-acting Cornish engine, 1836	105.7
East London Water-Works, Boulton and Watt	46.6
Haarlem Mere, Holland	89.4
Average of 36 Cornish engines, 1843	71.5
Cincinnati direct-action	53.6
Buffalo Cornish bull engines	37.0
Boulton and Watt's non-expansive rotative engine, Albion Mills, London, 1786	25.8
Spring Garden, Philadelphia, 1832	24.6
United States Dry-Dock engine, Brooklyn	22.4
Grand Junction Water-Works engines in 1849	46.8
Southwark and Vauxhall engines in 1849	69.6
Beardmore's exemplar Cornish engine	83.4
Beardmore's duty of Cornish engines at London Water-Works	56.25
Fowey Consols 50-inch cylinder-engine of 103-horse power, experimented on by Mr. Wicksteed, and worked at a power of 26½ horses	130.2
Holmbush 80-inch cylinder = 251 horses, worked at a power of 62 horses	122.4
Estimated duty of 72-inch cylinder condensing-engine for Brooklyn Works	35.5
Engines at the East London Works in 1850 from Mr. Wicksteed's evidence	63.8
Engines at the same works before the use of the Cornish engines	26.9
Average duty of Cornish engines (Lean, 1854)	53.7
Duty of best engine, from Lean, 1854	77.0
Duty of Cornish engine (Browne, 1855)	69.7
Duty of best engine, from Browne, 1855	101.4
Pittsburg high-pressure non-condensing engines, 1852: —	
Upper Water-Works	19.9
Lower Water-Works	19.1
Allegheny City	19.2
Detroit	17.3
To which may be added, —	
Worthington duplex engine, Newark, N. J.	76.6
Brooklyn, N. Y., double-acting beam, No. 1	60.1
Brooklyn, N. Y., double-acting beam, No. 3	72.0
Philadelphia, Spring Garden, Cornish	58.9
Belleville, Jersey City, Cornish	62.8
Hartford, Conn.; crank. Mean of three experiments	61.7
Cambridge, Mass.; double-cylinder. (Mean)	67.2

In considering the above, it must be recollected that the quality of coal varies, and the bushel may vary in weight; calculations have unfortunately been made at 94, 100, and 112 pounds.

See also COMPOUND ENGINE; DUPLEX ENGINE; DRAINING-ENGINE; PUMPING-ENGINE.

Cost of raising Water by Steam-Power.

	Gallons.	Hight in feet.	Cost.	Coal per 2,240 lbs.
East London Water-Works	1,000,000	100	$3.00	$2.52
Liverpool	1,000,000	100	4.08	
Wolverhampton	1,000,000	100	8.40	1.80
Southwark	1,000,000	100	2.88	2.40
Grand Junction	1,000,000	100	5.52	3 84

Of the pumps for mining purposes may be cited, (1) the common lift-pump, made on a scale proportionate to its work, but in no essential respects differing from that in ordinary use. Its piston is a valved bucket, being perforated for the passage of the water. See LIFT-PUMP; CORNISH ENGINE.

(2.) A lifting-pump with a plunger; that is, one not perforated, but acting as the ordinary piston.

The piston *b* (see *A*, Fig. 3176) works in a barrel *a*, communicating by a passage *d* with a valve-chamber *e*, to which are attached the supply and discharge pipes *i h*. The chamber has two valves *g f*, which act as induction and eduction, — one opening to admit water from the well as the piston descends, and the other allowing the water to escape into the discharge-pipe as the piston ascends.

The illustration is from Combe's work on mines, and represents a pump erected by Juncker at Huelgoat. It raises water to a hight of 508 feet, and is calculated to raise it a farther distance of 246 feet when the mine reaches that depth.

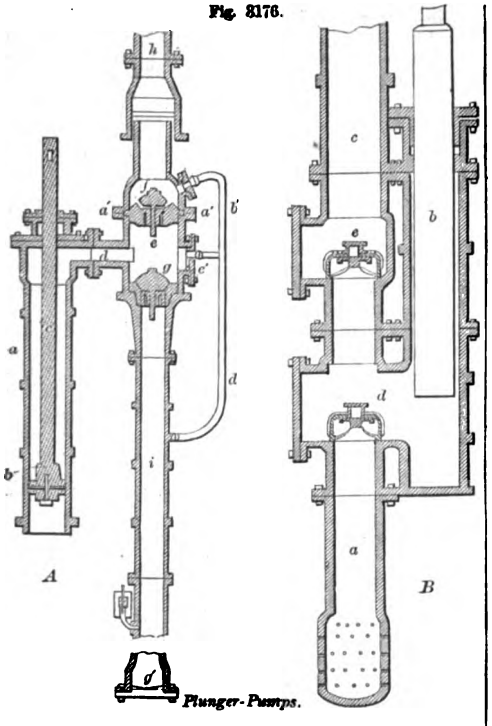
The small pipe *b' c' d* is provided with stop-cocks, and is for the purpose of establishing communication between the pipes *h i* and the valve-chamber *e* in starting the pump.

A small side-valve is fitted to the descending pipe *i*, and loaded with a weight equal to about the pressure of the atmosphere. This valve is placed just above the surface of water in the well, and if the valve *g* does not shut properly, the pressure of the water which is raised during the up-stroke of the piston is transmitted to that contained in the descending pipe and causes the small valve to open.

By means of this, also, it can be ascertained if the upper valve *f* closes properly. For this purpose, the pump must be stopped and the valve-chest put in

Digitized by Google

Fig. 3176.

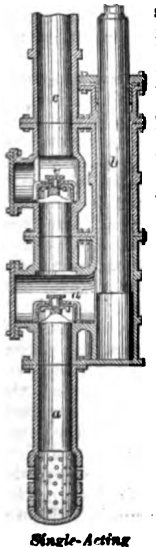


Plunger-Pumps.

communication with the descending pipe, by opening the stop-cocks in the small pipe *c d*. Then, if the valve *f* closes imperfectly, the water from *h* will come through it and fill the descending pipe *i*, raising the small valve. This effect will, of course, not take place unless the foot-valve *g* is in order, — a fact which can be readily ascertained.

B (Fig. 3176) is a section of a force-pump, with solid plunger-piston, such as is commonly used for raising water from mines, rivers, and wells. *a* is the suction-pipe, *b* is the solid plunger-piston, shown near the bottom of its stroke, *c* is the ascending pipe going to the top of the well, *d* is the lower valve-chest, and *e* the upper valve-chest. The valves are double beat. When *e* is open in consequence of the descent of the piston having forced up the water and raised it into that position, the same pressure closes the valve *d*, which then sustains the whole pressure of the column in *c*. See Fig. 3177.

Fig. 3177.



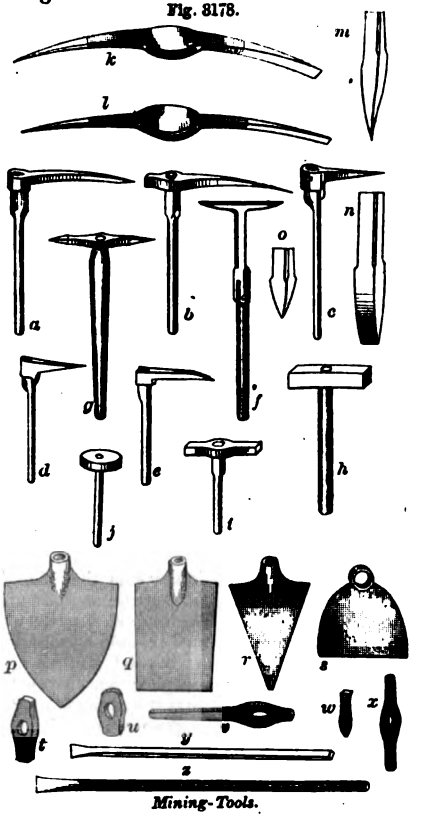
Single-Acting Plunger-Pump.

The plunger is raised by the pressure of the steam on the piston in the steam-cylinder; and as the cover of the pump-barrel through which it works is perfectly air-tight, no air can pass in from the outside to supply its place. A partial vacuum is therefore formed, which is supplied by the air beneath the lower valve and between this and the water. After each stroke this air becomes more and more rare, and the vacuum more and more perfect; till at length the water in the well, pressed by the atmosphere outside, follows the ascent of the piston, and rises through the foot-valve into the pump-barrel. When this is full of water, the plunger descends and presses on the water, which can neither go back through the lower valve nor escape through the cover of the pump-barrel. It can only escape through the valve of the ascending pipe, each successive stroke of the plunger sending into the ascending pipe a quantity of water equal to the volume of the plunger. This goes on till the ascending pipe is full, and then, at each stroke, it delivers a quantity equal to the volume of the plunger.

Min'ing-tools. *a b c d e f g*, forms of miner's picks.

h i j, miner's hammers. *k l*, long picks. *m n o*, miner's wedges. *p*, sharp-point shovel. *q*, square-point shovel. *r*, *bulling*-shovel for dressing ores. *s*, Spanish hoe. *t*, sledge for breaking ores. *u*, mallet for striking borers (*y z*). *v*, pick for driving gad. *w*, steel gad for wedging off pieces of stone. *x*, cobbing-hammer, used in the mines for breaking ore. *y z*, borers for jumping holes to receive blasting-charge.

Fig. 3178.



Mining-Tools.

Min'ion. 1. (*Printing.*) A size of type between Nonpareil and Brevier.

Nonpareil, 148 ems to the foot.
Minion, 123 ems to the foot.
Brevier, 112 ems to the foot.

2. (*Ordnance.*) An old 4-pounder gun, about 7 feet long.

Min-ion-ette'. A small fancy type.

Min'i-um. Red lead.

Mint. A place where bullion is made into coin. See COINING.

Digitized by Google

Mint'age. Duty paid for coining.

Mint'ing-mill. A *coining*-machine. See COINING.

Min'ute. 1. The sixtieth part of an hour.

2. The sixtieth part of a degree.

3. The sixtieth part of the lower diameter of the shaft of a column.

Min'ute-glass. The sand-glass running sixty seconds. *Half*-minute and *quarter*-minute glasses are used at *heaving the log*.

Min'ute-hand. The hand pointing to minutes on the dial of a clock or watch, and traversing the circle in one hour.

Min'ute-jack. (*Horology.*) A fanciful little figure in some clocks which strikes the gong at the prescribed times.

Min'ute-wheel. (*Horology.*) One of the wheels placed between the pillar-plate of a watch and the dial. Also called a *dial-wheel*.

Mir'ror. Mirrors are mentioned in the Book of Job (chap. xxxvii. verse 18), and Moses relates that the brazen laver or washing-basin was made from the mirrors of the women who assembled at the door of the tabernacle of the congregation (Exodus, chap. xxxviii. verse 8).

The ancients had drinking-vessels, the insides of which were cut into mirrors so disposed that the image of the person drinking from them was seen multiplied. A weighty silver cup of this description was presented to the Emperor Probus, when a tribune, by Valerian.

The mirrors of Egypt were of bronze, which, in certain proportions of copper and tin, is called by Ure the whitest, hardest, most brilliant and refractory of metals. See *speculum-metal* in ALLOYS.

A number of the Egyptian mirrors are preserved in the British Museum. They are from 5 to 14 inches in dimensions. They are generally furnished with handles, carved into ornamental or symbolic forms; resembling a tress of hair, a hawk's head, a column, a lotus scepter, or the goddess Athor. Several specimens may be seen in Abbott's collection in the possession of the New York Historical Society.

The mirror with a handle is emblematical of Venus, and is represented on the stones in the ruins of Al Hadhr on the Tigris, the Atra of Ammianus Marcellinus.

Silver mirrors were introduced by Praxiteles, 328 B. C.

A famous mirror of antiquity was that placed by Ptolemy Euergetes (247 B. C.) on the summit of the Pharos of Alexandria. The clearness with which distant objects were depicted caused observers to speak of it in exalted terms beyond any reasonable belief. Abulfeda, the geographer, who wrote 1,000 years subsequently, states that it was made of "Chinese iron," which Buffon supposes was steel, but was more probably one of the white alloys for which China was and is so famous. Probably nearly allied to speculum-metal.

The ancients knew, —

1. That the rays of light were projected in straight lines.

2. That the angle of incidence is equal to the angle of reflection.

These were their only contributions to the science of optics.

Alhazen, about A. D. 1100, shed a flood of light on the subject.

Silver is the most powerful reflector, absorbing but 9 per cent of the light (speculum-metal absorbs 37 per cent of the rays), and for this reason, as well as its durability, was largely employed by the ancients for making mirrors. Silver mirrors are enumerated in the Roman laws among other articles of plate; and Pliny, Seneca, and other writers who ridicule the extravagance of the times, tell us that every young woman of that period must have a silver mirror. These mirrors, judging from the specimens in collections of antiquities, were merely faced with a thin sheet of the precious metal.

Pliny speaks of mirrors composed of a mixture of copper and tin, and says that the best were constructed at Brundisium. A composition of copper, regulus of antimony, and lead, the first largely predominating, was also employed. Such stones as were capable of receiving a brilliant polish and reflecting a large proportion of the rays of light were sometimes made use of.

Mirrors of stone were found among the Peruvians when first visited by the Spaniards. Some of these were made of a black, somewhat transparent, vitrified lava, called by the Spaniards *gallinazo*, similar to the obsidian stone employed by the Romans for the like purpose. These mirrors were plane, concave, and convex. The Peruvians also made them of a species of pyrites called the Inca's stone, from its being much used in ornaments by the Incas or princes of Peru. Ulloa saw one which was 2½ feet in diameter; but they did not usually exceed 2 to 3 inches. This people had also, it would appear from De la Vega, mirrors of silver, copper, and brass.

The date of the invention of glass mirrors is not certainly known. From the account of Pliny, it would seem that they had been formerly made at the celebrated glass-houses of Sidon. These were probably of a dark-colored glass, having a resemblance to the obsidian stone. Transparent glass having a backing of black foil has also been found. The former of these kinds was inferior to metallic mirrors and was probably superseded by them. From the time of Pliny to the thirteenth century, the subject appears veiled in obscurity, and the first unequivocal mention of glass mirrors similar to those of modern times is by Peckham or Peccam, an English Franciscan monk, who, in a treatise on optics, written about the year 1279, speaks of mirrors of iron, steel, polished marble, and of glass covered on the back with lead, and says that no image was reflected when the lead was scraped off. Roger Bacon and others of that age also make mention of this description of mirror. The process of manufacture was by pouring molten lead or tin on the back of the glass plate.

The method of coating with tin-foil was known as early as the sixteenth century, and at Murano, where it was first practiced, the process was as follows: The tin, hammered into thin leaves, was spread out very smoothly: the quicksilver was poured over it and rubbed into it, either with the hand or a hare's foot; and when the tin was saturated it was covered with paper. The glass, wiped very clean, was then laid above it, and while the workman pressed it down with his left hand, he drew out very carefully with his right the paper between the tin and glass, over which weights were afterward placed.

The Venetians had for a long time a monopoly of the business, and till about the end of the seventeenth century their glasses were met with all over Europe and both the Indies. After that period, the improvements in glass-making in other countries, particularly in France, where it was discovered that glass could be cast into much larger plates than had been before prepared by blowing and rolling, destroyed the ancient supremacy of Venice in this art. An unsuccessful attempt was made in France as early as 1634 to establish glass-houses for manufacturing mirrors, and in 1665 Nicholas de Mayer

Digitized by Google

obtained a patent from the French government, and proceeded to erect works for the purpose. This patent was in 1684 renewed for thirty years, but in 1688 Abraham Thevart succeeded in casting at Paris plates of a size which astonished all who saw them; they were 84 inches long and 50 broad, while the largest of those previously made had not exceeded 45 or 50 inches in length.

Among the more remarkable modern mirrors may be cited several of from 20 to 36 inches diameter. One made by Villette was tested by Drs. Desaguliers and Harris. It was composed of an alloy of tin, copper, and bismuth. It was 47 inches in diameter, and was ground to a sphere of 76 inches radius. Its effects were as follows: —

Tin was melted in	3 seconds.
Cast-iron	16 "
A silver sixpence	7 "
A half-penny of George III.	34 "
Slate	3 "
Granite vitrified	54 "
Copper ore	8 "
Bone, calcined	4 "

Tschirnhausen's mirror was 4½ French feet in diameter; its focus, 12 feet.

It vitrified pumice, slate, tiles, shells, pieces of crucibles; lighted green wood instantly, and dissolved an alloy of lead and tin like so much lard.

Newton's mirror had 7 concave glasses, each 11½ inches in diameter; one in the center, the others encircling it, so as to have a common focus. The diameter was 34½ inches, the focus 22½ inches distant. It vitrified brick in 1 second, and melted gold in 30 seconds.

Zeicher formed his mirrors by pressing disks on a hot convex former, to give them their curvature.

Buffon constructed a combination of 140 plane mirrors, each 4 × 3 inches, on a wooden frame 6 feet square. Three set screws to each mirror gave perfect adjustability, and the result was a vindication of the probability of the statement in regard to Archimedes. With but 24 of the mirrors in focus, he lit pitch and tow at a distance of 66 French feet. By a subsequent arrangement of 168 pieces of plane looking-glass, 6 inches square, he lit beech-wood at 150 feet distance and melted a silver plate at 60 feet.

His final attempts were with a frame of 360 plane mirrors, 8 × 6 inches; and one of 400 mirrors, 6 × 6 inches. Wood was kindled at 210 feet distance, tin melted at 160 feet. See BURNING-GLASS.

Petijean's patent (1856) is for a process of silvering by the use of a compound formed of nitrate of silver, ammonia, and tartaric acid. The solution is applied to a polished glass, and silver is precipitated to the amount of about one pennyweight to each square foot of glass. It is then protected by a dark varnish.

Walker (1869) uses the same ingredients in somewhat different proportions. The surface of the glass is thoroughly polished with whiting and washed with distilled water, when the plate is heated to about 120°, and the solution applied. After the silver is precipitated and dried, the plate is varnished with shellac, and then painted with a compound of red lead and litharge to protect the coating of silver. See SILVERING; PLATINIZING; LOOKING-GLASS.

Mi'ser. A large auger for excavating earth in wet situations, as in sinking holes for pier foundations. It is of cylindrical form, has a protruding lip, to enable it to scrape up the soil as it is rotated, and is lifted to the surface to discharge its load.

Mis-e-re're. A projecting bracket in the under side of the seat of a church stall. It is often more or less ornamented with carvings of leaves and grotesque subjects.

Mis-pick'el. An ore of arsenic combined with iron.

Mi'ter. A joint where two pieces are framed together, matched, and united upon a line bisecting the angle of junction.

The term forms a part of several compound words which follow here.

Mi'ter-block. (*Joinery.*) One arranged for sawing pieces to an angle of 45°.

Mi'ter-box. 1. (*Printing.*) A box in which rules are placed while the ends are cut obliquely, so as to make a miter-joint with another rule.

2. (*Carpentry.*) A trough with vertical kerfs, which intersect the sides at an angle of 45°, to form guides for a saw in sawing the ends of pieces to make miter-joints.

Mi'ter-dove'tail. (*Joinery.*) A form of concealed dovetail which presents only a single joint line, and that on the angle. See DOVETAIL.

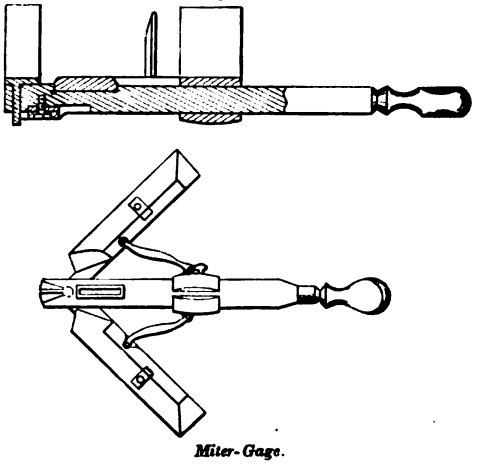
Mi'ter-drain. The transverse drain in the metaling of a road.

Mi'tered. (*Bookbinding.*) Said of fillet ornamentation when the lines unite exactly at their junction without overrunning.

Mi'tered Bor'der. The edging around the slabstone of a hearth.

Mi'ter-gage. A gage to determine the angle of a miter-joint in picture-frames, moldings, etc. Fig. 3179 shows such a gage, having a pair of arms hinged to a stock, on which is a sliding clamp that

Fig. 3179.



Miter-Gage.

carries the saw-guide, which is connected by links with the said arms, so as to allow them to be placed within and conform to any angle, and insure at the same time the proper position of the stock midway between the said arms.

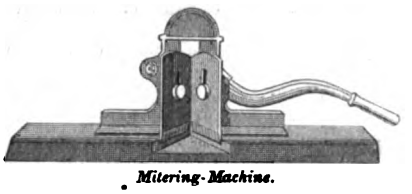
Mi'ter-ing-ma-chine'. 1. (*Printing.*) A machine for mitering printers' rules, so that their ends may meet at a miter-joint. Various adjustments are found in the United States patents.

McDonald, July 3, 1855. Babcock, February 5, 1861.
Grover and Pelouze, May 29, 1860. Walker, December 3, 1867.
Ustich, July 21, 1868.

2. (*Joinery.*) A machine for mitering or slanting the ends of pieces which are to be united by a miter-joint. The machine illustrated is adapted for mitering frame moldings, panel moldings, etc. The irons

Digitized by Google

Fig. 3180.



Mitering-Machine.

work at right angles to one another, and cut the miters true and clean.

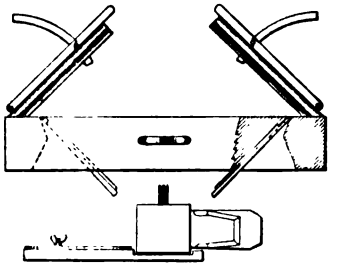
Mi'ter-i'ron. (*Forging.*) A number of bars of angular shape wedged together inside a hoop to form a fagot for a large forging.

Mi'ter-joint. A joint formed by the meeting of matching pieces in a frame, the parts uniting on a line bisecting the angle, which is usually 90°, but not necessarily. See *b c*, Fig. 3182.

Mi'ter-plane. (*Joinery.*) *a.* A plane whose bit is set obliquely across the face of the stock, so as to make a *draw*-cut.

b. A plane running in a race bearing a certain angular relation to the fences or gages which hold and present the stuff.

Fig. 3181.



Miter-Plane.

In the example, the plane works in a groove of the frame and has a cutter at each end. Pivoted adjustable guides hold the stuff at any required angle.

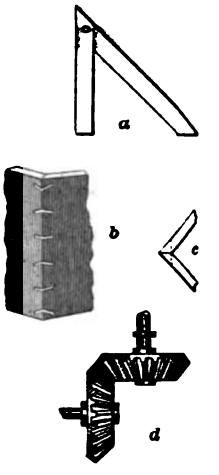
Mi'ter-post. (*Hydraulic Engineering.*) The outer vertical edge of a canal-lock gate, obliquely chamfered to fit against a similar surface on the companion gate.

Mi'ter-sill. (*Hydraulic Engineering.*) A raised step on the floor of a *lock-bay* against which the feet of the lock-gates shut. (See CANAL-LOCK.) The *head miter-sill* for the *head-gates*, and the *tail miter-sill* for the *tail-gates*.

Mi'ter-square. A *bevel-square* whose blades are set immovably at an angle of 45° with each other. The term is used somewhat loosely to denote a square whose blade is adjustable to any angle. A *bevel*.

Mi'ter-valve. A valve whose rim forms with the face of the seat a miter-joint; an angle of 45° with the axis of the valve-disk. See PUPPET-VALVE.

Fig. 3182.



Miters.

Mi'ter-wheel. One of two bevel wheels of equal diameter, and whose working-faces have an equal obliquity to their axes, usually 45°. See *d*, Fig. 3182.

Mi'trail-leur'. (*Fire-arms.*) A French form of battery-gun which is loaded at the breech, by a block containing pockets for a number of cartridges. These are fired consecutively or in a volley. Charged plates are kept in reserve.

The object is to obtain greater accuracy and range than are attainable by the case or canister shot, discharged from cannon. These are contained in an envelope which is ruptured either by a bursting charge within or by the force of projection, and have consequently a tendency to scatter over a considerable area. The mitrailleur, or machine-gun, on the contrary, sends a large number of small projectiles independently, and with precision, to a considerable distance.

Fig. 3183.

French Mitrailleur.

Digitized by Google

The infernal machine with which Fieschi attempted to assassinate Louis Philippe in 1835, and succeeded in killing eighteen persons, including Marshal Mortier, and wounding a large number of others, besides severely injuring himself, was one of the earliest attempts with which we are acquainted for producing a simultaneous discharge from a number of gun-barrels. These were arranged side by side on a bench or stand, and fired by a train, much as in the mode of firing barrels in a proving-house.

That first tried in the French service was made by removing part of the breech from a brass field-piece and inserting twenty-five rifle-barrels, open at both ends, into the bore; these extended back, so that their rear ends were flush with the face of that part of the breech in front of the opening, into which was inserted a case having a number of cylindrical openings equal to that of the barrels, and filled with cartridges; from these, by means of an equal number of plungers operated by a hand-screw, the cartridges were forced into the barrels; the charging-case was then removed, and replaced by a firing-block provided with a lock and pin for each cartridge, by which they were successively fired on turning a cylinder in the firing-block.

A later form of the weapon is shown in Fig. 3183. It has 37 barrels, and ammunition-chests alongside the gun on the same axle. The 37 cartridges, intended for one charge, are contained in a small box. A steel plate with corresponding holes is placed on the open box, which is then reversed, and the cartridges fall points foremost into their respective holes. They are prevented from falling through by the rims at their bases. The loaded plate is then introduced into the breech-slot, and when the breech is closed by a lever, a number of steel pins, pressed by spiral springs, are only prevented from striking the percussion arrangement in the cartridges by a plate in front of them. When this case is moved slowly by a handle, the cartridges are fired one by one. If the plate be withdrawn rapidly, they follow each other so quickly that their discharge is all but simultaneous.

The projectile weighs 37 grammes, or a little over an ounce. The charge of powder is from 6 to 8 grammes. The last amount is that counseled by the inventors.

The mitrailleur of 37 barrels weighs 180 kilogrammes, or 400 pounds, without the carriage, and can be worked by two men. It was found, however, at Vienna, in December, 1869, that to obtain the most rapid firing, or 481 balls per minute, five men were necessary to work the piece.

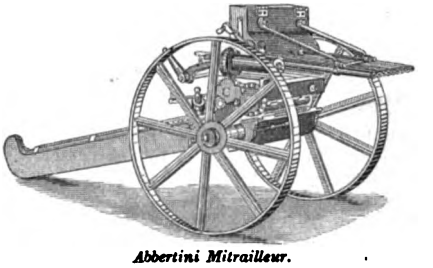
The front carriage contains from 48 to 56 boxes for loading, and the two caissons hold 16 breech-plates furnished with cartridges. The mitrailleur is, therefore, provided with 2,368 cartridges; and a battery of 8 mitrailleurs can hurl on an attacking column 3,848 effective projectiles per minute.

Another form of battery-gun employed by the French in the war with Germany consists of a series of barrels arranged side by side, the muzzles slightly diverging, and loaded at the breech by means of a rectangular breech-block containing two rows of chambers, one above the other. The cartridges are inserted into the upper row of chambers; the breech-block, which turns on an axis, is partially revolved, bringing the loaded chambers in line with the barrels, and the machine is fired, while at the same time the empty row of chambers is loaded; and these operations are repeated continuously. The machine was intended principally for defending the flanks of a column or line, or the angles of a square. It has no carriage, but is mounted upon a light frame of iron, with a pair of hinged legs in front and another in rear, which are locked in position for firing by a hinged brace, and which serve as handles for transporting it from place to place, two men performing this operation.

The Billinghurst and Requa battery, an American invention, consisting of 24 rifle-barrels arranged on an axle, and capable of parallel or diverging fire, was in use in the United States service in 1861.

The Abbertini, one of the forms of this weapon in use in Europe, has ten barrels similarly arranged; the working of the machine being performed by a crank which, through intermediate devices, conveys the cartridges to the barrels from the box-like magazine at the rear of the barrels upon the mounted frame or carriage. The barrels, after each discharge, are

Fig. 3184.



Abbertini Mitrailleur.

cleaned by special appliances; the entire number of barrels can be discharged from eighteen to twenty times a minute.

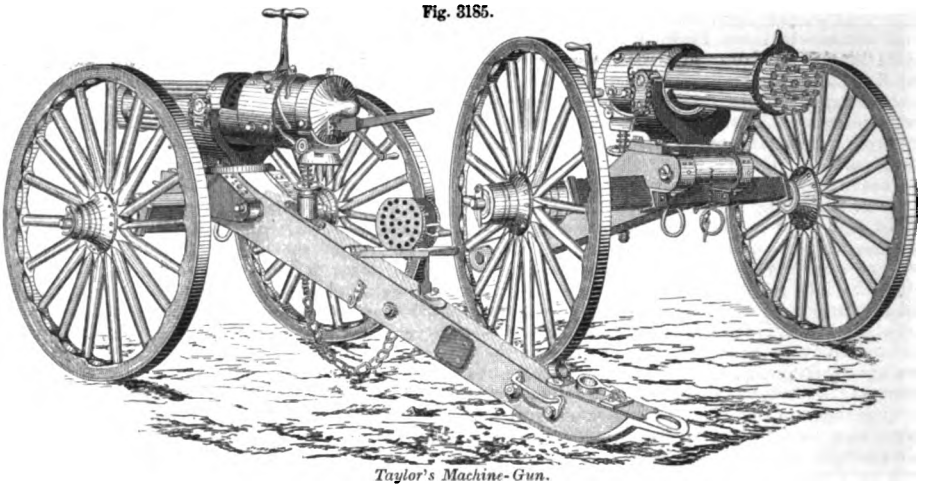
Hotchkiss's mitrailleur is a bundle of rifled cannon, throwing explosive shells weighing 2¾ ounces at the rate of 60 in 48 seconds. It is mounted and rotated like the Gatling gun, but the loading and firing apparatus differ from the latter. It has been tried experimentally in France and Italy.

Taylor's machine-gun is shown at Fig. 3185.

The charging-blocks, one of which is shown on the shelf on the trail of the gun, are filled with cartridges automatically from a magazine carried in the caisson, the magazine having chambers corresponding with those in the charging-block, and containing springs to press the cartridges forward. The rear view shows the gun open to receive the charge. The handle, seen in a vertical position, is attached rigidly to a sleeve, which has a concentric reciprocating movement of about 90°, and imparts a longitudinal movement to the breech-block and cascabel by means of studs projecting from the interior of the sleeve into spiral grooves in the sliding breech. The charge-block being inserted, the handle is drawn down into horizontal position. The rotation thus imparted to the sleeve closes the breech-chamber, slides the breech forward, pressing and locking the block firmly against the rear of the barrels, and, by means of plungers projecting from the front of the breech, forcing the cartridges partially through the block and into the barrels. The front view shows the arm with its breech closed in readiness for firing. The discharge may be effected simultaneously in all of the barrels by depressing the longitudinal lever which projects backward from the breech, and carries a pawl adapted to catch and suddenly release a sliding hammer concealed within the cascabel. The hammer is then driven forward by springs, striking all the firing-pins at once. The barrels can be discharged in succession by means of the crank shown at the side of the breech. This crank rotates a tappet or cam-wheel arranged to retract and release all the firing-pins in succession. The barrels are arranged

Digitized by Google

Fig. 3185.



Taylor's Machine-Gun.

in concentric circles at back, but diverge slightly forward so as to spread the fire in a horizontal plane.

The empty cartridge-shells are held by the charge-block and withdrawn with it.

Mit'ten. A hand covering, with one cell for the thumb and another which contains all the fingers.

It is a common and evident plan with clumsy manufacturers or material, or for the warmth of association of the fingers, to give the latter a common compartment and a special pocket for the thumb. Abbé Huc found the Tartarian gloves thus made. As a Frenchman, he was surprised; but these fellows had not been battling with winds fresh from Siberia for so long to no purpose.

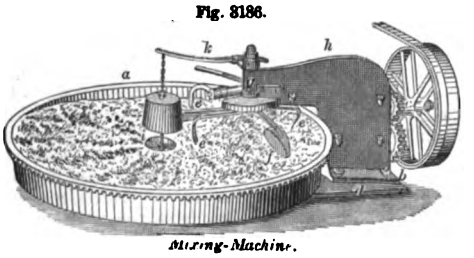
Mixed Fab'rics. Those in which two or more fibers are combined. The varieties are numerous; such as *tweeds*, *poplins*, *cassinets*, etc.

Mix'ing. 1. (*Cloth.*) Uniting wool of different colors for *mixed cloth*, called *medleys*.

2. Intimately compounding ingredients by stirring together, or passing together through sieves.

Mix'ing-ma-chine'. Poole's machine for mixing chemicals, fertilizers, etc., consists of a pan *a*, the upper edge of which is flanged, constituting a circular toothed rack, engaged by a gear-wheel on

Fig. 3186.



Mixing-Machine.

the same shaft with the wheel *b*, and turned by a wheel *c* on the driving-pulley shaft. A circular projection on the bottom of the pan fits a groove on the base-plate *d*, serving to steady the pan during its rotation; this may contain a lubricant. The stirrers or rubbers *e e* and scraper *f* are attached to an upright shaft, turned within the sleeve *g* on the arm *h* by bevel gears on it and on the pulley shaft. By this means they are constantly rotated during the revolution of the pan. When a charge of material is thus thoroughly mixed, the plug *i* is removed by lifting the lever *k*, when the material, guided by the scraper, passes through the central aperture into a discharge-pipe, or a vessel prepared to receive it.

Mix'ing-sieve. One by which ingredients are intimately combined by sifting together.

Mix'zen. (*Nautical.*) The aftermost mast in a three-masted ship, or in those two-masted ships in which the forward mast is the larger; such as the *ketch* and *yawl*.

The *main* is always the larger mast. When the larger mast in a two-masted vessel is forward, the one abaft is the *mizzen;* when the larger mast is abaft, the one nearer the bows is the *fore*-mast.

The word *mizzen* indicates the relation of many parts, as *mizzen-top*, *mizzen-shrouds*, *mizzen-rigging*, etc.

The *bonaventure mizzen* is a second or additional mizzen-mast employed in some ships with four masts.

Moat. (*Fortification.*) A ditch around a rampart.

Moc'ca-sin. A deer-skin sandal, the sole and upper of which are formed of one piece of leather.

The Indian process is as follows: The skin is stretched and dried. The brains are dried in the sun. The skins are soaked, hair removed by a knife, placed with the brains in a pot and heated to about 100°. The skins are taken out, wrung, stretched with lines and pegs, and persistently rubbed with a hard stone to soften them. Among some tribes the leather is softened by mastication. The squaws of course do the chewing. See PAC.

Mock Gold. A yellow alloy. Factitious gold.

	Copper.	Platinum.	Magnesia.	Zinc.	Tin.	Borax.	Sal-ammonia.	Saltpeter.	Lime.	Tartar.	Putty.

We read of one copper alloy in Strabo, called by him a mock silver (*Pseud argyrum*). It is not clear whether the stone which was added to the copper was an ore of nickel or some other white metal. He calls the alloy *oreichalcum*. Brass and bronze were well known to him, and this alloy was of a white color.

Mod'el. 1. A pattern, usually on a diminutive scale, of a work which has been or is to be done.

Working-models are diminutive machines, with all the parts capable of performing work on a scale proportioned to their size.

The best and largest collection of mechanical models in any country or time is that in the United States Patent Office, where, since 1836, have been deposited the models accompanying about 200,000 applications for patents, excepting in that small proportion of the inventions consisting of processes and compounds in which no model is required. The model saloon occupies the whole upper floor, a circuit of 2,000 feet, the cases being arranged on both sides of the four long halls encircling the building. The cases are in double tiers with galleries.

Ingenious mechanics in all ages of the world have devoted much time and skill to the manufacture of minute mechanical devices. "In the twentieth year of Queen Elizabeth, a blacksmith named Mark Scaliot made a lock, consisting of eleven pieces of iron, steel, and brass, all of which, together with a key to it, weighed but one grain of gold. He also made a chain of gold, consisting of forty-three links, and having fastened this to the before-mentioned lock and key, he put the chain about the neck of a flea, which drew them all with ease. All these together, lock and key, chain and flea, weighed only one grain and a half.

"Oswaldus Norhingerus, who was more famous even than Scaliot for his minute contrivances, is said to have made sixteen hundred dishes of turned ivory, all perfect and complete in every part, yet so small, thin, and slender that all of them were included at once in a cup turned out of a peppercorn of the common size. Johannes Shad of Mitelbranch carried this wonderful work with him to Rome, and showed it to Pope Paul V., who saw and counted them all by the help of a pair of spectacles. They were so little as to be almost invisible to the eye.

"Johannes Ferrarius, a Jesuit, had in his possession cannons of wood, with their carriages, wheels, and all other military furniture, all of which were also contained in a peppercorn of the ordinary size.

"An artist named Claudius Gallus made for Hippolytus d'Este, Cardinal of Ferrara, representations of sundry birds sitting on the tops of trees, which, by hydraulic art and secret conveyance of water through the trunks and branches of the trees, were made to sing and clap their wings; but at the sudden appearance of an owl out of a bush of the same artifice, they immediately became all mute and silent." — *World of Wonder*.

Boverick, the French artificer, made a chain of two hundred links, with its padlock and key, all weighing together less than the third part of a grain. He was also the maker of a landeau, which opened and shut by springs. This miniature equipage, with six horses attached to it, a coachman seated on the box, with a dog between his legs, four inside and four outside passengers, a postilion riding one of the four horses, was drawn with all the ease and safety imaginable by a flea.

A writer in the "Gentleman's Magazine" gives the following account of a visit to the model-making workshop of Thomas Smith, on the Surry side of the river Thames, near Lambeth Palace, London.

"Beginning with the larger of his productions, the first object to which he directs our attention is a small steam-pumping engine for working a table fountain. All the adjuncts that pertain to a great pumping-engine are to be found in this diminutive model. There was even the gage glass on the front of the boiler, as slender as a good-sized needle, and fitted with taps at each end, in the nozzles of which a pin could hardly be inserted. The whole thing worked to perfection, without rattling or any escape of steam from the engine or water from the pumps, and will throw a small jet of water in a distant part of the room to a hight of twelve feet.

"At the time of our visit a number of diminutive garden-pumps, small enough to be carried in the waistcoat-pocket, are scattered over the work-benches in various stages of completion. These are for the use of agents and commercial travelers trading with such articles. But the above-described curiosities are huge compared with those next set before us. We are introduced to a model of the famous 'Great Britain,' made to a scale of $\frac{1}{10}$ of an inch to the foot, so that the length of the model is about 8 inches, and the breadth about $1\frac{1}{4}$ inch. It is full-rigged, with six masts and their accompanying spars, and all the hatchways and deck fittings. The deck of this tiny vessel is lifted off and a magnifier is handed to us; this resolves a little heap of metal scraps into an accurate model of the original engines with which the 'Great Britain' was fitted. So small is this model that it stands upon less space than the area of a shilling. An annular trough of water is produced, and the ship is launched into the watery circuit. A tap is turned, and compressed air rushes through a tube, and off goes the tiny ship to circumnavigate its little sea. The total weight of the boat, with deck and rigging, engines, boiler, and all entire, is less than a troy ounce! The actual weight of the working part of the engines — that is, all excepting the boiler — is just that of a sovereign."

One of the tiniest working models in the world is now in the possession of John Penn (of Greenwich), the eminent maker of the great engines of which it is the reduced counterpart. It will stand on an English silver 3 *d.* piece; it really covers less space, for its base-plate measures only $\frac{3}{8}$ of an inch by about $\frac{1}{2}$. The engines are of the trunk form introduced by Penn; the cylinders measure $\frac{1}{8}$ of an inch in diameter, and the trunk $\frac{1}{20}$. The length of stroke is $\frac{3}{40}$ of an inch. They are fitted with reversing gear, and are generally similar in design to the great machines with which ships of the "Warrior" class are equipped. From the extreme smallness of this model a few minutiæ — such, for instance, as

Digitized by Google

the air-pumps — have necessarily been omitted; so small are some of the parts, that they require a powerful magnifying-glass to see their form. The screws which hold the members together are only $\frac{1}{70}$ of an inch in diameter, and these are all duly furnished with hexagonal nuts, which can be loosened and tightened by a Liliputian spanner. The whole weight of the model is less than a threepenny-piece.

A steam-pump, consisting of a steam and water cylinder, made by Charles Fichtel of Philadelphia, in 1860, was auxiliary to a model of a steam fire-engine. The steam-cylinder was $\frac{1}{8}$ of an inch in diameter, and the whole affair would go into a common thimble.

2. (*Plastic Art.*) The invention of the art of modeling in clay is attributed to Dibutades the Corinthian, about 985 B. C. His daughter traced the profile of her lover, by his shadow on the wall; and her father filled up the outline with clay, which he afterwards baked. Had Pliny known more of Egypt and Phœnicia he might have made a better statement. Pots and lamps had been made in rude resemblance of faces and figures for unknown ages past. Etruria, from which Rome received her agriculture, fine arts, armor, metal-working, astronomy, navigation, measurements, coins, weights, furniture, dress, habits, and medicines, was also her mistress in the ceramic art. Geodetical models, in which the contour of the earth is shown in relief, are among the most interesting of all geographical representations. The mountains of Switzerland were modeled in miniature, by General Pfiffer. In modeling a tract of country, it is usual, as in plotting a profile of a route, to exaggerate the hights to make them more observable. With such vast precipices and eminences as Switzerland affords, the necessity for vertical exaggeration is not so great; but it is apparent that in a modeled map of a country 200 miles square, having no elevation exceeding 1,760 feet, a rise of $\frac{1}{8}$ of an inch on a surface 16 feet square (one inch to the mile) would not be readily seen. The insignificance of the elevations on the earth's crust, compared with the area of the surface, is not generally appreciated, and it is common in plotting profiles of routes as in modeling the superficies, to give the rises and elevations ten times their actual proportion. This is to render them more visible. The largest attempt at geographical modeling was by Mr. Wyld, in his globe erected in Leicester Square, London, 1851 – 53. (See GLOBE.) The *interior* surface (for convenience of general view) was modeled to represent the chains of mountains, table-lands, river valleys and depressions. It was executed in sections, and castings therefrom were afterward associated on the interior of a vast shell, and painted.

Models of towns and ancient buildings in wood, plaster, and cork have excited much attention and interest, and are common in museums.

Mod'el-ing-board. A board used in loam-molding to give shape to the mold.

Mod'el-ing-plane. A short plane used in planing rounding surfaces. It has a length of from 1 to 5 inches, a width of from $\frac{1}{4}$ to 2 inches. The irons are from $\frac{3}{8}$ to $1\frac{1}{2}$ inches wide.

Mod'er-a'tor. (*Optics.*) A device, known as Rainey's, consisting of an opal glass or ground glass to moderate and diffuse the light passing from a lamp to an object on the stand of the microscope.

Mo-dil'lion. (*Architecture.*) *a.* An ornamental console beneath the corona in some orders.

b. One of the large flowers in a soffit or coved ceiling.

Mod'ule. 1. A measure of proportion. See MODULUS.

2. The lower diameter of the shaft of a column.

Mod'u-lus. In mechanics, a coefficient of some specified force or property.

"*Modulus of a machine*, a formula expressing the work which a given machine can perform under the conditions involved in its construction. The relation between the work done on a machine by the moving power and that yielded at the working points, either constantly, if its motion be uniform, or in the interval of time which it occupies in passing from any given velocity to the same velocity again, if its motion be variable. Called also the *efficiency* of the machine.

"*Modulus of elasticity*, the measure of the elastic force of any substance, expressed by the ratio of a pressure on a given unit of the substance to the accompanying compression. Or an expression of the force which would be necessary to elongate a prismatic body of a transverse section equal to a given unit, or to compress it within the limits of its elasticity.

"*Modulus of rupture*, the measure of the force necessary to break a given substance." — RANKINE.

Mo'el-lon. Rubble stone filled in between the facing walls of a structure, or between the spandrels of a bridge. It consists of clean, broken stone, and where it holds an important position, as in the last-mentioned case, it is laid in mortar, and by hardening becomes equal to a solid mass of stone.

Mo'hair. (*Fabric.*) From a Hindoo word. *a.* A fabric made from the fine, white, silky hair of the Angora goat and allied species. Sometimes called *camlet*. The hair is said to be produced in perfect quality in no place excepting Angora in Asia Minor, and has long been a valuable article of export from that place.

b. A wool and cotton goods made in imitation of the above, in mixed colors or plain.

Moiles. The metallic oxide adhering to the glass which is knocked from the end of the blow-pipe.

Moi'neau. (*Fort.*) A small, flat bastion raised in front of an intended fortification, to defend it against attacks by small-arms.

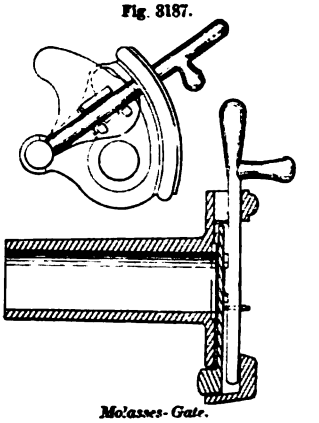
Moire. Watered or clouded silk. The thick silk goods is damped, folded in a peculiar manner, and subjected to great pressure, say, from 60 to 100 tons. "Green watered moyre" is mentioned by Pepys in his Diary, 1660.

Moire An-tique'. (*Fabric.*) A heavy, watered silk.

Moire Met'al-lique'. Tin plate which has been acted on by an acid, so as to display by reflected light the crystalline texture of the tin.

A surface of tinned iron is rinsed in an alkali water, dried, warmed, washed in a solution of nitric and hydrochloric acid, dipped in water, washed, and dried. It is then covered with colored varnish. A film of peculiar crystallization is produced in larger or smaller patterns, according to the mode of applying the acid.

Fig. 3187.



Molasses-Gate.

Mo-las'ses-gate. A faucet with a sliding lip at the discharge end, to cut off the flow positively and prevent drip.

Mold. The ma-

Digitized by Google

trix in which an object is cast. A templet or shaper by which an object is tested for shape or marked to a shape.

1. (*Founding.*) Molds for casting are of several kinds: —

Open molds, into which the metal is poured, the upper surface of the fluid metal assuming the horizontal position. Such are ingots and some other objects.

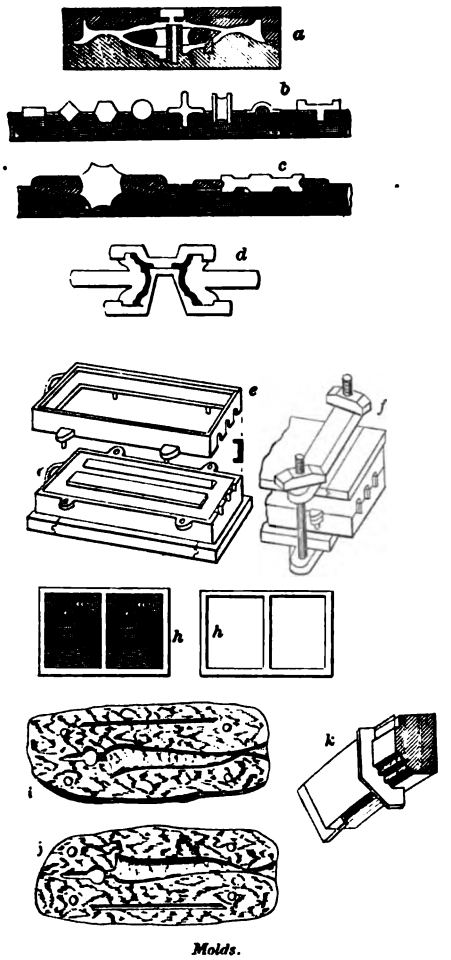
Close molds of metal or plaster of Paris, with ingates by which the molten metal enters. Such are the molds for inkstands, cannon-balls, bullets, type, and various other articles made of lead, tin, zinc, and their alloys which fuse at a moderate heat.

Close molds of sand, in which articles of iron, brass, bronze, etc., are cast. This is the ordinary foundry work, and includes machinery, stoves, ordnance, and the multitude of articles of domestic and agricultural hardware.

Loam-work casting, in which the mold is built up, instead of being rammed around a pattern, subsequently withdrawn. This is used in casting cylinders, tanks, bells, or ordnance of very large size.

For specific index see FOUNDING.

Fig. 3188.



Molds.

a is a mold of a car-wheel in sand, shown in section.

b is a section showing several small articles partially imbedded in the drag or lower portion of the mold.

c is a view of an article with undercut portions requiring a peculiar treatment by core pieces, which are taken away to remove the pattern, and laid back again before closing the mold.

d is a metallic mold for britannia and pewter ware.

e is a flask, the drag and cope being separated to show the parts. See FLASK.

f shows a portion of the same, with the parts of the flask fastened by a clamp.

i j is an ancient mold for bronze knives, found in the lake of Brienne, and belonging to a period of several thousand years past. It is a gray sandstone of great porosity, and has corresponding holes for the reception of wooden pegs to keep the parts of the mold in place. It is about 12 inches long.

Roman coins were (sometimes) cast in molds, hollowed out in a kind of stone. Molds were also used in making pottery, pastry, cheese, bricks, pisé walls, shoemaker's lasts.

The invention of molds for the casting of wax figures is ascribed to Lysistratus, about 328 B. C.

g h are molds for paper-making.

k is a plasterer's mold for shaping cornice.

The fusibility of metals and alloys is the basis of the founder's art, and furnishes one means by which they are given the varied forms which fit them for application in the arts.

The softer metals and alloys, such as lead, pewter, type-metal, britannia-metal, and even zinc, are usually cast into metallic molds which are used over and over again; but in a more restricted sense molding embraces the formation of molds in sand and loam only, and the filling of such with metals and alloys fusing above a red heat, as cast-iron, brass, gun-metal, bell-metal, etc. In all these cases the mold can be used but once; after pouring and cooling it is broken up to get out the casting, part of its sand only being used again.

The trade of the iron-molder is distinct from that of the brass-molder (who also deals with gun and bell metal), but the methods employed are so nearly identical, that a distinction in describing the several operations is not necessary.

a. Molds are made in *green-sand*, *dry-sand*, and *loam*. For the first two a *pattern* is required; in the latter it is generally dispensed with.

Patterns are mostly made of wood, although brass and iron are also common, especially when large numbers are required. A pattern always represents the appearance and dimensions of the casting as far as its external surface is concerned. This is also frequently true of its internal surface, but not invariably so, dry-sand *cores* made apart from the pattern being often introduced to form the cavities and internal spaces required. (See CORE.) Patterns are sometimes made in two or more pieces fastened together by pins or dowels, the object being to facilitate their removal from the sand.

The term *green-sand* molding is employed to express the fact that the sand is used pretty much in its *green* or natural state, and is not subjected to any drying or baking process before casting; it is the method followed for the great mass of castings, both iron and brass. The sand for this purpose is kept damp, sufficiently so to ball into a compact mass when squeezed in the hand, but it must not be wet, or approach that condition.

The brass-molder keeps his sand in a molding

Digitized by Google

trough or bin, over which he works; small castings forming the bulk of his work: but in an iron foundry the whole floor to a considerable depth is formed of *old-sand*, and on this the surplus quantity for use is gathered together in large mounds.

In working from a pattern in green-sand the object in view is to produce in the finely packed sand a cavity identical in form with that of the pattern; the same being afterwards filled with molten metal and left to cool. To accomplish this the workman is provided with a large assortment of *flasks*, or *molding-boxes* of the most various dimensions; they are designed to hold the sand used in making the molds. Small flasks are simply rectangular frames resembling ordinary boxes, but without either top or bottom; each part being 3 to 6 inches high. They are connected together generally in pairs (often three or more), by *steady-pins*, which allow of their separation when full of sand, and their restoration to exactly the same relative position afterward. Large flasks are provided with cross-bars at suitable distances to prevent the sand, which has been rammed into them, from falling out of its own weight, or rising from the upward pressure of the fluid metal.

In this country, flasks are frequently made of wood; only in the larger foundries is iron used to any extent; but in Europe, and especially in England, wooden boxes are rarely seen. Even where iron is always used, wooden cross-bars are frequently employed with advantage, as they admit of being readily cut away to suit patterns of unusual form. The lower side, or *drag*, has generally only flat bars connecting its lower edges, so that it can be lifted, but not turned over after it is once full. See FLASK.

The following description will serve to illustrate the principles which govern and guide the molder working in green-sand. One flask being laid with its lugs uppermost is filled and rammed up with old-sand, and stricken off level with the joint of the flask: this is called a *false-part*. If now the object to be molded has an elliptical form, as shown in section *b c*, Fig. 3188, the sand in the false-part is cut away roughly, so as to imbed one half of the pattern. Some dry *parting-sand* is next scattered over the surface. This adheres to the damp sand, and prevents any union between such a surface and any other sand subsequently rammed upon it. After the parting-sand is blown off the exposed part of the pattern, the other side or *drag* is put on, its steady-pins entering the holes in the lugs of the false-part easily, but without shake. Newly prepared sand, *facing-sand*, is next sieved over the pattern in sufficient quantity to cover it completely; the box is filled with old-sand from the floor of the shop, and is carefully rammed up and stricken off. After provision is made for the escape of gases from the sand by prodding it all over with a sharp-pointed steel wire, known as a *vent-wire*, the two flasks are held together and turned over on a bed prepared for the drag upon the floor, or on a flat board if the boxes are small, and the false-part, having done its work, is lifted off and emptied. An exact *parting* is now made with the trowel along the median line, if the casting be symmetrical, the damp facing-sand being added to or cut away sharply up to the pattern as occasion may require. The *parting-line* is, as a general rule, that line upon the pattern, as it lies in the sand, above and below which the sides of the pattern run inward from the perpendicular. This is frequently an undulating line, but the parting surface always runs from it in all directions to the horizontal edge of the box. Parting-sand is now strewn over the whole, and the surplus blown off. The upper flask or *cope* being replaced, a short cylindrical *runner-stick* is thrust into the sand of the lower part at a convenient distance from the pattern; facing-sand is sieved on, the box filled up with old-sand, rammed up, and stricken off as before. The vent-wire is then used as with the drag, the runner-stick withdrawn, and the opening left, through which the metal has ultimately to pass to the mold, is given a bell-mouthed shape.

Having arrived at this stage of the work, the molder, either alone if the box be small, or with the help of other workmen or the crane itself if it be large, lifts the cope steadily upward, leaving the pattern in the sand of the drag. The cope is then usually turned over on wooden blocks for repairs and dressing. The pattern is now to be *drawn* from the sand. This is done with the help of spikes or screwed rods, temporarily attached to it; with one or more of these it is lifted, being made to vibrate the while by rapid tapping with a piece of wood or iron, for the purpose of causing it to leave the sand readily. The molder has now to repair with suitable tools any broken parts of the sand forming the mold, then to cut the *runners* or channels from the opening left by the *gate-stick* to the mold, along which the fluid metal finds its way; and lastly to dust finely powdered charcoal from a linen bag over the facing-sand surface, if the mold is for iron, and mill-dust or similar farinaceous substance, if for brass. Charcoal, when this is used, is slicked down with the trowel and slicker as far as possible, so as to bring it into intimate contact with the damp sand. The excess of dust in every case is blown off with the bellows. When the top part is *c'osed*, it occupies exactly the position it did before; the space then filled by the pattern being now vacant and in connection with the gate, the hot metal can therefore make its way so as to fill such space, the form of which it will be found to have taken when cold.

The foregoing may be regarded as typical of all solid work in green-sand, the imaginary case cited being almost the simplest possible. When hollow work is required, especially if the cavities are long or tortuous, dry-sand or loam *cores* (which see) are employed to form such openings. These are made either by pressing damp sand of suitable composition into a sort of wooden mold, known as a *core-box* (which see), from which it is removed and dried by artificial heat, or by attaining the same end by the use of plastic loam on a perforated barrel or *core-plate*. When such a core is perfectly dry, having received a thin coat of a mixture of clay, water, and charcoal-dust, called *black-wash*, it is placed in position in the mold. This is determined, and the core is held in its place by making it longer than the hole in the casting, and letting the added parts rest in suitable cavities in the sand, made by projections on the pattern known as *prints*. An ordinary water-pipe is a good illustration of this class of work. The pattern for such a casting is solid, and has cylindrical projections of the inside diameter of the pipe at its ends. The long core, through which runs a perforated barrel for the escape of gas, rests upon that part of the mold which is made by the prints, and completely fills those cavities; but it leaves a space all round which exactly represents the pipe, and which is finally filled by melted metal.

b. Dry-sand molding may be regarded as identical in all essential points with that in green-sand, save that the mold when finished is thoroughly and strongly dried by artificial heat. By this treatment the sand especially prepared for the work is baked to a hard compact mass. Dry-sand molding is chiefly used for heavy castings, where great solidity and

Digitized by Google

strength are required. The drying is done in a heated room called the *stove*.

c. Loam-molding is entirely distinct from the preceding methods of working. *Loam*, as prepared for this purpose, is essentially to be regarded as a mixture of sand and clay, the latter in quantity sufficient to give a plastic character to the mixture when tempered with water to the consistence of mortar or plaster. This material is much used for the construction of large molds and cores, and, as has been previously stated, it obviates the necessity for patterns — generally very costly ones — and core-boxes. Loam cores are *struck* up, usually upon a hollow perforated spindle covered with a layer of hay-rope. The spindle — often consisting of common gas-pipe — is made to run in notched trestles upon which a board (*loam-board*) rests parallel to the axis of the spindle. The loam is heaped upon this board, while the spindle at a proper distance is made to revolve slowly before it by a simple winch-handle. After it is thoroughly dried in the *drying-stove*, it is turned to the exact size, black-washed, and dried again, when it is ready for use.

Loam-molding applied to large castings, such as cylinders, pans, or large water-pipes, is really conducted on principles quite analogous to the above. As a typical instance, the molding of a large sugar or soap boiler's pan is here described. Such a vessel is cast mouth downward. A heavy, flat, cast-iron plate (*loam-plate*) *b*, in the form of a ring, is laid upon the low carriage or truck which runs in and out of the drying-stove. The outside and inside diameters of this flat ring are respectively greater and less than that of the rim of the pan, and it is also provided with four heavy projections by which to move it and the mold upon it, by means of the crane, from the *stove-truck* to the pit in the floor where the casting is made. In the center of this ring rises a perpendicular spindle running in a long bearing provided for it in the carriage, and carrying a movable arm from its upper end. A hollow templet of wood of the exact sweep of the inside of the pan is now clamped to the cross-arm of the spindle, and the latter is lowered so as to bring one end of the templet down to the plate, and there it is fixed. In revolving through a complete circle, the edge of the templet will now describe a figure representing the inside surface of the pan. A rough dome of common brick set in loam is now built upon the ring, keeping it two or three inches clear of the templet, and leaving an opening at top large enough for the spindle to turn in. Loam is then applied to the dome in two or three coats, and it is finally *struck-up*, with the help of the revolving templet, to an exact form. This structure is dried, and then black-washed, and is known in loam-molding as the *nowel*. The templet used hitherto is now replaced by another which gives the form of the outside of the pan. With its help the *thickness* is struck-up upon the nowel, in loam which contains a good deal of clay. It will be seen that this application represents the thickness of metal required for the pan. When dry, it is likewise black-washed, and dried again; the last application in both cases being made to secure a parting. A second cast-iron ring, also provided with heavy ears or lugs, is lowered down till it rests upon that part of the first loam-plate which extends beyond the *thickness*, last applied. A coating of wet loam is then put on with the hand to the surface of the *thickness*, and a second dome of brick is built right against it. When all is dry, the position of the second ring is marked, or secured with pins. The crane is then made fast to it, and the *cope* is lifted off. In all probability the thickness-loam in doing this will break to pieces; if it does not, it is gently knocked away, and both surfaces, that of the *nowel* and *cope*, are repaired and dressed, and finally black-washed. Before this is done the spindle is lifted out, and the opening in the nowel carefully closed; that in the cope usually plays the part of ingate. When both parts of the mold are united, a space now remains corresponding to the *thickness* removed, ready to receive metal. By means of the crane, made fast to the lower ring, the whole is deposited in a pit, and old-sand rammed about it, so as to hold the cope down, and increase its power of resisting the lateral pressure of the metal, which is very great. Adequate provision is also made for the easy escape to the surface of the gases generated by the hot metal, especially those forced inwards through the dried loam and brick-work of the nowel. The formation of the ingate is also carefully attended to.

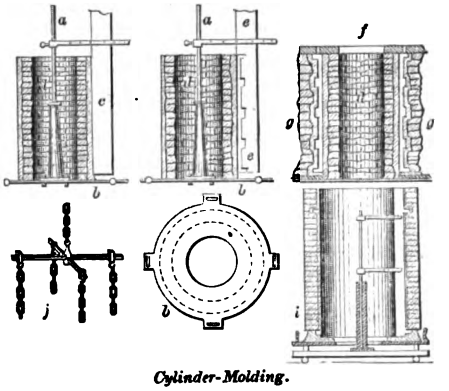
In smaller foundries, and sometimes in those with very perfect appointments, loam-molds are made so large as to render it necessary to dry them *in situ*. In such cases slow-burning fires are made under them in the open shop, and the evaporation of the water is accomplished as best it may.

The *pouring* of brass and iron castings is accomplished from crucibles or ladles respectively. In large iron works several ladles, each containing from two to four hundred weight of metal, are often used simultaneously; for still larger masses, crane ladles holding six or eight tons are employed, and when such are insufficient the mold is filled by leader channels direct from the furnace.

Fig. 3189 shows several stages of the process of cylinder molding by the loam-work process.

A vertical axis *a* is mounted upon a pedestal in the center of the plate *b*, as shown in the figure,

Fig. 3189.



Cylinder-Molding.

or it may be attached to the building or a beam of the roof. A radial arm projects from this axis and carries a *templet c*, which is maintained in rigidly perpendicular position by firm attachment to the radial arm, which rotates with or around the central axis, so that the edge of the templet describes a cylinder in its rotation.

d shows an interior cylinder built up of bricks and plastered over with soft loam, scraped into cylindrical form by the *templet c*, which revolves on its axis. When the surface is made smooth and fair, this part of the mold is dried; it is then brushed over with black-wash and again dried. The charcoal-dust of the black-wash acts as a parting, to prevent the succeeding layers of the loam-mold from adhering to the first.

Digitized by Google

The cylinder thus made by templet *c c* is the mold for the inner surface of the future cylinder. It is the *core* or *nowel*.

The next figure represents another templet *e e*, attached to the same axis, having an edge conformable in its outline to the *outside* surface of the future steam-cylinder. The distance of the edge of the templet *e e* from the blacked surface of the *nowel* is equal to the thickness required for the steam-cylinder. Loam is placed on the nowel, and smoothed to shape by the revolving templet *e*, which is then dismounted and the spindle removed. The thickness of this loam is represented white in the figure. This loam then receives a coat of black-wash, which prevents it from adhering to the coat to be placed outside of it.

f represents the mold in a farther stage. A wall of bricks *g g* is built around the previous construction, loam being carefully worked against the material which represents the thickness of the future cylinder. The new work or *cope* is now thoroughly dried, and afterward lifted off by means of a crane and a cross-beam with four chains, as shown at *j*. This part of the process usually drags off the thickness of loam which represents the cylinder, and this commonly breaks out during the removal. What remains is carefully picked out of the cope, as it has now served its purpose, and the interval existing between the *nowel* and *cope*, when the parts are restored to their proper relative positions, is to be filled with molten metal to form a cylinder.

When the cylinder requires *ports* at the ends, or the short tube with flanges for attaching the steam-pipes, models of the tube are worked into the cope, and are afterwards withdrawn; the cores are made in core-boxes, and are partly supported by the outward extremity and partly upon *grains*, or two little plates of sheet-iron connected by a central wire, the whole being equal to the thickness of the metal at that point. When steam passages are wanted, either along the side or around the cylinder, they are worked up in clay upon the thickness and duly covered in by the cope; their cores are supported, partly by their loose ends and partly by *grains*, which become entirely surrounded by and fixed in the metal when it is poured.

The mold is now put together in a pit sunk in the floor of the foundry, and the top covered in with a loam-cake, perforated with holes for the entrance of the metal and the escape of the air. The *core* is sustained by iron bars, and the *cope* by iron rings, so as to withstand the pressure of the column of metal.

With some large cylinders, such as those of the Cornish pumping-engines, 80 to 100 inches bore and 12 to 14 in length, also the cylinders of the large blowing-engines of blast-furnaces, the *nowel* and *cope* are made separately, as at *i*. The *cope* is built up and turned inside with a radius-bar; the *core* is erected on a plate on the floor and turned on the outside to a gage; when dried, it is lowered into the cope by a crane.

A modification of the plan for loam-work casting of cylinders and similar large hollow articles, is found in making the cope divisible by a vertical joint, so as to separate laterally into two semi-cylindrical portions which rest upon semi-annular plates, so as to slip back while the thickness representing the metal is removed.

Large water-pipes are cast upon cores, which are made of a layer of loam upon a hay-band wound upon a perforated pipe, the pipe being supported on a bearing, and the loam turned off to a smooth surface, which is dried and black-washed. The *thickness* is laid on and black-washed, and this substitute for a pattern is molded in sand. The core with its envelope is withdrawn, and the *thickness* removed; the core is supported in the mold by the *prints* at the ends and by *grains* with long wires.

Pipes are also made from wooden patterns cut in halves through the axis. The *drag* and *cope* respectively receive the impression of one half, and when the pattern is removed the mold is ready for the core and the making of the ingate.

The molds for crooked pipes and branches are frequently made in halves upon a flat iron plate. An iron bar or templet of the curve required is laid down, and a semicircular piece of wood, called a *strickle*, is used for working and smoothing the half-core; next, a larger *strickle* is used for laying on the thickness; the two halves are then fixed together by wires and molded from in the sand-flask; the thickness is now stripped off the core, which is fixed in the mold by its *prints*, and, if needful, is supported also upon *grains*.

The infinite variety of forms which the molder is daily called upon to reproduce, as well as the constantly varying conditions and materials with which he has to deal, renders his trade an arduous one, requiring much judgment, experience, and forethought. For this reason, also, it is not possible to explain or even enumerate in the space at my disposal the endless modifications of the above typical cases which are constantly occurring. As the best substitute for such exhaustive treatment, however, a list of materials and technicalities used in molding is appended, with explanations designed to elucidate this most important, interesting, and many-sided art.

d. (*Plaster-casting.*) *Waste*-molds are those which admit of but a single cast, from which they are subsequently removed by breaking. *Safe*-molds are those made in a number of pieces, which are so arranged as to be withdrawn separately from the casting and admit of being put together again for a repetition of the process. We are indebted for the invention to the Italians and French of the fifteenth, sixteenth, and seventeenth centuries. With some elaborate subjects the number of pieces required has exceeded 700.

See also STATUARY CASTING.

e. Soft and perishable objects may be so molded as to produce a single casting by one of the several following methods, which are adapted to procuring castings of small animals, insects, flowers, feathers, ferns, sea-weed, wax-models, etc.

1. Support the object in the center of a small box by means of needles, one or two of which should be sufficiently large to form *ingates*. Some fine river-mud is dropped into the box, and shaken around so as to adhere to the object. When partially dry, a coarser grade of silt is thrown in, and successively coarse qualities until the box is filled. The needles and ingate wires are now withdrawn, the mold burnt to reduce the object to ashes, which are shaken and blown out, when the mold is ready for pouring the metal.

2. Another method is to take the object itself or a wax model, such as that of a flower, and suspend it in a box while plaster of Paris is carefully poured around it. The application of heat causes the object to burn or the plaster to absorb the wax, or, if the latter be in excess, it can be poured out. The strings by which the object was suspended are withdrawn, and the mold is ready for casting. The castings may be covered with gold or silver by the electrotype process.

This plan was adopted in casting the feather of the equestrian statue of George III. at Pall Mall, London, and specimens of ears of wheat, flashy flowers,

Digitized by Google

such as coxcombs, and other beautiful objects, have been exhibited.

Branson, of Sheffield, England, has pursued a somewhat analogous method in obtaining castings from ferns, algæ, etc. A slab of gutta-percha is softened by boiling water, laid on a smooth metallic plate, dusted over with fine bronze-powder, and the frond impressed thereon by a flat upper plate, imbedding the frond in the gum. When cooled, the leaf is withdrawn, and the mold is used to obtain a casting or an electrotype, from which impressions in ink are obtained by the copperplate process.

Auer's plan of *nature-printing* is to impress the frond into soft, polished sheet-lead, by passing between polished rollers. The impression is used for printing, or a copy in a harder material is obtained by the electrotype process.

Wallis's *autographs* were obtained by making drawings in a material which is salient upon the paper, so as to make an impression in the soft plate when the two are passed between the rollers. The plate is used as in Branson's and Auer's processes.

Molders' Terms.

(Referred to at greater length under their alphabetical heads.)

Air or *foul air*. The gases generated in casting, and driven through the sand.

Air-drain. A passage to conduct gases from molds deeply bedded in the floor of the molding-shop.

Air-gate. An opening at which displaced air escapes during pouring, and in which metal afterward rises.

Barm. Yeast used in the preparation of core-sand to render it adhesive.

Bellows. Used to blow loose sand or dirt out of the molds, or parting-sand from the pattern.

Blackening. Charcoal-dust applied to a mold to give smoothness to a casting.

Black-lead. Sometimes used for blacking molds or for mixing with sand.

Black-wash. A solution of clay and powdered charcoal applied to the surface of sand-molds, to give a clean skin to the casting; also used as a parting. See Sand.

Blow. The forcing of displaced air through the molten metal from insufficient vent.

Blown The condition of a casting containing cavities caused by inclosed air.

Bot. A pear-shaped piece of stiff clay used to stop the flow of metal from the tap-hole of the furnace.

Bot-stick. The rod provided with a long wooden handle at one end, and a small round disk at the other, to receive the clay, used for *botting-off* when the ladle is sufficiently full.

Box. A very common term signifying *flask;* a contraction of *molding-box*. See *Flask*, below.

Brick. Used largely in loam-molding.

Burned in. Union produced by flowing hot metal in quantity over cold.

Burned sand. Sand, the tenacity of whose clayey portion has been destroyed by the heat of the metal. See Sand.

Case. A *cope*.

Cast-gate. The *ingate* at which the metal is poured in.

Chaplet. A wrought-iron stud to hold a core in position in a mold. A *grain*.

Charcoal. Used in dust, as dry *blackening*, or in suspension with clay, as *black-wash* (which see).

Chill. A piece of iron in a mold to suddenly cool the metal flowing against it and render it hard.

Clay. Used according to quality, — fire-clay for walls and boshes of furnaces, commoner for bricks and for loam.

Clay-wash. Clay in solution for smearing the insides of molds and gaggers, to make the sand stick; for cementing the portions of cores; for strengthening loam and adding to charcoal to make *black-wash*.

Cleaner. A tool of thin steel or brass, from 6 to 18 inches in length. One extremity has a bent spatula blade; the other a short blade bent on the flat to a right angle. Used for smoothing the molded surfaces and removing loose sand.

Coal-dust. Powdered coal added in certain quantities to green-sand, according to the quality of the latter.

Coke-dust. The same in effect as coal-dust.

Cope. The flask which is uppermost at the time of casting. The *upper box* or *top-part*. The outside portion of the mold in *loam-work*. Also called the *case*.

Core. A mass of sand, molded and baked, and placed in a mold to form a cavity in a casting.

Core-bar. An iron bar to stiffen a core.

Core-barrel. A perforated iron tube to form a passageway for the gases passing off through the interior of a core.

Core-box. A mold in which a core is formed.

Core-pipe. A core-barrel.

Core-print. A portion of a core which rests in seats in the mold and supports the core in place

Core-sand. Coarse new sand with powdered loam.

Cotter. A key which locks the steady-pin of a flask.

Cow-hair. Used as a bond to increase the tenacity of loam.

Crane. The hoisting apparatus of a foundry to move heavy flasks, castings, etc. See Crane; Foundry-crane.

Deliver. A pattern is said to *deliver* well when it leaves the sand without breaking down the mold.

Drag. The lower box or bottom part of the flask.

Draw. The taper of a pattern which enables it to leave the sand without impairing the mold. To lift the pattern from the sand.

Drawback. A *false-core*.

Drop. The fall of sand from the top-part into the mold.

Dry-sand. That description of molding done with loam and sand in due proportion, the mold being oven-dried before casting. See Sand.

Drying-stove. A heated room for drying dry-sand molds or cores.

Face-dust. Powdered charcoal for iron castings, mill-dust or pease-meal for brass. It is dusted from a bag over the mold to improve the surface of the casting. Powdered soapstone, rottenstone, graphite, or chalk is sometimes used.

Facing-sand. New-sand used in immediate contact with the pattern, being sifted thereon and then backed up with old-sand and rammed.

False-core. A mass of molded green-sand placed against the side of a pattern which is under-cut. Before drawing the pattern, the false-cores are removed, and are restored before closing the flask. Also called a drawback. See *c*, Fig. 3188.

False-part. A flask temporarily filled with sand in which the pattern is sunk to a parting-line before ramming up the other side of the box which is to form the *drag*. After turning over, the false-part is broken up and the parting properly made.

Feeding-rod. An iron rod for keeping open the *head* or *riser* at which hot metal is added from time to time as the casting contracts in cooling.

Fettle. To clean castings, remove *gits*, *fins*, and *cores*.

Fin. A thin sheet of metal extending along the *parting-line* of a casting where the metal has insinuated itself between the parts of the mold.

Flask. The box or frame which contains the rammed sand forming the mold. The upper part is the *cope*, the lower the *drag*.

Flow gate. An opening from the mold to the surface; in it the metal rises as it is poured into the cast-gate and fills the mold.

Gagger. A double hook hung to the cross-bars of the top-part of a flask, and entering the sand which fills the deep part of a pattern, to enable the sand to be lifted out.

Gate. The opening through a mold into which metal is poured. An *ingate*. Also called *git*.

Gland. A bent rod of iron forming a double hook to lock the parts of a flask together.

Grain. A piece of wrought-iron to hold a core in position. A *chaplet*.

Green-sand. The damp sand of the foundry prepared for molding. See Sand.

Hay-rope. A twisted hay-band wound about a core-barrel in making large cores.

Head. A *flow-gate* or *riser* over the largest part of a heavy casting, in which the hot metal rises, and into which metal is poured from time to time as the metal contracts.

Horse-dung. Introduced into loam, as hair into plaster, to form a bond in dry-sand molds.

Ingate. The opening through a mold at which metal is poured in. A *gate*, *git*, *runner*.

Ladle. An iron vessel, coated with loam, and used to convey molten metal from the furnace and pour it into the mold. One form is a *shanks*.

Lantern. A perforated core-barrel, short, and of relatively large diameter.

Lift. The separation of the cope from the drag.

Loam. A mixture of sand and clay used in molding. See Sand.

Loam-board. A board resting on trestles, and holding the loam used in making cores.

Loam-plate. A flat cast-iron ring on which the *nowel* and *cope* rest in *loam-work*. See *b*, Fig. 3189.

Loosening-bar. A rod extending upward from the pattern through the sand, and which is struck from opposite sides to loosen the pattern in the mold before lifting the top-part.

Metal. The founder's term for cast-iron.

Nowo-sand. Facing-sand next to the pattern.

Odd-side. A permanent *false-part*.

Old-sand. The sand of the foundry floor, killed by use, and not fit for *facing*.

Open-sand molding. A mode in which molds are made in the floor of the foundry without any cope, and usually filled direct from the furnace.

Part. One portion of a *flask*.

Parting. The line of separation between the sand rammed in the respective boxes or parts of the flask.

Parting-line. The line upon a pattern below which it is im-

Digitized by Google

bedded in the *drag*, and above which it is in the *cope* or top-part.

Parting-sand. Sand free from clay, which is scattered over a green-sand surface where a parting is to be made.

Pattern. The counterpart of a casting in wood or metal from which the mold in the sand is made.

Pease meal. Dusted on as *facing* for molds in brass casting.

Picker. A steel rod with a sharp point, used in picking out small patterns from the sand.

Pickle. Dilute sulphuric acid used in cleaning castings.

Piercer. A vent-wire.

Pot. A crucible, generally of graphite.

Print. A projection on a pattern which leaves a space in the sand for supporting a core in position.

Rammer. An implement for compacting the loam around the pattern in the flask.

Red brick-dust. Sometimes used as a parting-sand.

Riddle. A sieve to mix sand on the floor of the foundry.

Riser. An opening through a mold into which the metal rises as the mold fills, and through which more metal is poured in as the mass contracts.

Run. Said of a mold if the metal insinuates itself along the parting or otherwise leaks out.

Runner. A channel leading from the gate to the space left by the removal of the pattern from the mold.

Runner-stick. A pattern for forming the gate of a mold.

Run-through. When metal is poured in at one gate and runs out at another. A process sometimes adopted in casting a piece solid to another piece already in the mold.

Sand. Crystalline particles of silica mixed with clay which confers tenacity. Used as a material for ramming around patterns in molding. See SAND.

Sand-burned. Sand partially fused by the heat of the metal and adhering to the casting.

Scoring. The bursting of a casting due to strain in contraction.

Scrap-iron. The spattered masses of iron, wasters, and pieces of iron which have been previously cast.

Shanks. The ladle in which metal is carried from the furnace to the mold

Shovel. The implement for heaping sand into the flask.

Shrinkage. The allowance of one eighth inch to the foot, which patterns are made larger than the casting required, to allow for shrinkage of the metal.

Shuttle. A spade-shaped implement by which the molder stops the flow into the mold in casting direct from the furnace

Sieve. A wire-cloth sifter for distributing the sand over the pattern.

Skimmer. A bar to keep back slag and dross when pouring from the ladle.

Slag. A basic silicate of iron floating on the metal in the furnace or ladle, and which it is the business of the skimmer to push back in pouring.

Slicker. A small, polished tool for smoothing surfaces of sand in the mold.

Sow. A large channel in the floor of a foundry to hold metal, when heavy castings are to be made without the use of the ladle.

Staple. A piece of iron driven into the sand and projecting therefrom to hold a core.

Steady-pin. One of the dowel-pins which form a part of the locking device securing together the parts of a flask.

Stove. The drying-chamber for molds and cores.

Strickle. A straight-edge used to remove superfluous sand from a flask after ramming up.

Strike. The same as strickle.

Strong sand. Tenacious from abundance of clay.

Sullage. The scum, slag, dross floating on metal.

Sullage-piece. An additional length on the upper end of a casting to insure compactness of the lower part. The sullage-piece is afterward removed.

Swab. A soft brush of frayed rope, used in wetting the parting-edge before drawing the pattern.

Swab-pot. An iron vessel to hold water for the swab.

Tap-hole. The opening from which iron flows from the cupola.

Tapping-bar. One for opening the tap-hole by removing the *bot* of clay.

Thickness. The portion of loam, in loam-molding, which represents the object to be cast.

Trestles. Frames on which the perforated core-barrels rest in pipe-molding

Trowel. A flat-bladed implement used in slicking and parting sand in the mold.

Under-cut. The parts of a pattern in which the sand would be broken by drawing the pattern perpendicularly. The difficulty is avoided by cores, drawbacks, or an additional part to the flask.

Vent. A channel by which air escapes from the mold.

Vent-wire. A sharp-pointed steel wire for piercing sand in the mold to allow escape of air.

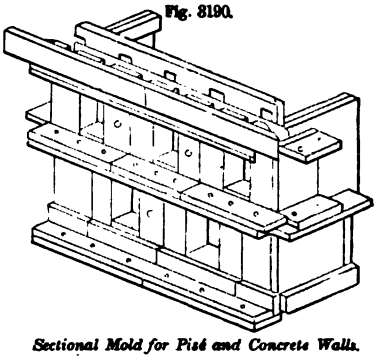
Waster. A spoiled casting; goes to the scrap-heap.

Watering-can. One with a rose to damp the molding-sand.

Weighting. Blocks put on a flask to keep the cope down under the upward pressure of the body of iron poured into the mold.

2. (*Building.*) A frame to give shape to a structure, as in the building of houses in concrete, béton, clay, cement, and what not. In the example, the molds are made in inner and outer sections, which sustain the joists and door and window frames, and between which the concrete walls are formed. The

Fig. 3190.

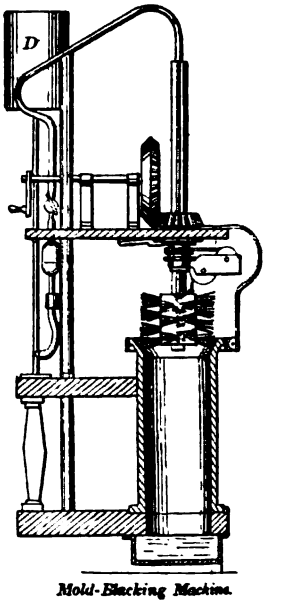


Sectional Mold for Pisé and Concrete Walls.

molds are perforated for admission of air, which supplies carbonic-acid gas. Composition used: sand, 19; hydraulic lime, ½; quicklime, 2.

3. (*Paper-making.*) Hand-made paper is made by a *mold g* and *deckle h*, Fig. 3188. The mold is an open, square frame with a wire-cloth bottom, and a little larger all round than the required sheet of paper. The *deckle* is an open frame, whose inner margin determines the size of the sheet of paper. The *deckle* being laid on the mold, the two are dipped into the pulp, of which a quantity is raised, the superabundance flowing over the edge. The mold being shaken, the water drains away through the wire-cloth, and the fibers become felted together and settle upon the wire. The *dipper* then removes the *deckle* and passes the mold to the *coucher*, who lets it drain a few seconds, and then *couches* the sheet of pulp upon a felt cloth. A stack of alternate sheets and felts to the number of 6 quires of paper, =144 sheets, forms a *post*, which is placed in a screw-press and consolidated.

Fig. 3191.



Mold-Blacking Machine.

4. (*Plastering.*) A thin board cut to a pattern and used in forming cornices, etc. (*k*, Fig. 3188.)

5. (*Shipbuilding.*) *a.* A full-sized pattern of the same figure and dimensions with the molding side of the piece which it represents. The mold may be of skeleton form, and may serve for several frames.

It is usually a thin plank cut to the form of a ship-timber, and serving as a templet for scribing the timbers for the workmen who saw, hew, and adze them into shape.

Digitized by Google

6. (*Gold-beating.*) The package of gold-beater's skin in which gold-leaf is placed for the third beating. It is first enveloped in vellum, 150 leaves with interposed ribbons of gold, one inch square, forming a *kutch*. The pieces, spreading to the size of the vellum, are cut into four pieces and interleaved with gold-beater's skin; 600 pieces and their skin form a *shoder*, for the second beating.

Being again divided into four pieces, they are again interleaved with gold-beater's skin, making 2,400. These are divided into three packages of 800 each, called *molds*, and receive the third beating.

Mold-black'ing Ma-chine'. One by which a loam-mold is blacked to give it a thin carbonaceous surface; the solution is known as *black-wash*, and is usually put on by a hand-brush; but in pipe and cylinder casting, the insides of the *copes* may be reached by a reciprocating and revolving cylindrical brush supplied through a hollow shaft and tube from an upper reservoir *D*.

Mold-board. 1. (*Plow.*) A curved plate extending back of the share, for overturning the furrow-slice.

The mold-*board*, as its name indicates, was originally of wood, and was first made of iron by James Small, of Berwickshire, Scotland, about 1764. He was the first to make a complete plow of iron and steel, all but the hand-holds for the grasp of the plowman.

Plows are called *right* or *left*, according to the direction in which the furrow-slice is laid. *Double mold-board* plows are those in which the breast is formed by two mold-boards meeting at an acute angle in front of the sheth, and turning the soil equally in each direction.

2. (*Founding.*) A board on which the pattern lies while being rammed. A *follow-board*.

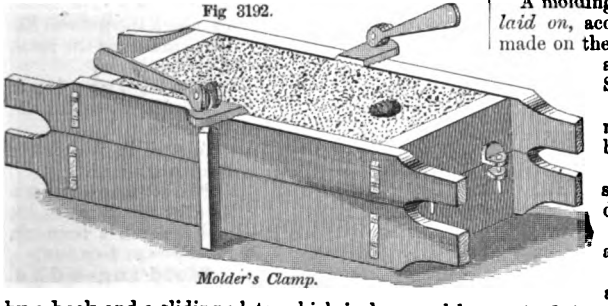
Mold-cis'tern. (*Sugar-making.*) *a.* The vat which receives the drippings from the sugar-loaves.

b. A tank in which the molds are soaked after being used.

Mold'er's Clamp. (*Founding.*) A frame by which the *parts* of a flask are tightly secured together, ready for the pouring of the metal into the mold.

In Fig. 3192, the parts of the flask are clamped

Fig 3192.



Molder's Clamp.

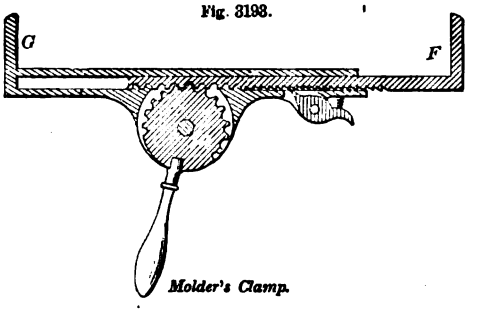
by a hook and a sliding plate, which is depressed by an eccentric pivoted to the shank of the hook.

Fig. 3193 has hooks *F* and *G*, which are drawn against the parts of the flask by pinion and ratchet. The ratchet-arm is worked within the hollow arm by a cog-wheel operated by a lever. Each arm has a hook on its outer end. The spring pawl engages the ratchet-arm to keep it in position.

Mold'er's Flask. (*Founding.*) The frame containing the mold in which metal is poured in casting. See *e*, Fig. 3190. See also MOLD; COPE; DRAG; FLASK, etc. See list under FOUNDING.

Mold'er's Ta'ble. (*Founding.*) A bench at which a workman stands in molding small objects.

Fig. 3193.



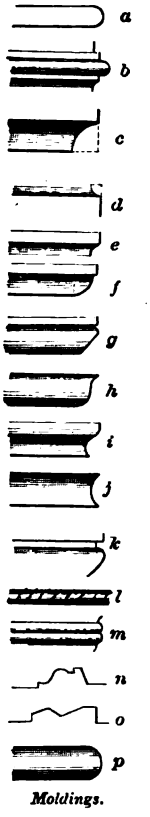
Molder's Clamp.

Mold-fac'ing. (*Casting.*) A fine powder sprinkled upon a pattern before covering the latter with loam. It is intended to increase the smoothness of the face of the casting.

Mold'ing. 1. (*Architectural Joinery.*) A mode of ornamentation by grooved or swelling bands or forms, following the line of the object.

a, bead, if small; *torus*, if large.
b, astragal or *bed.*
c, cavetto, hollow, casemate, or *cove*, according to circumstances or size.
d, apophygé, scape, spring, hollow congé, the *echinus* or quarter round. The *echinus* is a *swelling congé.*
e, fillet or *list*, if small; *fascia*, if large; *band*, when solitary; *cincture*, when separating the shaft from the capital or base.
f, Roman ovolo or *quarter-round.*
g, Grecian ovolo or *echinus.*
h, cyma-recta, ogee, talon.
i, cyma-reversa.
j, scotia or *trochilus.*
k, quirk.
l, cable.
m, double bead.
n, bolection molding.
o, canted molding.
p, torus. See JOINERY-FRAMING.

Fig. 3194.



Moldings.

A molding is said to be *stuck on* or *laid on*, according to whether it is made on the edge of the frame or on a detached strip. See STUCK-ON.

A *reeding* is a form of molding resembling a number of bands.

Lamb's tongue is a form sometimes adapted for window-sash.

A *raking* molding has a slanting overhang.

A *crowning* molding is a top member.

A *plain* molding is a mere band.

The student of paleontology finds numerous anticipations of architectural and other ornamentation in the strata of the earth. "In what is known as the modern Ionic the spiral of the volute is not all on one plane; it is a Euomphalus: in the central volutes of the Corinthian the spiral is an open one; it is a Lituite or Gyroceras: in the ancient Ionic it is either wholly flat, as in Planorbus or the upper side of Maclurea, or slightly relieved, as in the ammonites. There is no form of the volute known to the architect which may not be found in the rocks, but there are many forms in the rocks unknown to the architect. Nor are the spire-like shells less re-

Digitized by Google

markable for the rich and varied style of their ornamentation than the whorled ones. They are spires, pinnacles, turrets, broaches; ornate, in some instances, beyond the reach of the architect, and illustrative, in almost all, of his happiest forms and proportions. We detect among the fossils the germs of numerous designs developed in almost every department of art; but merely to enumerate them would require a volume. One form of the old classic lamp was that of the nautilus; another, that of *Gyphæa incurva;* the zigzag moldings of the Norman Gothic may be found in the carinated oysters of the green-sand; the more delicate frettings of similar form which roughened the pillars of a somewhat later age occur on Conularia and the dorsal spines of Gyracanthus. The old corals, too, abound in ornamental patterns, which man, unaware of their existence at the time, devised long after for himself." — HUGH MILLER.

2. (*Pottery.*) Articles of clay are molded upon a WHIRLING-TABLE (which see), or in molds which open and close, like those used in casting metals. In the latter case, the clay is usually rammed into the mold, but for some delicate objects the *slip* or creamy clay is poured into the mold, which is made of plaster, so as to quickly absorb the superfluous water of the filling adjacent. The central fluid portion being poured off, the clay adhering to the mold is allowed to dry, and the process repeated until the required thickness is obtained.

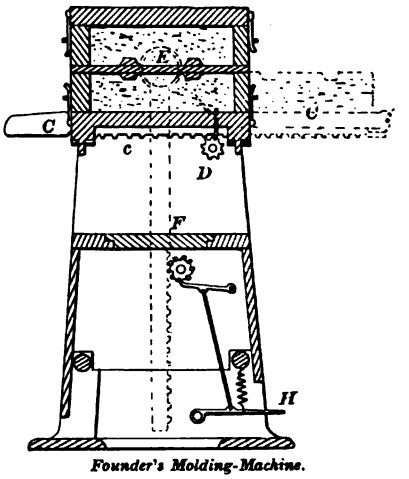
3. (*Shipbuilding.*) Giving the correct outline and depth to ship's timbers, etc. It is one part of the operation of FORMING (which see).

Mold'ing-ap'pa-ra'tus. (*Founding.*) A device or machine for molding. In that represented in Fig. 3195, the operations of molding, facing, drying, coring, casting, and stripping are carried on consecutively, without interfering with each other. The empty flasks from the part *A* of the C-shaped trench *A D D*, which is made somewhat shallower than the rest, are lifted by the crane *F* into *B*, where the molds are cored, tamped, and faced, after which they are lifted by the same crane into the oven *C* and dried. The oven has a door at each end, one communicating with *B* and the other with *D D*, into which, after drying, they are deposited by the crane *G*.

Here the metal is poured by a pot suspended from the crane *G*. When cool, the flasks are lifted by this crane on to the trestles *H H*, where they are delivered, cleaned, and replaced in *A* to again undergo the same series of operations.

In Horrobin's machine (Fig. 3196) the flask is placed on a sliding carriage moved by a rack and

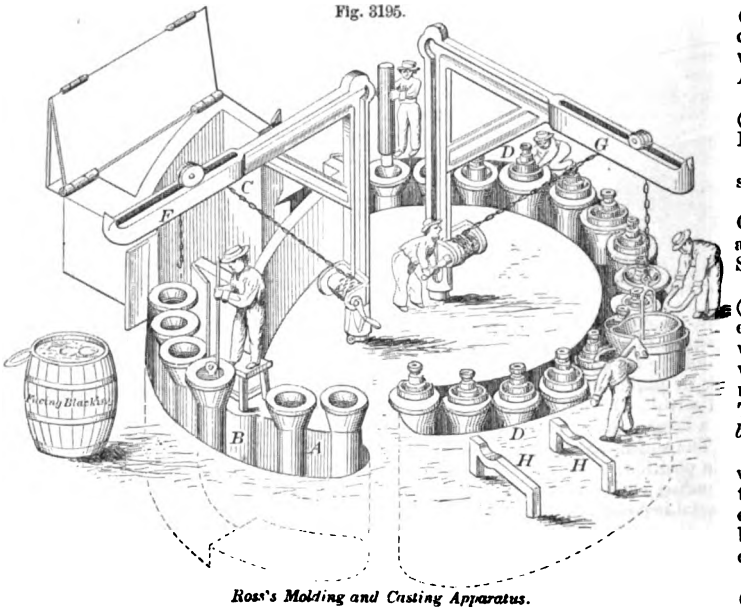
Fig. 3196.



Founder's Molding-Machine.

pinion *C D*. The follow-board *E* is journaled on top of the rack *f*, so that it and the flask may be lifted and turned over, in order that a mold just made may be examined while another is being made on the other side. The rack *F* is raised or lowered by depressing the treadle *H*, which releases a pawl from the rack-pinion, and turning a crank on the pinion-shaft.

Fig. 3195.



Ross's Molding and Casting Apparatus.

Mold'ing-board. (*Founding.*) The board on which the pattern lies when ramming the loam. A *follow-board.*

Mold'ing-box. (*Founding.*) See FLASK; MOLDING.

A *flask* in which the sand is rammed.

Mold'ing-crane. One for handling molds and flasks in a foundry. See FOUNDRY-CRANE.

Mold'ing-edge. (*Shipbuilding.*) That edge of a ship's frame which comes in contact with the skin and is represented in the draft. The other edge is the *beveling-edge.*

Mold'ing-file. A file with a concavity adapted to dress and finish molded surfaces. It is made by a swage and afterward cut.

Mold'ing-frame. (*Founding.*) The tem-

Digitized by Google

plet by which an object is shaped in loam-molding.

Mold'ing-hole. (*Founding.*) The cavity in the floor of a foundry in which large castings are made.

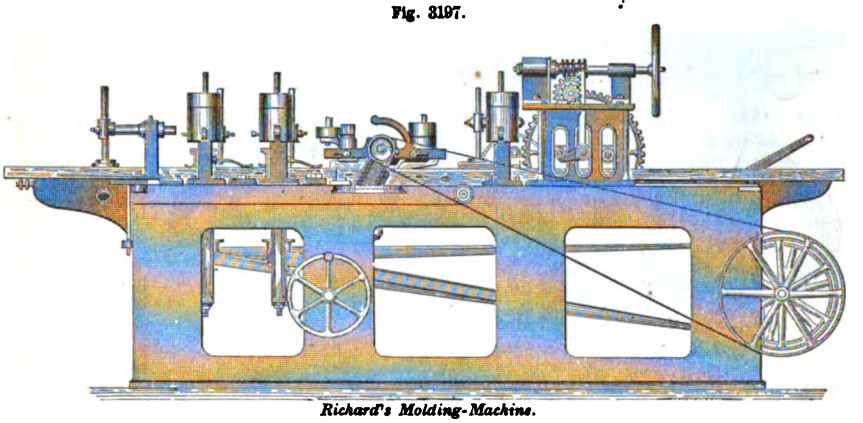
Mold'ing-loam. (*Founding.*) The mixture of sand and clay used in loam-molding.

Mold'ing-ma-chine'. 1. (*Wood-working.*) The rotary molding-machine for wood is enumerated among the inventions of General Samuel Bentham, previous to 1800. It had rotary cutters. One form of his machine was for making wave-moldings, and had an undulating bed.

There are several forms of the machine, one of which is a modified planing-machine; the other is an outgrowth of the same, but has a peculiar construction.

Fig. 3197 is a side elevation of a molding-machine

Fig. 3197.



Richard's Molding-Machine.

to plane four sides of the lumber. A roughing cylinder is placed in front of the main profile cylinder, to smooth the bottom of the lumber before it reaches the bed under the main cutters. The profile cutting on the under side is performed by the cylinder at the rear end of the machine. The cutter-heads are five in number, on steel spindles. The feeding mechanism is on top of the machine, raised above the cutting mechanism. The lumber is fed in at the end of the machine, gripped by the feeders, supported by the bed, and passed in contact with the revolving cutters in turn. See PLANING-MACHINE, WOOD.

Fig. 3198 is a perspective view of a machine for working heavy moldings, either three or four sides at one operation. The revolving head on the main spindle is slotted to receive a number of cutters, so as to make a molding of the profile required. The main feeding-roll is in the bed, and does not show in the figure; the adjustable swinging feeding-roll above is made in sections, and is so hung and geared as to be parallel with the lower feeding-roll. The lower horizontal cutter-head is in the bed, and does not

Fig. 3199.

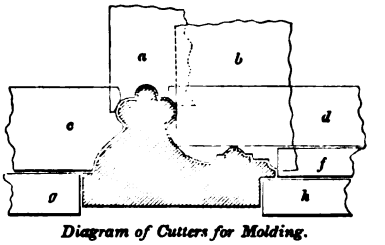


Diagram of Cutters for Molding.

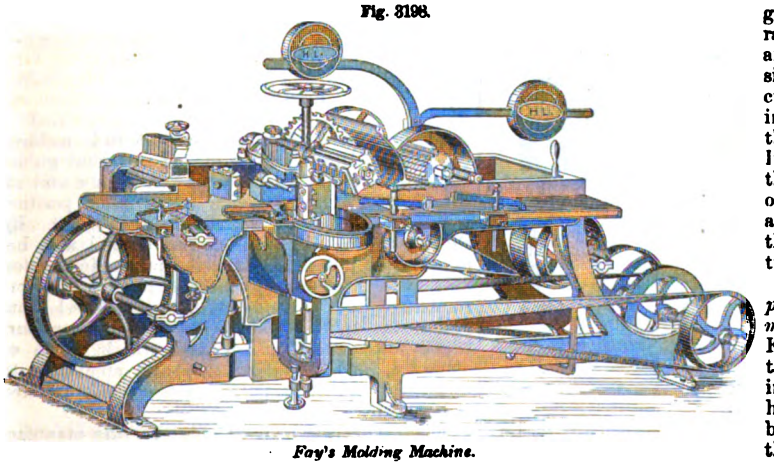
appear; the upper head and the side cutters, on vertical spindles, are shown. The latter are driven by crossed belts.

Fig. 3198.



Fay's Molding Machine.

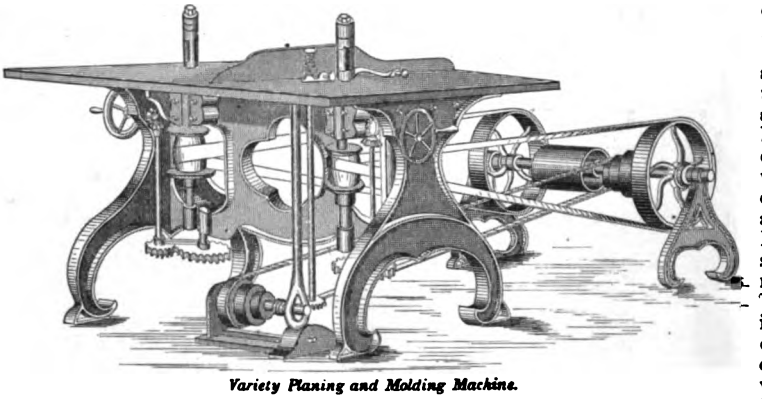
Fig. 3199 is a diagram showing the arrangement of cutters and their relative position to make undercut picture-frame molding, with rabbet for the glass and picture. It will be seen that of the side cutter-heads one has three knives and the other two; the upper head has two knives.

Another type of *planing and molding machine* is shown at Fig. 3200. A broad table rests upon an iron frame at the usual hight of a carpenter's bench, and rising from the surface near one

Digitized by Google

end are the heads of two vertical spindles or shafts, which project but a few inches. In the heads are planing-irons, shaped to suit the work required, and the heads form a guide or gage to the pattern to which the material to be dressed is temporarily attached by a few metallic points. The pattern being

Fig. 3200.



Variety Planing and Molding Machine.

carried past and against the heads while rotating, the material upon it is planed and molded to the shape of the pattern and knives used. By the graduation of the knives, the machine may be adapted to work of any size, making the heads even from one half of an inch to four inches in diameter; so that the machine may be used in doing delicate irregular woodwork.

It is now used in planing the wood handles to hair-brushes, and also in dressing plow-beams and the knees of ships.

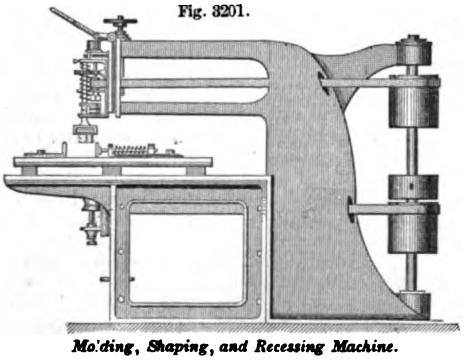
The engraving represents upon the table-top of the machine a guide, connected with which is a feed-roll, which receives power to move it from the pulleys beneath the table, and when attached completes the machine for doing straight as well as irregular work.

By the hand-wheel arrangement, represented at each side of the machine, the spindles are raised or lowered, as occasion requires, adapting the cutters to the thickness of the material operated upon.

This machine is analogous to the *milling-machine* for metal.

Fig. 3201 is a side elevation of a molding, shaping, and recessing machine, applicable to a number of

Fig. 3201.

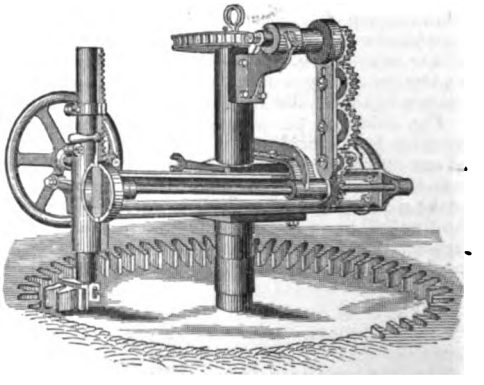


Molding, Shaping, and Recessing Machine.

purposes, among which may be mentioned cutting curvilinear moldings, sticking circular and straight sash-bars, molding, rebating, and grooving square or circular sash-frames, forming moldings round raised door-panels; molding, chamfering, or edging flat ornamental balustrades, to patterns; forming the housings in string-boards for stairs; sinking recesses of any design, etc. The machine is furnished with top and bottom vertical cutter spindles, driven from an intermediate shaft at the back. The upper spindle is lowered into the work by depressing a handle; directly the handle is released, the cutter rises from the work through the agency of a strong spring affixed to the slide. For recessing, suitable stops are provided, to regulate the depth. When striking moldings, a fixed table is employed, but for recessing, curvilinear work, etc., a table on friction rollers is substituted. The lower cutter-spindle revolves in a reverse direction to the upper, and is useful for certain kinds of work. See CARVING-MACHINE.

2. (*Founding.*) Fig. 3202 is a view of a molding-machine for gear-wheels, in which a pattern is used corresponding to a small portion of the gear to be molded. This pattern includes two teeth and the

Fig. 3202.



Gear-Molding Machine.

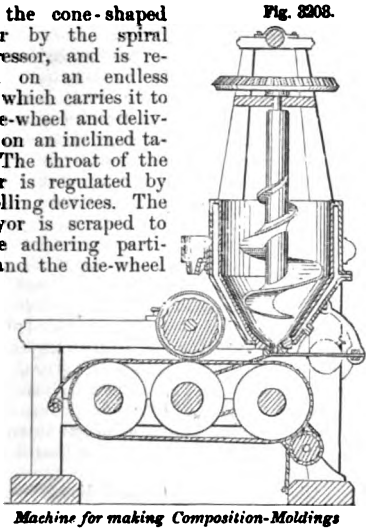
interdental space, when spur-gears are to be molded. It is attached to the lower end of a vertical guide-bar, which slides in ways formed at the end of a horizontal support, which has a radial position relatively to a central vertical spindle or arbor. By this means the pattern is carried around, and, being made to descend, makes the proper impression for that portion of the gear-wheel or pulley which corresponds to it. It is used to mold gear-wheels from nine inches up to six feet in diameter, — either spur, bevel, miter, mortise, or worm wheels, plain or shrouded, — and it is also equally applicable to molding fly-wheels or pulleys, either whole or fitted in segments.

3. (*Plastic-work.*) A machine for the manufacture of composition-molding. The material is driven

Digitized by Google

from the cone-shaped hopper by the spiral compressor, and is received on an endless apron which carries it to the die-wheel and delivers it on an inclined table. The throat of the hopper is regulated by controlling devices. The conveyor is scraped to remove adhering particles, and the die-wheel

Fig. 3203.

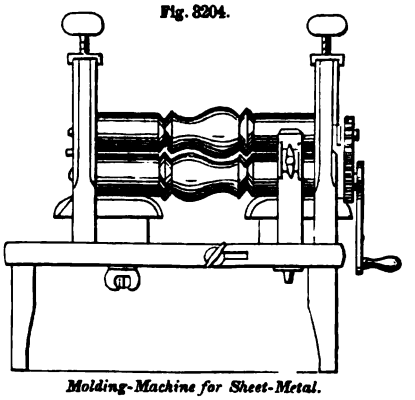


Machine for making Composition-Moldings

oiled to prevent adherence of the composition. The principle is the same as some of the brick, tile, and pipe machines (which see).

4. (*Sheet-metal Working.*) A kind of rolling-machine for molding sheet-metal to shape for cornices, balusters, and other purposes. It consists of a pair of rollers of counterpart form, between which the sheet of metal is passed to give it the required outline.

Fig. 3204.



Molding-Machine for Sheet-Metal.

Mold'ing-mill. A planing-mill for shaping timber. See MOLDING-MACHINE, 1.

Mold'ing-planes. Joiners' planes for making moldings, and having various patterns, or concave and convex soles to form parts of moldings. Such as *hollows* and *rounds*. *Match-planes.*

plow. Used for molding or forming ridges, striking water-courses, or hilling-up potatoes; so constructed as to thoroughly turn the soil, burying the surface and bringing up the bottom. That shown is made entirely of iron, having a trussed beam and front wheel, and may be used for splitting ridges; the breast is laterally expansible, and the penetration of the share is regulated by the draft-chain at the clevis.

Mold'ing-saw. One or a number of circular saws for blocking out strips for ornamental moldings.

The strips are fed repeatedly to the saw at different angles, and the general outline of the desired molding approximated. The work is generally completed by revolving planes.

Mole. 1. (*Husbandry.*) A cylindrical plug of iron, three or four inches in diameter, and with a sharp point, drawn or driven through the subsoil to make a drain.

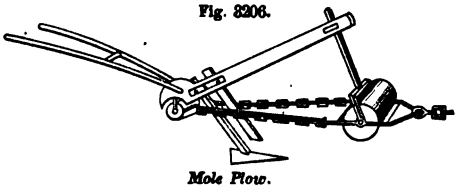
2. (*Maritime Engineering.*) *a.* A jetty or structure erected before a port so as to partially inclose a harbor or anchorage, and protect it from the violence of the waves in the offing.

b. A pier of masonry; one is described by Herodotus as extending around the harbor of Samos.

3. A mausoleum of peculiar form, as the mole of Hadrian, now known as the Castle of St. Angelo, Rome.

Mole-plow. The mole-plow has a pointed iron shoe, which is attached to the end of a standard and drawn along underground, making a track like that

Fig. 3206.



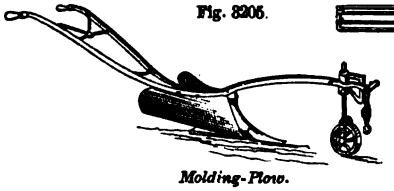
Mole Plow.

of a mole, establishing a duct to lead water from the subsoil, pressing the earth away, but not purposely disturbing the surface.

It is said to have been invented by Adam Scott (British), and will be easily understood by the illustration. The work is all beneath the soil, in positions where a surface drain is inadmissible, the thin colter to which the *mole* is attached only making a mark which is soon obliterated. It was used in draining the marshes of Essex, England, during the latter part of the last century.

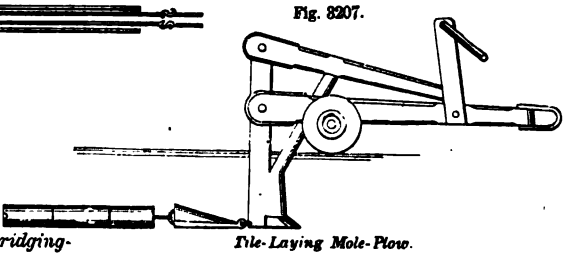
In a modification, the mole is attached by a short chain to the bottom of the sharp standard, to permit the *mole* to avoid obstacles, and by lessening its rigidity increase the ease of traction. Fig. 3207 is a tile-laying mole-plow. The cutter-bar is pivoted to the carriage, and adjustable to vary the presentation of its foot by means of an upper beam to which it is attached and braced. A mole trails behind the

Fig. 3205.



Molding-Plow.

Fig. 3207.



Tile-Laying Mole-Plow.

Mold'ing-plow. A plow with two mold-boards to throw the soil right and left. A *ridging-*

Digitized by Google

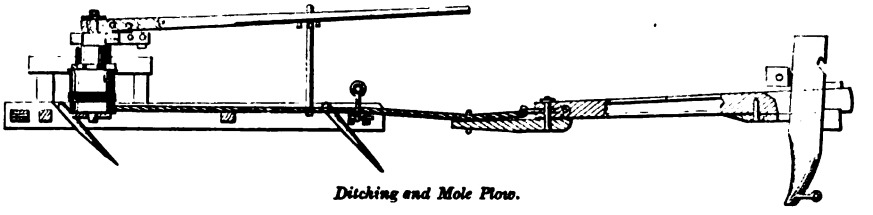
cutter-foot, and by means of a cord, hooks, and cross-bar the tiles are drawn in behind the mole.

A mole-plow for laying tiles was made about 1850, and exhibited by Foules, the inventor, at the meeting of the Royal Agricultural Society of England of that year.

Attached to the mole was a rope, upon which the sections of tile were strung, and the mole as it progressed drew in 300 feet of tiling after it. A hole was dug at each commencement of operations. See DRAIN-TILE.

It is sometimes drawn by four or six horses, and, perhaps, more often by a rope from a capstan, as in Fig. 3208, in which the capstan is shown anchored

Fig. 3208.



Ditching and Mole Plow.

in position, and the standard of the mole-plow has a clevis for the attachment of the mole.

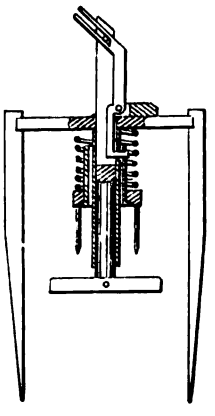
The *mole-plow* is described in White's English patent for a draining implement, 1797. It is thus described in a report, November, 1797: —

"The principle of this invention consists in the patentee's mode of forming a sort of subterraneous channels, cavities, soughs, or drains, from every part of the ground to be drained, which channels run into a principal drain or ditch, cut by hand in the usual way. These subterraneous channels he forms by a particular species of share, foot, or wedge, affixed to a sort of plow, which is drawn by horses in the usual way.

"In the beam of the plow is fixed a vertical plate of iron, about 24 inches long, and called, from its sharp steel edge, the *cutter*. To the bottom of this cutter is fixed a solid *wedge*, *foot*, or *share* of cast-steel or wrought-iron, 12 inches in length, 2¼ to 3 inches thick, and 2½ to 3 inches deep at the base, and terminating (forward) in a sharp point. This *wedge*, before the plow is put in motion by the horses, is introduced into the ground as deep as may appear to be necessary; and, by its passage under the surface, it forms the subterraneous channels which carry off the moisture to the main or principal drain.

"To lessen the resistance against the sharp edges of the cutter and wedge, in their passage through stiff soils, a circular or rolling cutter may be fixed immediately before the perpendicular cutter, or a shorter vertical cutter, at the pleasure of the maker."

Fig. 3209.



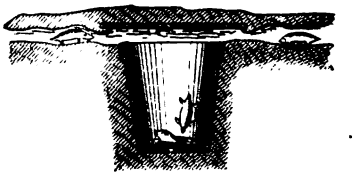
Mole-Trap.

Mole'skin. (*Fabric.*) A strong cotton twilled goods for men's wear. A kind of fustian, cropped or shorn before dyeing. *Beaverteen.*

Mole'trap. One placed in a mole-burrow to catch the mole. There are several kinds. In one, the mole, in attempting to effect a passage underneath the cross-bar on the lower end of the trigger-staff, actuates the trigger, and releases the tube carrying the prongs, and is consequently impaled by the latter.

Fig. 3210 shows a flower-pot placed with its mouth on the level of the track of the mole. Over the top of this receptacle a piece of board is placed, leaving a space of about three inches between it and the edge of the pot, so that dirt from above will not fall into the latter. The openings of the run lead into this space. The earth is replaced and the surface of the ground restored. The mole, in following his usual road, blindly comes to the orifice leading to the pot, into which he tumbles.

Fig. 3210.



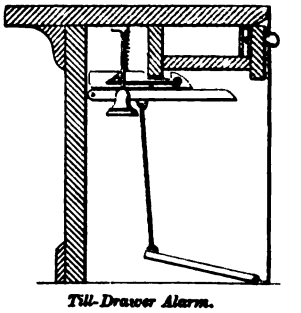
Mole-Trap.

Mol'le-bart. (*Agriculture.*) A Flemish implement consisting of a large shovel drawn by a horse and guided by a man. A *mold-board* or *earth-scraper*.

Mol-yb-de'num. A metal: Equivalent, 46; symbol, *Mo.*; specific gravity, 8.62; it gives a greenish flame under the blow-pipe; a salt of this metal is used as a test for soda. It is not much used in the arts.

Its sulphide is a soft black mineral frequently mistaken for graphite. In 1778 the Swedish chemist Scheele decided that it was really a different mineral; and in 1782, Hjelm prepared from it a new metal, to which was given the name molybdenum, the sulphide having received the name of molybdenite. It may be distinguished from graphite as follows: On unglazed porcelain the former gives a greenish streak and graphite a black; molybdenite is decomposed by nitric acid, leaving a white or grayish residue; graphite is unacted upon by acids; on charcoal before the blow-pipe the former gives a strong sulphurous odor and coats the coal with crystals of molybdic acid; graphite is infusible, but at a high temperature with access of oxygen burns without flame or smoke. Molybdenum is not usually met with in large quantities, but has been found in crystals and plates at various places in the United States. See GRAPHITE.

Fig. 3211.



Till-Drawer Alarm.

Digitized by Google

Mon'ey-draw'er A-larm'. A device which strikes a bell when the till-drawer is opened. A cleat on the lower rear portion of the drawer engages a latch, and rings the bell, when the drawer is opened or closed. A treadle withdraws the latch to avoid the noise. A spring wire locks the drawer, and is unlocked by the motion of the knob.

Mon'ger. A small fishing-vessel.

Mon'i-tor The popular name for a class of American iron-clad vessels, having one or more turrets, and a peculiar formation of hull. So called from the first vessel of this construction, built for the United States by Captain John Ericsson, and launched early in 1862.

The original "Monitor" was based on a system proposed by Captain Ericsson to the Emperor Louis Napoleon in 1854. In 1855 Captain Coles of the Royal Navy proposed a system of revolving turrets to the British government, which was adopted after the "Monitor" had demonstrated the value of the invention. Captain Coles was lost in the iron-clad frigate "Captain," a vessel of his own construction, in a gale off Cape Finisterre in 1870. See Plate IV. for a view of the *Captain*.

Prior to the inventions of Ericsson and Coles was a proposition of Mr. T. R. Timby, of Massachusetts, who sent drawings of his proposed turret ships and batteries to the United States Patent Office in 1843. His right to the invention was afterward recognized by the United States, and a royalty paid to him. The evidence tends to show that neither one of these engineers was aware of the invention of the others prior to the completion of his own.

The contract for building the "Monitor" was awarded September 16, 1861. Captain Ericsson says: "In order not to lose time, the Secretary ordered me to 'go ahead at once.' Consequently, while the clerks of the department were engaged in drawing up the contract, the iron for the keel-plate of the 'Monitor' was drawn through the rolling-mill."

The contract for Captain Ericsson's battery specified that she was to be 172 feet long, 41 feet beam, 11½ feet hold, 1,255 tons displacement. She was to be completed in 100 days.

The construction of the "Monitor" was different from that of any vessel preceding her. Besides the revolving turret and low deck, the upper part of the hull had a square projection over the lower part, some 6 feet wide on the sides and 25 feet astern. This "overhang" served to make her much steadier in a sea, but was supposed to be the cause of her final loss. The deck was 18 inches above the water-line, and composed of one-inch plates of rolled iron. The turret was 20 feet in diameter and 9 feet high, built of thicknesses of one-inch rolled plates, and covered with a grating of railroad bars supposed to render it bomb-proof, with a roofing above to keep out water. The turret was pierced for two guns, and carried two 11-inch Dahlgrens. The guns and turret rested on a post or pivot amidships, which supported the whole weight, and was turned by the engines. The boilers and engines were aft, leaving the forward part of the hold for quarters for the crew and storage of ammunition. The pilot-house was forward, and had lookout-holes for the steersman or commander. (See also Plate IV., opposite page 150.) She was described by the Southern journals as "a black Yankee cheese-box on a raft."

The engagement of the "Monitor" and "Merrimac" in Hampton Roads, March 9, 1862, was an event of history, and need only be mentioned here as having decided the fate of wooden vessels for naval contests.

At that time the "Monitor" undoubtedly proved herself the most formidable craft afloat.

Subsequent engagements with shore batteries pointed out a few defects in construction, the worst one being the location of the pilot-house forward of the turret, interfering with the pointing of the guns in that direction. In subsequent monitors the pilot-house was mounted on the turret. Some other minor changes were also made. The original "Monitor" maintained her supremacy until her loss in a heavy storm off Hatteras, December 31, 1862. She is supposed to have been strained in falling with the seas, and parted between the lower hull and the overhang, carrying down four officers and twelve men with her. A part of the crew were saved by the steamer "Rhode Island."

After the success of the "Monitor," a large number of iron-clad vessels of similar or analogous construction were built for the United States government. The "Weehawken," one of the earliest, was plated with 6-inch armor on deck, 11 inches turret, and carried one 11 and one 15 inch gun.

In an engagement between the "Weehawken" and the Confederate iron-clad steamer "Atlanta," June 13, 1863, the latter was disabled at the fourth shot from her antagonist, and surrendered, having lost 16 men wounded and 40 knocked down by a 15-inch shot which broke through her 4-inch iron and 18-inch timber armor, although striking at an angle of 50°.

In the various engagements with the fortifications at Charleston, the "Weehawken" was struck 187 times by shot and shell without serious damage to vessel or crew.

Admiral Dahlgren reported that the nine iron-clads of the monitor pattern, during the operations against Morris Island, fired 8,000 projectiles, weighing 365 tons, and were struck 882 times, mostly by 100-pound shot, without receiving any very severe injuries. In giving his opinion as to the comparative value of iron-clad vessels, Admiral Dahlgren says: —

"The armament of the monitors could be perfected to give all desirable rapidity of fire, but by no contrivance could a broadside vessel be enabled to use much heavier guns than those now mounted. . . . . There remains to the monitors the advantages of lighter draft, choice of guns from the heaviest to the lightest, defensibility, and direction of fire around the whole circle; consequently the ability to carry a heavy battery into the least depth of water, with equal power of offense and defense in any direction, and that with half the number of guns carried in broadside by another vessel."

Admiral Porter, after a lengthened experience with all sorts of iron and wooden vessels in action under almost all possible circumstances, gave his opinion that the monitors built on the Western rivers were the most powerful vessels of war ever launched. He says: "The first monitor was a perfect success, and capable of defeating anything that then floated." The one first completed at Cincinnati, in 1864, he thought, "could commence at Cairo and, going down the river, destroy everything we have on these waters, unless they ran away"; and this without disparagement to the powerful fleet of vessels then on the Mississippi, several of which had received over a hundred shots each, while under the Admiral's command, without apparent damage. Of the monitors at Charleston, he says: "They have done what no other vessels ever built could possibly have accomplished."

Some 50 monitors were built for the United States government, between the years 1861 and 1867. Of

Digitized by Google

these, some have one, some two, and some three turrets, each turret to contain two guns. The general principles were substantially the same in all, and the Ericsson plan of iron-clad vessels may be said to cover nearly everything in the way of armored ships now in the United States navy. The guns mounted on the monitors are generally 15-inch Dahlgrens, carrying a projectile of 450 pounds. A few 20-inch guns, to throw a shot of 1,100 pounds, have been made, but these are now at the Navy Yard in Brooklyn, and none have yet been tried on shipboard.

The British Admiralty adopted a modified form of monitor or turret vessel, constructed according to the plan of Captain Coles, who built some very formidable vessels; but, in his efforts to increase the offensive efficiency, overloaded the vessels with upper works. This was most apparent in the "Captain," which is shown in Plate IV. (opposite page 150), in a group of iron-clads, American and British. This vessel capsized off Cape *Finisterre*, July, 1870, and was indeed the "end of earth" to the crew of 500 officers and men, and also to Captain Coles, who went down with her. The "Captain" was a double-turreted vessel, each turret carrying two 25-ton guns; armor of from 6 to 10 inches thickness, and had other upper works, fore and aft, also pierced for guns.

The same plate also shows the very formidable vessel, the single-turreted "Glatton," which was selected to be a target for 600-pound elongated projectiles of the "Palliser" order. She bore it very satisfactorily. In the same group is also the "Thunderer," a double-turreted vessel of a favorite class. It may be described as a monitor based upon the American models, but with variations introduced with a view of removing the more objectionable features of the monitor system. Thus, instead of having as low a freeboard as possible, a hight of four feet six inches has been allotted to the hull above the water-line; the turrets, instead of being exposed, are protected by a powerful breastwork; and, instead of being constructed upon as small a scale as possible, she has been built on a scale sufficient to enable her to carry an armament of four 35-ton guns, with the capacity of storing during a voyage a supply of 1,750 tons of coal. With such capabilities as these, she has a burden of 4,500 tons, a length of 285 feet, and an extreme breadth of 62½ feet; and, large as these proportions are, one of the few defects the British Committee of Ships' Designs find in her is that she is not large enough, and that in future such vessels should be built upon a larger scale than either the "Thunderer" or the "Devastation." See IRON-CLAD.

Mon'i-tor-car. (*Railway.*) One having a central longitudinal raised portion in the roof, on the sides of which portion are openings for ventilation and panes for light.

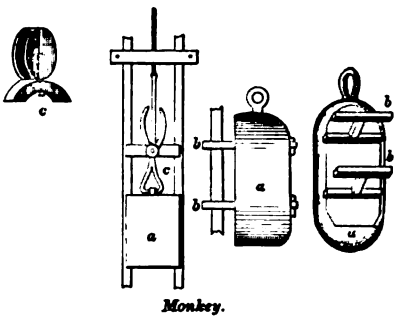
Monk. (*Printing.*) A blacker portion in a printed sheet; a dark patch. A blackened, wasted impression.

Mon'key. 1. The weight (*a*, Fig. 3212) of a pile or post driver, which is raised by a grapple and chain, and, being detached, is allowed to fall in its guides on to the head of the pile. The weight is attached to the chain by a dog *c*, which is caused to relax its grip by a trigger, or by coming in contact with a stop placed at the required hight.

At the back of the *monkey*, or *ram*, are two frames *b b* in the form of an H, which serve to guide the weight when rising or falling. See PILE-DRIVER.

2. (*Forging.*) A vertical hammer, consisting of a long bar of iron, running loosely through an eye, several feet above the anvil, and terminating at foot in a mass of iron, called the *ram*. The shaft is raised by a chain and drum driven by the engine, and has an automatic releasing apparatus, which is regulated to drop the monkey at the required

Fig 3212



Monkey.

hight, say with a range of from 2 to 5 feet. The monkey has a horizontal range of, say 20 inches, and is made to drop upon the spot required by means of guy-rods in the hands of two workmen.

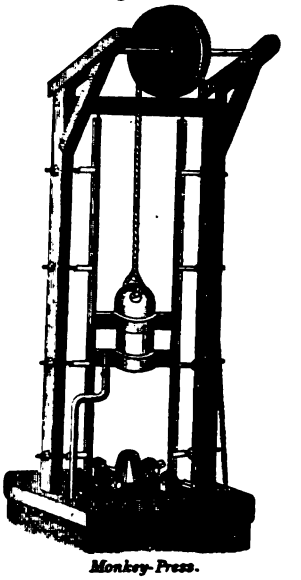
Mon'key-block. (*Nautical.*) A single block (*c*, Fig. 3212) strapped to a bridge-piece which is bolted to the deck or other object.

Mon'key-boat. A small boat used in the docks.

Mon'key-en'gine. A form of *pile-driver* having a *monkey* or *ram* weighing about 400 pounds, moving in a wooden frame. The monkey is held by a staple in a pair of tongs, and is drawn up 10 or 15 feet, or higher if necessary, by means of a winch. At the top of the lift the handles of the tongs come in contact with two inclined planes, which cause the tongs to open and drop the monkey. The tongs, being then lowered, become self-engaged with the staple, and so the work proceeds. See PILE-DRIVER.

Mon'key-ham'mer. A drop-press in which the hammer is a falling weight; called by the same name as the hammer of a pile-driving machine. In it various articles of jewelry, etc., are stamped out, the strip of gold being laid upon the lower die and impressed between it and the upper die, which descends in guides when the workman slacks the rope by raising the stirrup.

Fig. 3213.



Monkey-Press.

Mon'key-press. A hammer in which the driver consists of a *monkey* which is alternately raised and dropped, sliding in guides. One form of *power-hammer*.

Mon'key-pump. The sailor's name for the sucking straw introduced at a gimlet-hole in a wine-cask. This is as old as Xenophon, who describes this mode of pilfering from the wine-jars of Armenia.

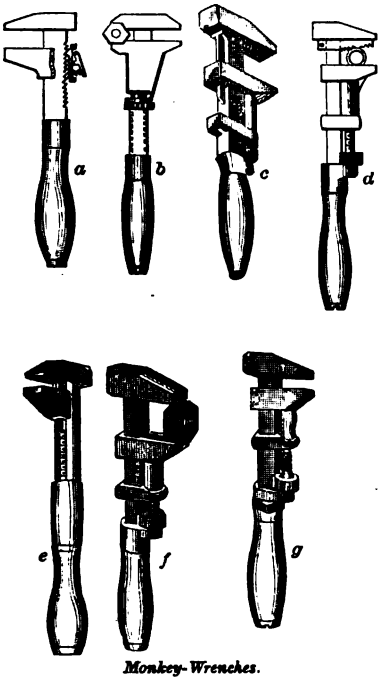
Digitized by Google

Mon'key-rail. (*Nautical.*) A supplementary rail, above and lighter than the quarter-rail.

Mon'key-tail. A small iron crow-bar used by naval gunners.

Mon'key-wrench. A spanner with a movable jaw. The cut shows several kinds.

Fig. 3214.



Monkey-Wrenches.

a has a spring-dog on the back, catching into a ratchet.

b has one jaw for hexagonal and another for square nuts.

c shows a strong form with a spline.

d has a serrated jaw to grasp a pipe.

e has a screw concealed in the stock.

f has a capacity for gripping a hexagonal nut by the points of its jaws.

g is an ordinary machinist's wrench of good quality.

Monk-seam. (*Nautical.*) A double seam of a sail made by overlapping selvages and sewing both edges.

Mon'o-chord. (*Music.*) 1. An ancient instrument with one string which was played as a guitar. It grew into a *manichord*, in which numerous strings were played by quills. See MANICHORD; PIANOFORTE.

2. An instrument for experimenting upon the mathematical relations of musical sounds. It consists of a single string, stretched between two bridges, one or both of which are movable, and which stand upon a graduated rule, for the purpose of readily changing and measuring the length of the part of the string involved in the vibration. (WEBSTER.) Sometimes called the *harmonical canon*.

Mon'o-chro-mat'ic Lamp. A lamp fed with a mixture of a solution of common salt and alcohol. It gives a yellow light and a ghastly appearance to the human face, objects appearing yellow or black. Useful in photographic studios.

Mo-noc'u-lar Mi'cro-scope. A microscope adapted for one eye, in contradistinction to a *binocular* instrument.

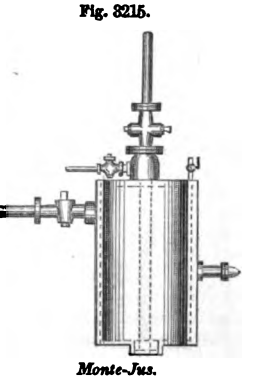
Mo-noc'u-lus. (*Surgical.*) A bandage to retain a topical application over the eye.

Mon'o-gram. A cipher composed of two or more letters interwoven as an abbreviation of a name. Monograms were common as distinctive marks on ancient coins, and were also used as devices on seals.

Mon'o-lith. A single column or block. The term is applied to such erections as the obelisks of Egypt, some of which are now in Rome and Paris. (See OBELISK.) The term *monolithic* is also applied to structures in which the blocks are immense, in some cases reaching from the foundation to the entablature, as in the United States Treasury, Washington. This building is said to have larger stones than any used in the pyramids of Egypt, and to be of a more massive construction in respect of the size of its stones than any other building in the world, except the church of St. Isaac at Petersburg, Russia.

The largest existing monolithic temple in Egypt is that of Tel-el-mai, on the Delta. It is 21 feet 9 inches high, 13 feet broad, and 11 feet 7 inches deep. This size is much exceeded by the dimensions given by Herodotus of the temples of Amasis and Latona, which were also, we are informed, on the Delta. The former one, he states, required three years to transport, with the aid of 2,000 laborers, from Elephantine to Saïs, a distance ordinarily of twenty days' Nilotic navigation. The temple of Latona was still larger. "The most wonderful thing," says Herodotus, "that was actually to be seen about this temple was a chapel in the inclosure made of a single stone, the length and hight of which was the same, each wall being forty cubits square [sixty feet], and the whole a single block. Another block of stone formed the roof, and projected at the eaves to the extent of four cubits." According to these measurements, supposing the walls to have been only six feet thick, and the material granite, as in all other monoliths, this monument would weigh 7,000 tons, being 76,032 cubic feet, without the cornice, which was placed on the roof. This capstone would weigh 2,400 tons, if six feet be taken for its thickness. If any doubt exists respecting the ability of the ancients to transport and uplift such enormous masses of stone as these, it is set at rest by M. Jomárd, the celebrated Egyptologist, who gives a sketch, in his work on Egypt, published by the French government, of a huge block of granite situated almost a quarter of a mile from the modern town of Syene, where it was abandoned for some unknown reason while on its way from the quarry. It bears numerous traces of instruments in the work on its surface, as well as evidences of its having been intended for a colossal statue. M. Jomárd's dimensions are, — the largest, 22$\frac{2}{10}$ meters, and for the body and back 6$\frac{1}{2}$ meters, or about 72, 21, and 21 English feet, which, at 13 cubic feet per ton, yields nearly 2,500 tons. See also MASONRY, where the stones of Baalbek are noticed.

Fig. 3215.



Monte-Jus.

Monte-jus. (*Sugar.*) A force-pump by which the juice from the cane-mill is raised to the clarifiers on the story above. It consists of a vessel with

Digitized by Google

a sunken well in the center of the bottom, and having three pipes: one by which the juice is received; another whose open lower end is near the bottom of the vessel, and by which the juice is discharged; a third by which steam is admitted. Each has a valve. The cistern being charged and the induction valve closed, steam is admitted, which presses on the surface of the liquid and drives it out by way of the ascending pipe. The valve in the steam and eduction pipes being closed, the steam condenses, the induction pipe is opened, and the cylinder refills. Repeat the operation.

Mon'ton. A heap of ore; a batch under process of amalgamation, varying in quantity in different mining districts.

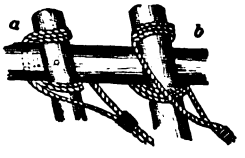
Moon-knife. A knife employed by skinners. The blade has a crescent shape, and is sharpened on its convex edge.

Moon-rak'er; Moon-sail. (*Nautical.*) A sail sometimes carried above the sky-scraper.

Moon'stone. A variety of adularia of a white color and opalescent reflections.

Moor'ing. (*Nautical.*) *a.* A sailor's bend for a cable or hawser to a bollard, post, or ring, for a ship or a flying bridge.

Fig 3216.



a, square mooring.
b, crossed fastening, the rope being crossed at the back.
c, simple fastening.
d, loop-fastening.

Mooring-Bends.

e, Lark's-head fastening to running knot. See BEND; CHAIN-FASTENING; WATERMAN'S-BEND.

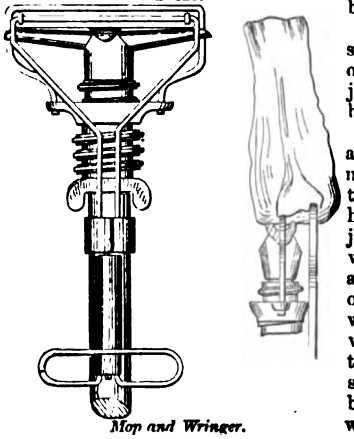
b. A submarine holdfast in the ground. See ANCHOR; SCREW-PILE; MUSHROOM-ANCHOR.

Moor'ing-swiv'el. (*Nautical.*) A chain over the bow, having the strength of the two cables to which it is swiveled. It enables a ship to ride from two anchors and swing without fouling.

Moot. (*Shipbuilding.*) *a.* A gage-ring for determining the size of tree-nails.

b. A piece of hard wood, hooped with iron at both ends, used in block-making.

Fig. 3217.



Mop and Wringer.

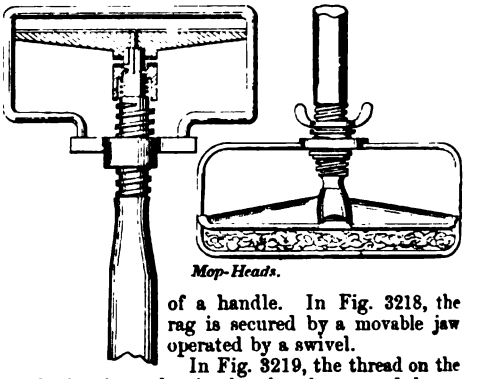
Mop. A scrubbing-rag or bundle of junk secured by a handle.

In the example of a domestic mop, the rag is held between jaws, one of which is movable, by means of a screw. A wringing device is attached, consisting of a bent wire, which is passed through the mop and secured to the handle; to use the wringer, detach the wire and turn it in the hand, twisting the mop-rag.

Mop-board. (*Carpentry.*) A wall-board next to the floor of a room. A *skirting-board.*

Mop-head. A clamp for a mop-rag on the end of a handle. In Fig. 3218, the rag is secured by a movable jaw operated by a swivel.

Fig. 3218. Fig. 3219.

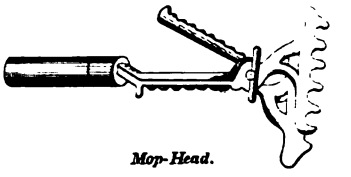


Mop-Heads.

In Fig. 3219, the thread on the handle has its socket in the thumb-nut, and the reverse thread on the latter has its socket in the collar of the yoke.

In Fig. 3220, the mop-cloth is clamped between toothed jaws, whose shanks are hinged and fastened by a ring.

Fig 3220.



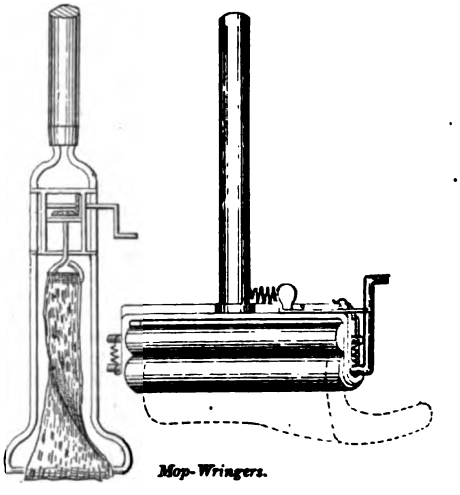
Mop-Head.

Mop-nail. A flat-headed nail, used in securing a bunch of junk or rope-ends to a handle in making a mop such as sailors use.

Mop-stick. (*Music.*) A vertical damper-rod at the end of the key in the old piano-forte movement, single action. When the key was depressed, the mop-stick was raised and the damper therewith. As the key rose, the damper fell back on to the string.

Mop-wring'er. (*Domestic.*) A device to wring

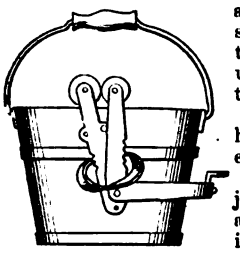
Fig. 3221. Fig. 3222.



Mop-Wringers.

Digitized by Google

Fig. 3223.



Mop-Wringer.

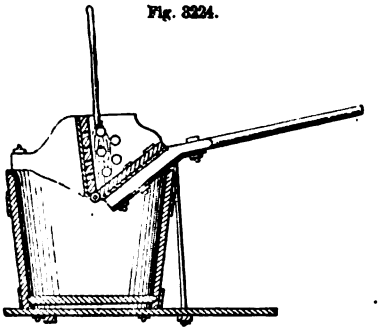
or squeeze the water from a mop. In Fig. 3221, the sliding frame with the twisting device is drawn up near the handle when the mop is to be wrung.

The example (Fig. 3222) has a pair of wringing rollers.

In Fig. 3223, the roller jaws are attached to a pail, are approached by a clasping spring, and opened by pressure on a treadle.

In Fig. 3224, the perforated boards are hinged together, the lower one is fixed, and the upper one has a lever and side-strips.

Fig. 3224.



Mop-Wringer.

The mop is pressed between them and drains into a bucket.

Mo-quette'. A fine tapestry or Brussels carpet. A species of Wilton carpet.

Mor'dant. A substance applied to a fabric to give a fixity to the dye.

1. (*Dyeing.*) Mordants were known to the natives of India, and perhaps of Egypt, in the time of Pliny, who was suffocated by sulphurous fumes or carbonic acid in the year 79. "Their fabrics are first imbued, not with dyes, but with dye-absorbing drugs, by which, though they seem to be unaltered, yet when immersed in a caldron of the boiling dye-liquor they are found to be painted. Yet, as there is only one color in the caldron, it is marvelous to see many colors imparted to the robe, in consequence of the influence of the pigment. Nor can the colors be washed out."

He farther remarks to the effect that a number of colors in the caldron would only give a neutral, blended, or confused effect; but, owing to the previous treatment, which made no visible stain, capacity was conferred upon the cloth for so appropriating the color, that different parts obtained different tinctures, according to a specific faculty for adoption and conversion due to the previous preparation in each case.

2. (*Gilding.*) A sticky substance to cause gold-leaf to adhere to an object.

Mo-reen'. (*Fabric.*) A watered woolen or wool-and-cotton goods, for hangings, curtains, upholstery, and heavy skirts.

Morn'ing-star. A weapon used in ancient times and as late as by the train-bands of London, in the time of Henry VIII. It consists of a ball with spikes, united by a chain to a staff.

Mo-roc'co. A fancy leather tanned with sumach and dyed. Used for bookbinding, ladies' shoes, upholstering furniture, cushions, etc.

The Saracens, on their expulsion from Spain, carried with them into Africa their art of preparing leather, and it is now named from the place to which the manufacture was then removed, — Morocco.

True morocco leather is prepared from goat-skins, but sheep-skins are extensively used in the preparation of an inferior quality. The coast of Barbary yet yields a large supply of goat-skins for the morocco-leather manufacturers of France and England.

For some centuries the principal supply was from the Levant, which still yields a large quantity of goat-skins and morocco leather.

The operations in the manufacture of morocco are substantially similar to those through which hides for upper leather are passed.

The *unhairing* process is followed by treatment in a tumbling cylinder in which the hides are agitated and beaten to remove some of the lime, and this is followed by *bating*, which neutralizes the remainder of the lime and renders the leather pliable.

The coloring, if red, precedes the tanning; dyeing with other colors follows tanning.

In dyeing red, two skins are sewed together by the edges, the flesh sides facing each other. The bag thus made is inflated with air, and the distended bag is dipped into the mordant and then into the dye.

The mordants and dyes are according to the color.

For red morocco, —

Mordant: alum or chloride of tin.

Dye: cochineal with or without saffron.

For morocco of other colors the skins are tanned previous to dyeing. They are placed in a revolving cylinder, with a warm solution of sumach. The process takes 24 hours, and the hide is then rinsed, dried, and dyed.

For dyeing, two skins are united by their edges, flesh sides in, so as to prevent the waste of dye by coloring both sides.

The dyes used are campeachy wood, indigo, or Prussian blue.

Quercitron for yellow.

Sesquiacetate of iron for black.

Blue and yellow baths in alternation for green.

Blue and cochineal for violets and purples.

Quercitron and cochineal for orange.

The dyed skins are pressed in a hydraulic press to remove superfluous dye-stuff, *beamed*, *dried*, *slicked*, *pommeled*, and *grained*.

The latter confers the peculiar appearance on the leather, and is done by hand or by machinery. The leather is indented by rollers which have raised parallel, straight, or diagonal threads, producing a wrinkled appearance.

See Muspratt's Chemistry, II. 530.

Morse Al'pha-bet. The telegraphic alphabet contrived by Professor Morse, and which has practically nearly superseded all others on land routes in the United States and on the continent of Europe, is composed of a series of dots and dashes. Though adapted for being instrumentally recorded on paper, it is usually read by sound, the receiving telegraphist writing down the words as they are transmitted.

Fig. 3225 is the Morse telegraph apparatus, with relay *a*; the invention of Professor Henry of the Smithsonian Institution. The key *b* being up, a current arriving by the line-wire *c* passes from *c* to *d*, thence through *e* to the coil of the relay *f*, and through this to the earth. The electro-magnet of the relay attracts an armature, whose contact completes the circuit through the local battery *g*, in which the coil that operates the armature *h*, constituting the indicator, is included. *i* shows that part of the appara-

Morse Apparatus and Alphabet.

tus by which the message may be impressed on a slip of paper, if required.

Mor'tar. 1. (*Grinding.*) A vessel, generally in the form of a bell or conical frustum, in which substances are pounded by a pestle. When large, they are made of cast-iron; a smaller size is made of bronze, and those for more delicate pharmaceutical operations are of marble, pottery, porphyry, or agate. They are used in connection with a pestle, which in the larger mortars is of iron and in the smaller is of porcelain or agate. The Wedgewood ware has long been a favorite for this purpose.

The difficulty is to find a material for mortar and pestle which will not scratch. Scratching is abrading, and adds a dust of the material of the mortar to the ingredients under treatment. This may be unimportant in many cases, but sometimes may fatally impair the chemical purity of the substance.

In the accompanying illustration, *c*, Fig. 3226, is from the tomb of Rameses III. at Thebes, and represents a man working in an Egyptian kitchen. The man is pounding something to be used in cooking.

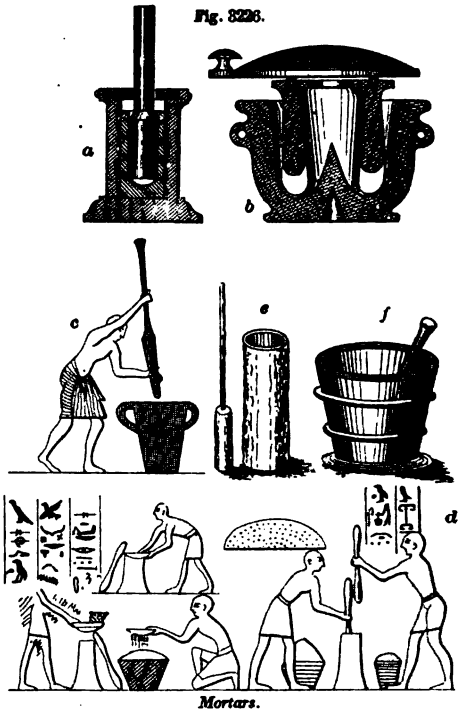
In ancient Egypt, as in modern, pounding substances in stone mortars in the public streets was and is an ordinary sight. The articles are brought to them by the inhabitants, and may consist of grain, salt, etc., which are pounded, sifted, and delivered. The figures *d* fairly represent the operation. One man appears to have a pan of the crude material in his hand and to be about to tip it into his mortar. In another place two men are using the pestles, giving alternate blows. Another man is sifting the stuff, whatever it is. Overhead is a piece of perforated metal which gives an indication of the nature of the process. The pestles are of metal, the mortars of granite, scooped out to about half its depth. The public practice of this industry is stated by Wilkinson to continue to this day.

The upward growth of the soil of Egypt by the deposits of the Nile has no doubt hidden thousands of these heavy tools, which were too heavy to move and had nothing in them to tempt the predatory bands by which that unfortunate country has been overrun at and since the time of Cambyses.

The mortar and pestle probably constitute the original appliance for grinding grain.

In many parts of the United States, and doubtless in foreign countries, remain many large, hollowed stones on which the grain of a community or tribe was pounded. Among the North American Indians the corn was reduced by this means to hominy or coarse meal, so as to be fit for making into cakes or mush. The present generation yet points to these stones in the neighborhood of the former sites of Indian villages. They are usually large surface stones of the bowlder type of rock, and probably had an incipient hollow, of which advantage was taken in forming the mortar.

Fig. 3226.



Mortars.

Besides this, or in place of it, some tribes had hollowed sections of tree-trunks, as among the Japanese of the present time. Throughout that country rice is *hummeled* in a wooden mortar.

Wedgewood ware appears to fulfill the requisitions for a good mortar better than any other substance, porphyry excepted. The great difficulty in working the latter has been a bar to their introduction. The French have made them as large as 29 inches in diameter.

A mortar should be able to resist scratching by steel, quartz, or flint. Should not be stained if sulphate of copper or muriate of iron be left in it for twenty-four hours. Should not be abraded by the rubbing down of an ounce of sharp sand to a fine powder. The pestle should possess the same character.

Mortars of iron, brass, marble, dolomite, and glass are acted on by particular solvents, especially acids.

Digitized by Google

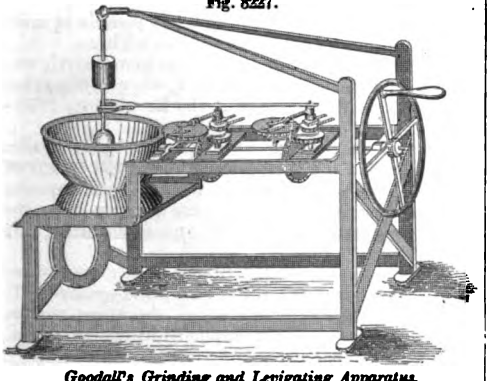
They are also too soft for many purposes. The color-mortar *b*, used in the porcelain manufactory of Sêvres, has a projecting conical piece in the center, which forms with the sides of the mortar a circular trough in which the pestle rotates. The pestle is a cylinder of porcelain, rounded at the bottom, and weighted with a disk of lead at the top, to which the handle is attached.

The colors are finished on a porphyry slab.

The mortar *a* for crushing diamonds for lapidaries' use is of hardened steel with a cylindrical cavity, and has a hardened steel pestle fitting neatly therein. The pestle is pounded with the hammer, being partially rotated between each blow. The diamond, though hard, is brittle, and is reduced to powder of the required fineness by this means.

A machine in which the pestle receives a motion similar to that imparted by hand is shown at Fig.

Fig. 3227.



Goodall's Grinding and Levigating Apparatus.

3227. As it traverses a different surface each rotation, no scrapers are required to keep the powder constantly under action.

A weighted lever secures the pestle at the top, and gearing from which it derives motion is driven by bevel gear from the main driving-shaft. The mortar is in front, to be out of the way of dust from the moving parts of the machinery. The pestle is attached to the driving-shaft by a screw, and may be removed when required.

B, Plate XXXV., ORE-MILLS, shows a form of mortar with a pestle traveling in a circular groove around a central post to whose horizontal arm the upper end of the inclined pestle axis is journaled. This block is of very hard stone, preferably porphyry, and has a grinding as well as a mashing action.

In the same plate is also a form of pulverizer known as the Chilian mill, having a stone traveling around its circular track and rotating on the horizontal axis rigged out from the vertical axis which is stepped into the middle of the table. See also CHILIAN MILL.

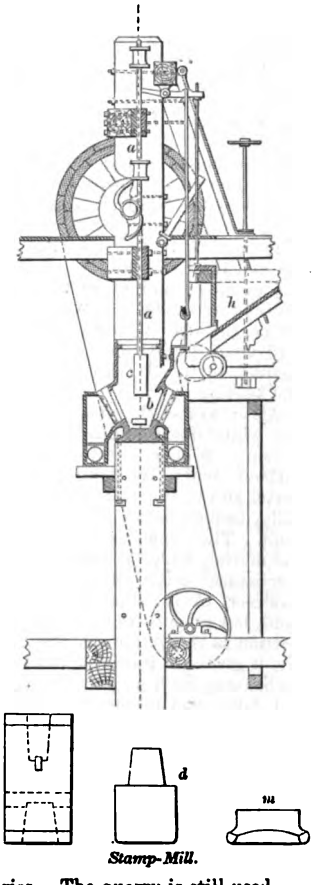
Fig. 3228 is a view of a stamp-mill for silver ores, in which *a* is the stamp-stem, *b* the mortar, *h* the hopper-car with the argentiferous rock, the feed being automatic by a tappet on the stamp-stem when the ore has become reduced to *slimes* and has floated off. The cut is a general view of the stamp, frame, and driving machinery.

Below are shown on a larger scale the *socket* or *stamp-head*; *d* is the *shoe*; *m* is the *die* which is placed in the bottom of the mortar. The shoe and die are removable.

2. (*Cement.*) A calcareous cement. It differs in its characteristics according to the nature, proportions, or treatment of its constituents.

The Romans are remarkable for their great use of calcareous cements, both the ordinary lime mortar and that mixed with volcanic matter from Puteoli, now Pozzuoli, from whence the name *pozzuolana*, commonly known as Roman cement. This material consists of porous, half-concreted volcanic matter, which is mixed with lime or common mortar to give it the property of hardening under water. It is mentioned by Vitruvius and Pliny.

Fig. 3228.



Stamp-Mill.

The use of lime in England, as we gather from the accounts of Julius Cæsar, was not known previous to the Roman conquest. The oldest limestone quarry in England was opened by the Romans at Tadcaster in Yorkshire, called Calcariæ in the Roman itineraries. The quarry is still used.

Lime most commonly occurs in the state of carbonate, such as marble, calcareous spar, oolite, limestone, or chalk.

Some limestones include in their composition so large a proportion of iron and clay as to enable them to form cements which have the property of hardening under water, and are called hydraulic limestones. The proportions of clay vary in different quarries, and often in the same from 8 to 25 per cent.

The pozzuolana consists of oxide of iron and burnt clay, and performs the same office as the clay in the above-cited limestones, acting with great energy in "setting" under water.

Limestone reduced to the finest powder is inefficient in the composition of mortar, but requires that the carbonic acid shall be eliminated by heat. This begins at the outside and proceeds to the center of the masses of stone. As the lime grows cold it commences to absorb carbonic acid, and, if time permit, will return to the state of carbonate.

When cold water is poured on a piece of well-burned lime, a large quantity is rapidly absorbed, the lime heats, exhales steam, and falls into dry powder. The weight of the lime is increased about 24 per cent, and it becomes a hydrate, or slaked lime. This hydrate is the ingredient in mortar. Carbonate of lime, as has been said, is not efficient in this connection.

Hydrate of lime may be made into a paste, but will powder or dissolve when dry. The admixture

Digitized by Google

of sand gives it the character of cement. The proportion of sand to lime, cited by Pliny, is round grained sand, 3; lime, 1; or sharp pit-sand, 4; lime, 1. He also recommends the use of pounded tiles. This is bringing in the clay element, cited above.

The common London mortar is sharp river sand, 2½; white chalk-lime, 1.

The cohesion of the two is due probably to something more than mere mechanical contact, as is proved by the fact that while a paste of chalk and sand is nearly as coherent as a mass of hydrate of lime and sand, the former will not harden into a cement and the latter will.

The moles and other marine structures of the Romans were cemented with a composition of lime, 1; pozzuolana, 2. Smeaton used, in building the Eddystone Lighthouse, hydrate hydraulic lime, 1; pozzuolana, 1. It was rendered plastic by continued beating.

Aiken states the general theory as follows: In the white limes or nearly pure carbonates of lime the only effect of burning them is to drive off the carbonic acid. By slaking, the lime becomes a hydrate, and in this state is capable of acting chemically, though feebly, on the surface of pure siliceous sand. This combination causes the first setting of the mortar, which is also strengthened by the mere mechanical action of the sand. The greater part, however, of the lime has not combined with the sand, but remains in the state of a hydrate. In proportion as this latter absorbs carbonic acid from the air, it gives out its water and passes to the state of carbonate; such mortar, therefore, acquires its final induration and dryness when the whole of the hydrate has been decomposed and the water has been replaced by carbonic acid. In losing 22 per cent of water it combines with 46 per cent of carbonic acid, and, therefore, the mortar becomes the more solid and strong.

In the blue limes, part of the calcareous matter combines during the burning with the silica, alumina, and oxide of iron constituting the intimately mixed ferruginous clay, forming a compound that gives to the cement made of it the property of setting speedily in the air or under water. The rest of the lime passes, by slaking, into the state of hydrate; and, if only siliceous sand is present, acts on it in the same manner that white lime does; but if ferruginous sand or burnt ferruginous clay be present, the hydrate acts more rapidly and powerfully on the clay, sooner gives out its water and consolidates. Whether this latter compound is afterward decomposable by exposure to the carbonic acid of the air, it is difficult to determine.

In those limes which contain naturally so much ferruginous clay as, after burning, to form cements without the addition of sand or other ingredient, the greater part of the lime is probably combined with the clay in the act of burning, a very small quantity of hydrate formed, and very little carbonic acid reabsorbed.

Dr. Artus's method of making mortar is to take well-slaked lime, 1 part, and mix carefully with it finely sifted sand, 3 parts; just before using add one quarter as much fine unslaked lime as there has been sand used, and mix thoroughly. While it is being mixed the mass heats and the silicates form through which it quickly stiffens and becomes very hard in a short time. This mortar resists all action of water, and can be used wherever durability is an object.

The Egyptian mortar, in some instances, was destitute of siliceous sand, its place being occupied by coarse powdered gypsum or native sulphate of lime.

Stone mortar. 8 parts cement, 3 parts lime, and 31 parts of sand.

Brick mortar. 8 parts cement, 3 parts lime, and 27 parts of sand.

Brown mortar. Lime, 1 part; sand, 2 parts; and a small quantity of hair.

Khorassar, or *Turkish mortar*, used for the construction of buildings requiring great solidity. ⅛ powdered brick and tiles, ⅜ fine sifted lime. Mix with water to the required consistency, and lay on layers of five and six inches in thickness between the courses of brick or stones.

3. (*Ordnance.*) A short gun with a large bore, used for throwing bombs. Said to have been used at the siege of Naples in 1435, and to have been first made in England in 1543. A colossal mortar constructed by Mallet was tried at Woolwich, October 19, 1857, with a charge of 70 pounds of powder, and it threw a shell weighing 2,550 pounds 1⅓ miles horizontally, and about ¾ a mile in hight.

Shells of 1,000 pounds are said to have been thrown into the citadel of Antwerp, 1832, when it was taken by the French in the war of the Revolution, 1830–32.

Mortars are constructed with a chamber of smaller diameter than the bore, for containing the charge of powder, which is poured in loose. Thin, tapering slips of wood, termed splints, are used for fixing the shell accurately in the bore, no sabot being employed.

Mortars in the United States service are divided into three classes, sea-coast, siege, and coehorn. To these may be nominally added the stone mortar, which is, however, only employed in regular sieges; none, we believe, were ever cast in this country. This and the Coehorn are of brass; the sea-coast and siege mortars of cast-iron. The two former classes are made upon the same general model, differing only in relative length and thickness of metal. The chambers of all are semi-ellipses, having their minor axes of the same diameter as the bore of the mortar.

The 13-inch sea-coast mortar (*a*) weighs 17,000 pounds, and its shell about 200 pounds.

The 10-inch light mortar (*b*) weighs about one ton, and throws a shell of 88 pounds.

The Coehorn (*c*) weighs 165 pounds, and its shell 24 pounds.

The length of bore of mortars seldom exceeds two or three calibers, and is often much less. They are intended for firing shells at high angles of elevation, generally 45°, the crushing and explosive power of their shells falling from great hights being relied on for destructive effect. They are principally used in sieges for destroying buildings, blowing up magazines, etc., and for keeping an enemy under cover within his bomb-proofs, reaching him where direct shots would fail to penetrate. Four sizes of iron mortars are used in the United States service, 8 and 10 inch "light" and 10 and 13 inch "heavy." The two former can be readily transported on wagons contrived for the purpose, and may accompany an army in the field; but the latter, in consequence of their great weight, are more particularly designed for permanent positions or for use on shipboard. The 13-inch was much employed in this way during the Rebellion, and on board the mortar-schooners fully demonstrated its efficiency, under favorable circumstances, in the operations against the forts below New Orleans. For firing, mortars are mounted on beds, at present made of wrought-iron in our service, resting on platforms of stout scantling and plank, no ordinary carriage being capable of resist-

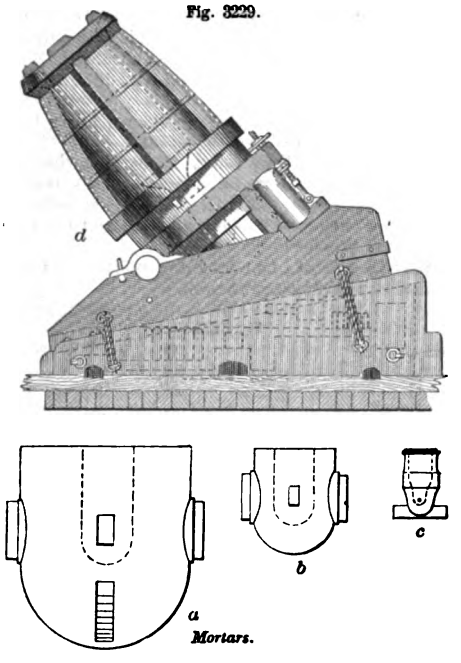
Digitized by Google

ing the immense downward shock of even a light mortar fired at a great angle with a full charge of powder.

Stone mortars are of large caliber, from 10 to 22 inches, and have a small chamber. They are light in proportion to their size, to admit of shifting from one part of a fortification to another, and are intended for firing baskets of stones at very short ranges, or, in place of stones, 6-pounder or other small spherical case-shot may be used. They are specially designed for use in the attack and defense of fortified places when the besiegers have succeeded in establishing themselves very close to the works. We are not aware of any instance of their employment in recent warfare.

Coehorns (*c*) are small mortars, likewise intended for attacking and defending fortifications. They are made light enough to be carried from one spot to another by hand as required, and generally carry a

Fig. 3229.



Mortars.

24-pounder shell with a maximum charge of ½ pound of powder, though they are sometimes smaller.

That employed in the United States service is of brass, 24-pounder caliber, and weighs about 160 pounds. It is mounted on a wooden bed, having four handles at its sides, by which it can be readily carried by four men. It derives its name from the celebrated Dutch engineer officer Coehorn, to whom the invention is attributed. See COEHORN.

In some European services much smaller mortars than these are recognized, weighing no more than 15½ pounds, and attached to a stock.

A small mortar of this kind was invented by Captain Goodwin of the United States service, and threw a shell with great effect in an experiment at the Washington Arsenal, 1864.

Coehorns are, owing to their lightness and portability, very efficacious in dislodging an enemy from covered positions.

During a war waged by the English against some of the Maori tribes of New Zealand, about the year 1843–44, one of the native chiefs with his forces intrenched himself in a "pah" or corral on the top of a hill, whence the means in the hands of the troops failed to dislodge him. In this emergency an engineer officer was dispatched to Sydney and caused twelve small mortars to be constructed, which effectually accomplished the desired object.

These were carried by men to within a few hundred feet of the "pah" to be attacked, and pitched their shells into the heart of the camp.

With a charge of 8 ounces of powder these mortars were found capable of throwing a 5-inch shell 550 yards.

The mortar, of gun-metal, weighed 65 pounds, and the bed, of cast-iron, 28 pounds; this was fixed on a piece of 2-inch plank, 24 × 16.

When loaded, the shell projected half-way beyond the muzzle of the piece.

The chase of Mallet's great mortar (*d*, Fig. 3229) is formed of short cylinders or compound rings; the chamber being of wrought-iron let into a huge mass of cast-iron. Each of the two lower rings is composed of seven rings, and each set of these again of three smaller rings rabbeted together; the top ring consists of five rings, each composed of three smaller rings rabbeted together.

There are two light rings acting as a sort of key-ring for the six bolts or staves, the bolt-head resting on the muzzle-ring and secured with steel collars in the cast-iron mass around the breech-piece.

The weight of the whole without bed is 42 tons.
Weight of bed, 8 tons.
Weight of shell, 24 cwt.
Caliber, 36 inches.
Charge of shell, 480 pounds of powder.
Cost of shell, charged, about £25.
Length of chamber, 2 feet 6 inches.
Bore at top of chamber, 18 inches.
Bore at bottom, 14 inches.
Length to top of chamber, 8 feet.

With a charge of 70 pounds of powder, a shell weighing 2,395 pounds was thrown 2,759 yards, burying itself eight yards in the ground on its fall.

The monster mortar employed by the French at Antwerp in 1832 had a total length of 4 feet 11 inches; its outside diameter was 39½ inches; caliber, 24½ inches; length from top of chamber, 27 inches; depth of chamber, 19 inches; diameter of chamber, 9 inches. The weight of the mortar was 14,700 pounds; that of the bed, 16,000 pounds; of the empty shell, 916 pounds; and the bursting-charge, 99 pounds.

The chamber would contain about 30 pounds of powder, but 12 pounds were found to project the shell to a distance of 800 or 900 yards.

This monster affair burst with a charge of less than 20 pounds of powder after a few rounds firing.

Among the largest mortars on record are those of the island of Malta. "The rocks here are not only scarped into fortifications, but likewise into fire-engines or artillery to defend those fortifications; being hollowed out in many places into the form of immense mortars. These mortars they fill with cantars of cannon-balls, shells, stones, and other deadly materials; and if an enemy's ship should approach with a design to land, they fire the whole into the air. The effect of this tremendous invention must be very great, as it will produce a shower for 200 or 300 yards around, and would make great havoc among a debarkation of boats. A cantar is about 100 pounds weight; and as the mouths of some of these mortars are 6 feet wide, they will throw, according to calculation, 100 cantars each." — *From an account written just before the submission of the island to General Buonaparte*, 1798.

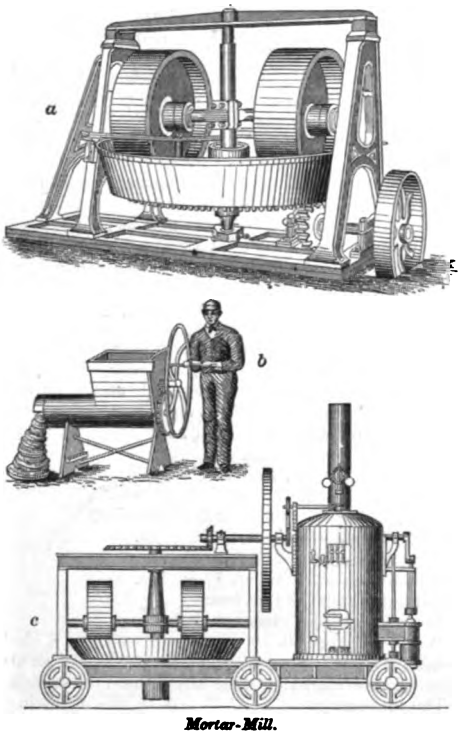
4. A short, thick candle.

Mor'tar-bed. The frame on which a mortar rests for firing.

Mor'tar-en'gine. A machine for grinding and combining materials into mortar. See MORTAR-MILL.

Mor'tar-mill. In the mortar-mill the sand, lime,

Fig. 3230.



Mortar-Mill.

and mortar are compounded together by rakes attached to the arms of a revolving wheel that moves round in a circular bed.

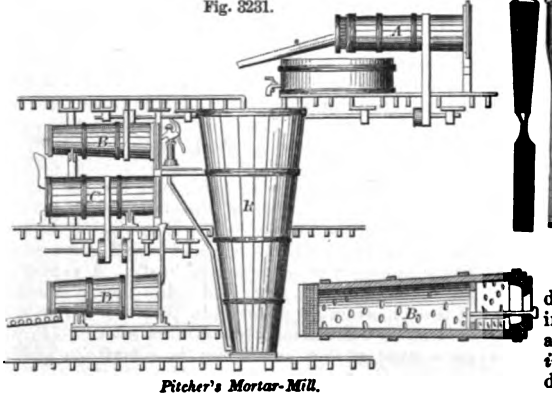
In the examples given, —

a is a large loam and mortar mill on the Chilian principle.

b is a mortar-tempering machine turned by hand-crank.

c is a mortar-mill on the same truck with the steam-engine which rotates the edge-stones in the bed.

Fig. 3231.



Pitcher's Mortar-Mill.

Fig. 3231 shows a mortar-mill on a large scale, occupying several floors of a building. The lime is slaked in a revolving barrel *A*, and discharged into a settling-vat. From this the "paste" passes to the curing-vat *R*, and is pumped thence into the upper one of three mixing-cylinders *B C D*. These revolving cylinders are slightly tapering, and have teeth on their inner surfaces, which mix the materials and gradually forward the mortar to the discharge end. It passes from one cylinder to another in the series, and from the lower cylinder *D* into the discharge-chute. The machine occupies three floors in a building.

Mor'tar-ves'sel. (*Vessel.*) A small vessel having a relatively wide beam for carrying a heavy mortar amidships. Formerly the vessel used was a *ketch*; hence, *bomb-ketch*.

Mor'tar-wag'on. A vehicle to transport a mortar and its bed.

Mor'tise. A cavity (*a b c d*, Fig. 3232) bored and cut into timber or other material to receive a *tenon*. It is the usual mode of joining the timbers of a frame, whether of a house or a machine.

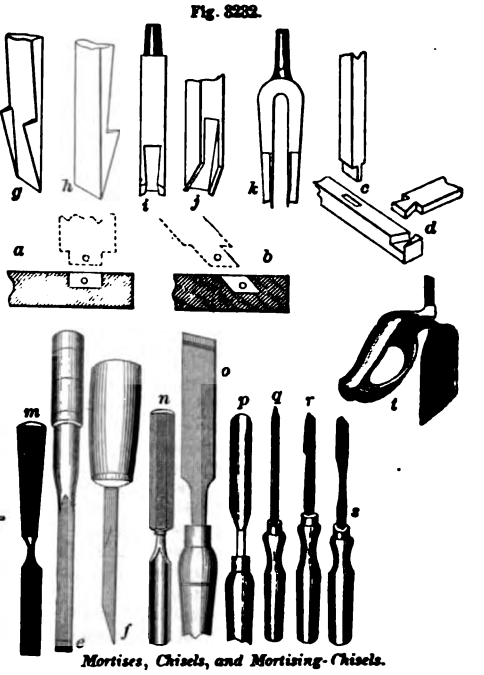
A lock made to slip in a mortise made in the edge of a door is a *mortise-lock*.

A wheel made with holes in its periphery to receive wooden cogs is a *mortise-wheel*.

Mortises in a hub are said to be *dodging* when they *dodge* in and out alternately, in order to spread the bases of the spokes and thus stiffen the wheel. The spokes are then said to be *staggered*, and the wheel is a *staggered* wheel.

Mor'tise-bolt. One let *into* a mortise in a door, instead of being placed *thereon*.

Fig. 3232.



Mortises, Chisels, and Mortising-Chisels.

Mor'tise-chis'el. A stout chisel (*e f*) driven by a mallet, and used to make mortises in framing. The smaller varieties have tangs, and the larger, sockets. The *firmer* and *turning* chisels, *m* to *s*, are introduced to show the difference. *t* is a hand-adze used in dressing

Digitized by Google

tenons. *g h* are two views of the chisel of the mortising-machine, having side-wings which cut the sides of the mortise a little in advance of the chisel edge. It is the invention of Brunel or Maudslay, being applied in the mortising-machine invented by the former and constructed by the latter in Portsmouth Dock-Yard, England, in 1802–8. (See Fig. 3240.) *i j* are mortising-machine chisels whose lips are so formed that the chisel, on being withdrawn, clears the mortise of the core or chips.

The chisel *k* is a double one, each limb having two lips, adapting the tool to cut a double mortise.

Mor'tise-gage. A scribing-gage with two sharp, adjustable points, which may be set to the distance for the mortise or tenon from the working-edge, and also the width of the mortise and size of tenon.

Mor'tise-joint. A joint made by a mortise and tenon.

Mor'tise-lock. (*Locksmithing.*) A lock adapted to be inserted into a mortise in the edge of the door, so as only to expose the *selvage* or edge-plate.

Mor'tise-lock Chis'el. A joiner's chisel for making the holes in door-stiles to hide the locks. It has a peculiar shape, in order to pull out the wood.

Mor'tise-wheel. A wheel having holes to receive wooden teeth, either on the edge or face, as the case may be. Such a tooth is specifically known as a *cog*.

Fig. 3233.

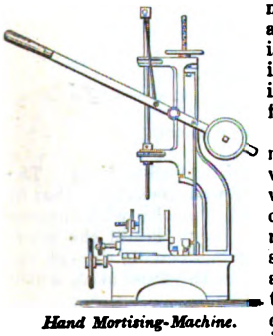
Mortise-Wheel.

Mor'tis-ing-ma-chine'. The self-acting mortising-machine was invented by General Bentham, and described in his specification of 1793. He made them for the British Admiralty previous to 1800.

His description includes the operation by means of a hole previously bored and then elongated by a vertically reciprocating chisel; and also the making of a mortise by a rotary cutter during the traveling of the work. One form included a pivoted table. He also invented double or forked mortise-chisels.

Fig. 3234 is a hand mortising-machine, having a vertically sliding bar carrying the cutter and moved by a counterbalanced lever. The work is clamped in the sliding table beneath, and is advanced by a hand-feed.

Fig. 3234.

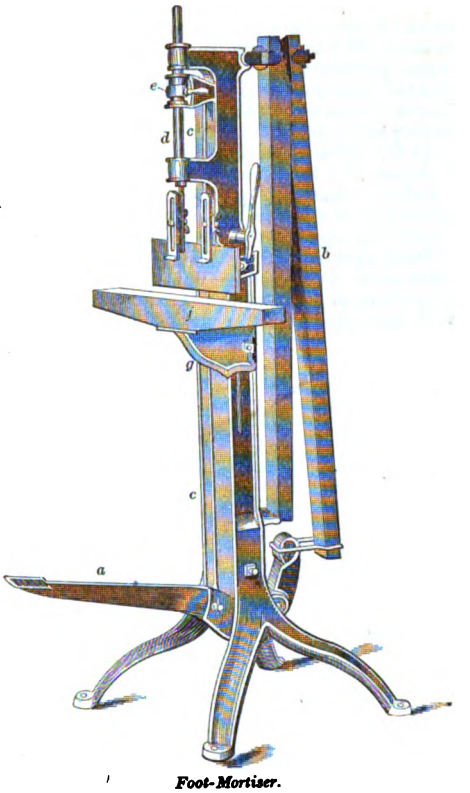


Hand Mortising-Machine.

Fig. 3235 is a foot mortising-machine, in which the treadle *a* works on a pin in the cross-brace, being connected to the wooden spring *b* by an iron strap at the back, and with the spindle *d* by the rod *c* in front; the chisel is held in a socket at the bottom end of the spindle, with which it is reversed by the handle *e* on the slide; the wooden rest *f* is screwed to an iron one *g*, which slides on the frame perpendicularly, and is secured to it by a bolt; the guide-plate is moved back and forward to adjust for the thickness of the stuff, and has stops to prevent the work from rising with the chisel.

In operating, the foot is pressed upon the treadle, which carries the chisel into the stuff to the required depth; when the pressure is relieved by raising the foot, it is withdrawn by the spring, and being lipped brings the chip out; after cutting far enough one way, reverse the chisel and finish the mortise to the required length.

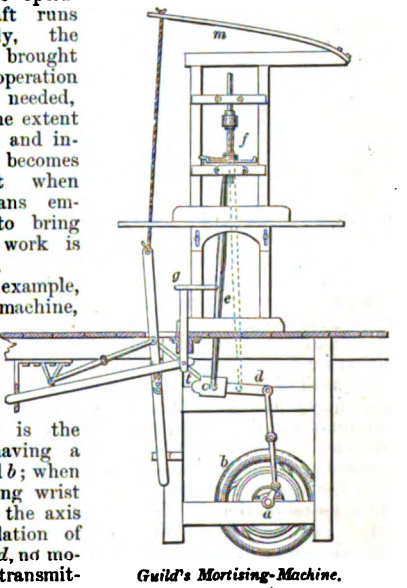
Fig. 3235.



Foot-Mortiser.

Fig. 3236 is an example of a form of mortising-machine in which, while the operative shaft runs constantly, the chisel is brought into operation when needed, and to the extent required, and instantly becomes quiescent when the means employed to bring it into work is removed.

Fig. 3236.



Guild's Mortising-Machine.

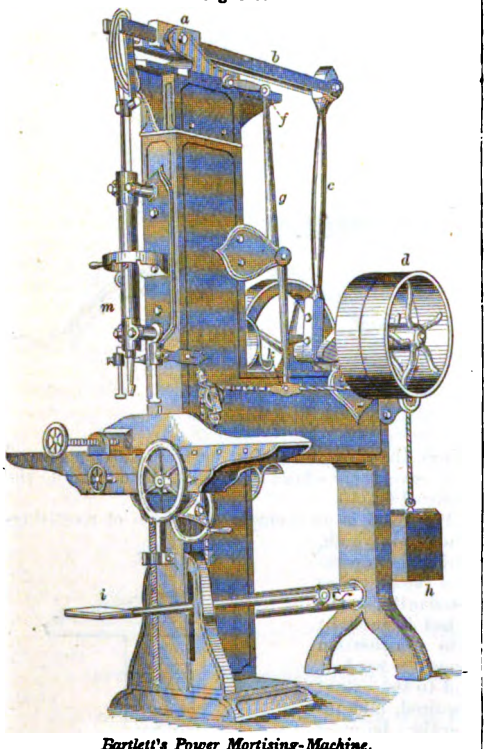
In the example, Guild's machine, 1852, *a* is the shaft, having a fly-wheel *b*; when the sliding wrist *c* is over the axis of oscillation of the arm *d*, no motion is transmit-

Digitized by Google

ted to the pitman *e*, which operates the chisel-stock *f*. When the treadle *g* is depressed, the sliding wrist *c* is driven out on the arm and partakes of its motion, the chisel being thereby reciprocated to a degree proportionate to the depression of the treadle, and the consequent distance of the wrist from its axis of oscillation. The spring *m* restores the wrist to its position of quiescence.

In Fig. 3237, the working parts are supported upon a strong iron frame, at the top or upper end of which are guides *a*, upon which is a slide having pivoted in it a collar through which is passed the lever *b* that operates the chisel-stock *m*. This lever is itself operated by a pitman *c* from a transverse crank-shaft at the rear end of the frame, and rotated by pulleys *d*. The slide is connected by a link *f* with the upper end of a vertical lever *g*, the lower

Fig. 3237.



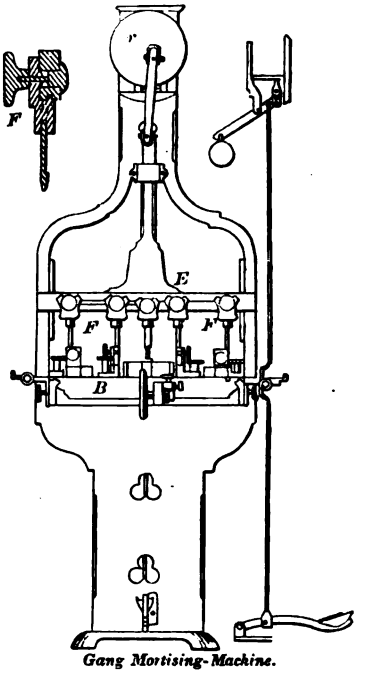
Bartlett's Power Mortising-Machine.

extremity of which is attached to a horizontal chain *k* passing over two supporting pulleys. The rear end of this chain has a weight *h* secured to it, and the forward end being passed downward is connected to a treadle *i* in such manner that by depressing the treadle the vertical lever will be caused to move the slide, and consequently the fulcrum of the chisel-operating lever, farther back, of course increasing the length of the forward arm of such lever, and consequently the stroke of the chisel-stock and its chisel. On releasing the treadle, the weight reverses the movement of the vertical lever, and throws the slide forward so that the stroke of the chisel-stock is reduced to almost nothing. By thus changing at will the fulcrum of the chisel-operating lever, the chisel may at any time be made to cut to any required depth, and when desired may be thrown out of operation, by the agency of the weight, without stopping the motion of the crank-shaft or interfering with the belt that drives the machine.

The table at the front of the machine for holding the stuff under the chisel is made compound, so that the stuff may either be moved along by hand or be held firmly upon the table and fed along as required by the hand-wheel operating the carriage or upper portion of the latter. The table is made adjustable vertically by means of a screw, and is pivoted and attached to its immediate supporting parts in such a way that it may be tilted, with one end or the other depressed to any desired angle, and there retained; the object of this being to enable the ends of the mortise to be cut at any required bevel or angle to suit the exigencies of various kinds of work.

Fig. 3238 is a gang mortising-machine. It has a set of chisel-holders *F F*, adjustable as to relative distance on a horizontal bar *E*, which is reciprocated by the wrist-wheel *r*. The work is clamped on the

Fig. 3238.



Gang Mortising-Machine.

bed *B*, which has the requisite feed-motions. The chisel-holders are provided with projections that fit in a slot in the cross-head, and also with tongues fitting into grooves on the lower side of the same. They are held in place by a bolt passing through the chisel-holders and the slot in the cross-head, which is secured by a thumb-screw.

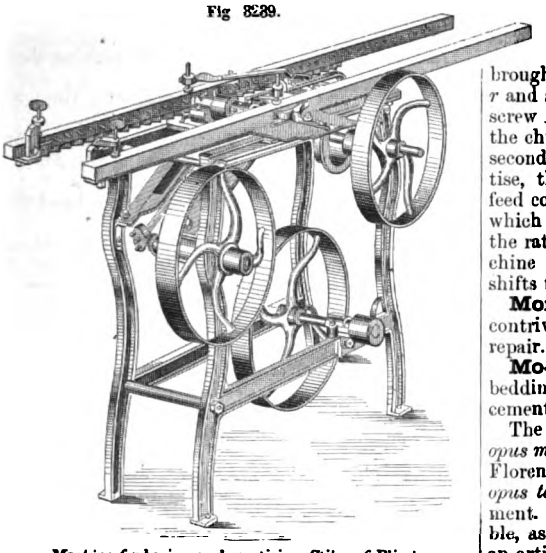
The mode of clamping the chisel-holders to the bar is shown in the smaller detached figure.

Buck's machine for boring and mortising the stiles of blinds is automatic in its operation, and either bores the round holes for the reception of the pivots of turning slats or mortises the recesses for the reception of the ends of those slats designed to be permanently fixed at a certain angle. The latter are made on this machine by means similar to those used in boring a simple round hole, the tool being a reciprocatory or traversing burr or bit, which can be used on knotty pine and other obstinate descriptions of wood where ordinary machine-chisels fail. The

Digitized by Google

machine is self-operating in all its parts. The workman puts in the stiles and sets the machine in motion, when it does its work, and, having done it, stops.

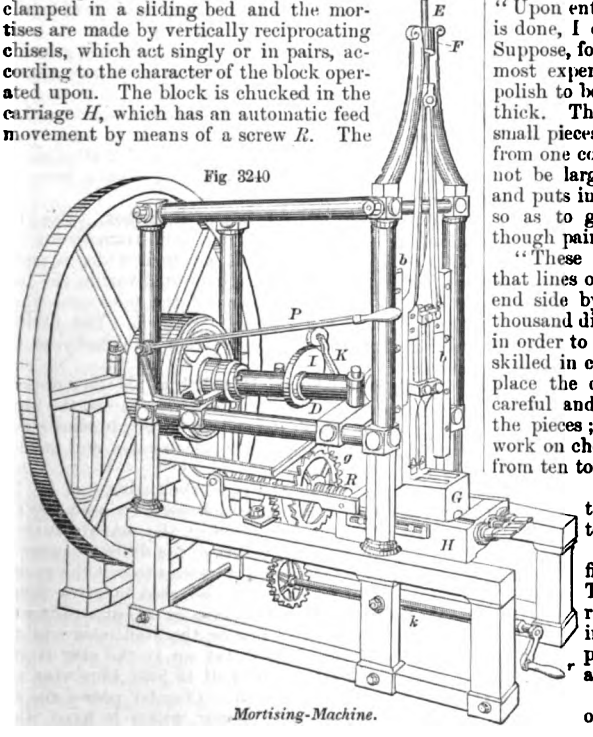
Fig 3239.



Machine for boring and mortising Stiles of Blinds.

Fig. 3240 shows Brunel's mortising-machine made by Maudslay for the British Admiralty, about 1804, for mortising the shells of ships' blocks. The series of machines for making blocks is described under BLOCK-MAKING MACHINE. In the mortising-machine represented, the blocks of wood are clamped in a sliding bed and the mortises are made by vertically reciprocating chisels, which act singly or in pairs, according to the character of the block operated upon. The block is chucked in the carriage *H*, which has an automatic feed movement by means of a screw *R*. The chisels are attached to a slider *E*, which reciprocates vertically in guides *b* and a socket *F* on the summit of the frame. The slider *E* is moved by a crank-arm which is connected thereto, and attached to the axis *D*, on which are the driving and fly wheels. In starting, the block is brought to the right position by turning the handle *r* and shaft *k*, which act upon the cog-wheel *g* and screw *R* to slide the carriage *H*. The first stroke of the chisel is into the hole previously bored, and the second takes a shaving in the direction of the mortise, the feed having commenced. The automatic feed consists of an eccentric *I* acting upon an arm *K* which turns the ratchet-wheel on the screw-shaft *R*; the ratchet is turned one tooth at a time. The machine is thrown into action by the lever *P*, which shifts the band from the loose to the fast pulley.

Fig 3240



Mortising-Machine.

Mor'ton's Slip. (*Hydraulic Engineering.*) A contrivance for hauling ships out of the water for repair. Patented in England, 1819. See SLIP.

Mo-sa'ic. 1. Ornamental work produced by imbedding different colored stones, glass, or gems in a cement.

The simplest form is the dice-shaped pavement, or *opus musivum*, of the Romans. The *pietra dura*, or Florentine work, is an amplification of the idea. The *opus tesselatum* was a tesselated geometrical pavement. The *opus sectile* was formed of slices of marble, as its name implies. The *opus vermiculatum* is an artistic rendering of the forms, lights, shades, and colors of pictures by the selection, shaping, and apposition of pieces of stone or gems of the right color.

A traveler in Italy relates that he saw a Florentine mosaic table valued at two hundred thousand dollars. It was less than six feet in diameter, but had required the work of a large number of men for fifteen years. It was ornamented with mosaic work composed of stones of different colors and shades matched together so as to form pictures. The traveler says: "Upon entering the hall where this kind of work is done, I could not doubt these enormous figures. Suppose, for instance, a thousand of the hardest and most expensive stones which will take on a high polish to be cut into pieces three eighths of an inch thick. These pieces are cut the other way into small pieces like shoe-pegs, and where the shading from one color to another is sudden, these pegs must not be larger than a needle. Now the artist cuts and puts in these, selected according to their color, so as to give the coloring wanted as distinct as though painted.

"These pieces or pegs must be fitted so closely that lines of separation will not show, and set upon end side by side like types. They claim that ten thousand different shades of color are necessary; and in order to do this kind of work a man must be as skilled in colors and shades as a painter, in order to place the colors properly, and then be the most careful and accurate of mechanics, in order to fit the pieces; and he must have patience enough to work on cheap pictures one year and on a fine one from ten to twenty years."

Some wonderful specimens of mosaic are to be seen at the Imperial works, St. Petersburg, Russia.

Roman mosaic consists of pieces of artificial enamel, in place of natural stone. The enamel is drawn out into rods of various sizes, cut into lengths, and arranged in cases something after the manner of printing type, the boxes containing each a different shade or color.

Glass mosaic is made of rods, shreds, or *hairs* of glass enamels of various colors

Digitized by Google

arranged side by side, so that their ends show the pattern. The bundle of glass rods, being cemented by heat, may be cut across, and each section show the pattern. *Filigree glass* and millefiore are of this character. Some of the ancient Egyptian beads were thus made.

The Tunbridge *wood-mosaic* of England is made of colored parallelopipeds of wood glued together so as to show a pattern at their ends or sections.

Mosaic rug-work is made by a careful selection of colored wools, which are stretched in a frame, so that a cross-section at any point will show the design. About 800,000 threads are thus held in a cast-iron box with a movable bottom. The top surface, formed by the ends of the threads, is treated with a solution of caoutchouc, and a backing of canvas similarly treated is laid upon it. The bundle of threads is then pushed up in the box by screwing up the false bottom $\frac{3}{16}$ of an inch. A section of the threads at this depth is then made by a horizontally revolving knife, and the sections of thread come off on the backing, to which they adhere, forming a nap thereon.

2. A pyrotechnic device consisting of a surface with diamond-shaped compartments, formed by two series of parallel lines crossing each other. The effect is produced by placing at each intersection four jets of fire which run into the adjoining ones. The intervals between the jets must be associated with the discharge of others, so as to keep up a succession of fires in the spaces.

Mo-sa'ic Floor. One laid in colored woods, tiles, or marbles, systematically arranged, either symmetrically or pictorially.

Mo-sa'ic Glass. Mosaic glass is formed by the association of various colored opaque or transparent rods of glass, so arranged that the ends may form patterns.

Sections being removed, the pieces are arranged for the production of a recurring pattern, or a general combination is formed by the association of a variety of separate ornaments.

A section imbedded in a bulb of transparent glass forms the *millefiore* paper-weight.

The *aggry-beads* of Ashantee are of this class, and show that at some former time the country was visited by, or had communication with, a land where glass-making was artistically practiced.

Another form of glass mosaic consists in the putting together of pieces of glass enamel of varying colors, and sawing them into rectangular prisms. See GLASS MOSAIC.

The art of glass-making, instead of being comparatively modern in the time of Pliny, had long been practiced in Egypt. The manner in which the mosaic glass was made is thus described by Dr. Abbott, referring to specimens in his collection now in the Museum of the Historical Society, New York City.

"678. Three fragments of colored glass on a card.

"No. 1 represents a star, No. 2 a lotus. These pieces are particularly interesting as examples of a curious manufacture. No. 3 more especially deserves attention, inasmuch as it explains the ingenious manner by which the ancients accomplished the work. Long sticks of glass of the desired color and form were welded together, side by side. This mass, being well united, was then sawn through transversely at regular intervals, thus producing a supply of perfectly similar patterns. The pieces thus obtained were afterward polished and inserted, like mosaic work, to decorate various utensils. Thus, for example, were produced a series of stars of exactly similar dimensions and form as No. 1, which were inserted side by side in a cavity to represent the heavens; or the ornament No. 2, representing the lotus, was thus reproduced with an exactness which no other contrivance could guarantee. The piece No. 3 has evidently been sawn from such a stick of glass as above described and broken off. They were found at Sakkarah."

Mo-sa'ic Gold. A brass used for making cheap jewelry.

Hamilton and Parker's: copper, 32; zinc, 33. Or, copper, 4; zinc, 1.

Hermstadt's: copper, 7.; zinc, 1; platinum, 16. Resembles gold in color and weight. See ALLOY; MOCK GOLD.

Mo-sa'ic Pave'ment. One laid in colored tiles or slabs arranged in systematic order.

Mo-sa'ic Tile. A tile molded with different colored clays, arranged in patterns in imitation of the associated pieces of colored stones in a true mosaic.

Mo-sa'ic Wool. A form of rug or mat made from colored wool, arranged so that the ends of the wool present a definite pattern.

Threads of wool of equal length are placed horizontally in a frame, close together, to form a compact mass. They are of different colors, and the colors are arranged in conformity with a pattern. The threads, being held firmly in the frame, are then cut across to form cubical masses, all the threads in each cube being kept rigidly in their places. The cube is then placed in a frame with the threads vertical, and a clean cut made across the top. The smooth surface is then wetted with a solution of rubber, and a piece of canvas firmly attached. When dry, a machine cuts off a slice of such thickness as is desired for the length of the pile. A rug or mat of a velvety finish is thus produced. Other slices can be cut off in the same way until the wool is exhausted.

Mo'ses-seam. A sailmaker's seam, as the selvages of the canvas lap past each other. See MONK-SEAM.

Mos'lings. The thin shreds or scrapings of leather shaved off by the currier in dressing skins.

They are used in wiping off metals while grinding and polishing. Cotton waste is used in a similar manner when plentiful.

Moth'er-gate. A lateral passage where a shaft intersects a seam of coal.

Moth'er-lye. The liquid remaining after all the salts that will regularly crystallize have been extracted from a solution.

Moth'er-of-pearl Mi-crom'e-ter. The micrometer of Cavallo. A thin semi-transparent slip of mother-of-pearl, $\frac{1}{10}$ of an inch wide, is ruled with fine graduations, and mounted within the tube at the focus of the eye-lens of the telescope, where the image of the object is formed. The divided edge is brought into convenient proximity to the image.

Moth'er-of-pearl Work'ing. Mother-of-pearl is the inner coat or layer of some sea-shells, the beautiful tints of which depend upon the lamellar structure of the surface, which decomposes and reflects the light.

The structure of the pearl shell admits of its being split into laminæ, which may be used for the handles of knives, for inlaying, the manufacture of buttons, etc.; but in practice, the different parts of the shell are selected of a thickness to suit the special purposes, and the pieces are adapted by saws, filing, or by the grindstone. Square or angular pieces are cut with the circular saw or the back saw; in the former case, the shell is fed up as the saw divides it, and in the other the shell is held in a vise and the saw operated by hand. Circular pieces are cut with an annular or crown saw, which is fixed upon

Digitized by Google

a mandrel. In sawing and grinding, water is plentifully supplied to the instrument.

After the pieces of pearl shell are cut, ground, or turned to the proper form, they are finished with pumice-stone and water, while the work is held fast in a form of clamp as it is revolved in a lathe. This process may be followed by an application of ground pumice-stone applied with a piece of cork or a cloth moistened with water. The polishing is with rotten-stone, powdered chalk, or Spanish whiting, moistened with dilute sulphuric acid, which may be applied upon a piece of cork or a bit of soft wood. The acid tends to develop finely the striated structure of the shell. In some turned works fine emery-paper may be used, and followed with rotten-stone moistened with the acid, or some limpid oil instead.

The grinding or polishing material may be applied to the surface of wheels covered with cloth and moistened with water, the pumice-stone, and the rotten-stone. Sometimes dry powdered chalk or Spanish whiting is used in the place of the rotten-stone.

Pearl may be engraved in relief, by the aid of corrosive acids and the etching-point. The designs or patterns are drawn upon the shell with asphaltum varnish; strong nitric acid is then brushed over the plates repeatedly, until the parts undefended by the varnish are sufficiently eaten away by the acid. The varnish being washed off with turpentine, the device, which the acid has not touched, is found in relief.

Moth-trap. An attachment to a beehive to catch the moth, — *miller*, as it is familiarly called, — whose larva builds its web in the hive, and destroys the colony.

Some traps have slats, with intervals which are adapted for the passage of the moth, but too small for the bees. The moth runs in here for concealment, and hence their eggs are taken and destroyed. Other traps are on the principle of the *cul-de-sac*, and are removable for the destruction of the tenants. Others have a liquid in which the moth or larvæ are drowned.

Mo'tion. 1. The train of wheels in a watch immediately concerned in the moving of the hands. See MOVEMENT.

2. (*Steam-engine.*) *a.* The cross-head in a locomotive.

b. The slide, slide-rod, and link of a locomotive-engine.

Mo'tion-bars. (*Steam-engine.*) Guide bars or rods.

Mo'tor. Properly speaking, — a source of motion, such as heat derived from the combustion of coal used in expanding a substance such as water or air; falling water; air in motion; dynamic electricity produced by chemical reactions or otherwise; animal strength, etc.

Technically, — a prime mover in the sense of a steam, air, or electro-magnetic machine; a water-wheel, horse-power, etc. See under those heads.

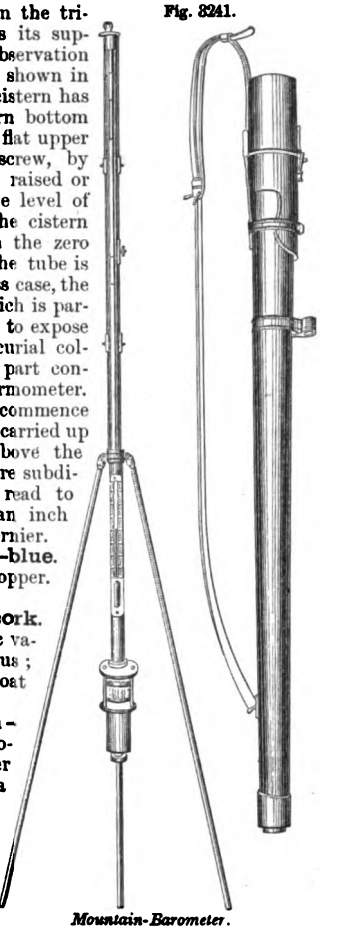
Moulde'baert. The Flemish earth-scraper. A large shovel drawn by a horse and guided by a man. A *grading-scraper*.

Mou'line; Mou'li-net. The rope-winding drum of a hoisting-machine.

Mound. (*Civil Engineering.*) A lump of original ground left at intervals to show the depth of ground excavated.

Moun'tain-ba-rom'e-ter. A portable barometer designed for measuring vertical hights above the sea. It is, consequently, more carefully made and accurately adjusted than the common barometer. That of Troughton, which is most generally known and probably the most convenient, is, for transportation, inclosed in the tripod which forms its support when an observation is to be made, as shown in Fig. 3241. The cistern has a flexible leathern bottom resting upon the flat upper extremity of a screw, by which it may be raised or lowered until the level of the mercury in the cistern corresponds with the zero of the scale. The tube is inclosed in a brass case, the upper part of which is partially open, so as to expose to view the mercurial column, the lower part containing a thermometer. The graduations commence at 15 inches, are carried up to 33 inches, above the zero point, and are subdivided so as to read to thousandths of an inch by means of a vernier.

Fig. 3241.



Mountain-Barometer.

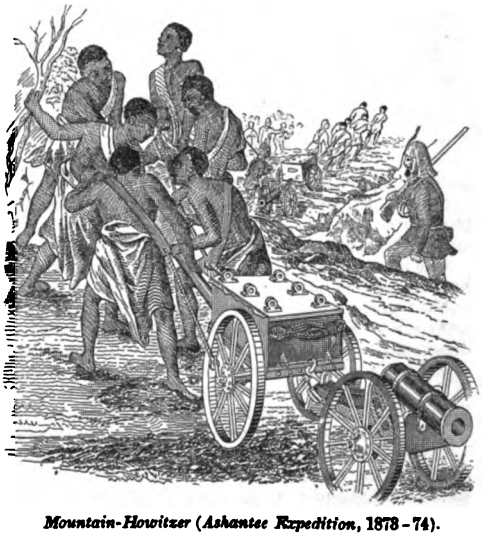
Moun'tain-blue. Carbonate of copper. Malachite.

Moun'tain-cork. A spongy, elastic variety of asbestus; light enough to float in water.

Moun'tain-green. A carbonate of copper combined with a white earth.

Moun'tain-how'it-zer. A light field-piece, of large caliber in proportion to its weight. It is mounted on a light carriage which may be drawn by one horse.

Fig. 3242.



Mountain-Howitzer (Ashantee Expedition, 1873-74).

Digitized by Google

The howitzer and its carriage may each be packed on the back of a horse or mule.

The piece shown in the cut is a gun of the howitzer battery made for the negro contingent in the Ashantee war, just concluded. Sir Garnet Wolseley's dash on Coomassie is something of which to be proud.

Moun'tain-leath'er. A variety of leather with interlacing fibers producing a texture resembling leather.

Moun'tain-lime'stone. A series of marine limestone strata, below the coal measures and above the old red sandstones.

Mount'ing. 1. The setting of a gem.

2. The frame of a picture.

3. The back stiffening or support of a print or map.

4. The harness tackle of a loom.

5. The carriage and tackle of a piece of ordnance.

6. The ornamentation of the stock of a fowling-piece.

7. The fastening of a piece to be turned on the mandrel of a lathe.

8. (*Saddlery.*) In the plural, — a general term given to the metallic trimmings of harness. In England called harness furniture.

Mouse. 1. (*Nautical.*) *a.* A ball, knob, or puddening worked on a rope.

b. A turn or two of spun-yarn uniting the point of a hook to the shank to prevent its unhooking.

2. (*Blasting.*) A match used in firing guns or mines.

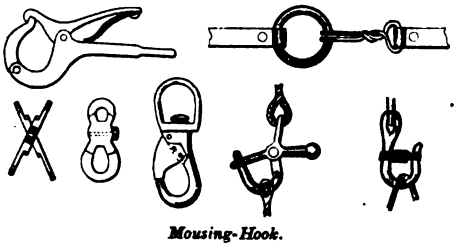
Mouse-trap. A small trap for catching mice. (See ANIMAL TRAP.) Pepys in his Diary, 1661, mentions purchasing two mouse-traps on his way home.

Mous'ing. 1. (*Loom.*) A ratchet movement in a loom.

2. (*Nautical.*) A lashing or latch connecting the bill with the shank of a hook.

Mous'ing-hook. A hook secured by a mousing passing around its two branches and closing its

Fig. 3243.



Mousing-Hook.

mouth, in order to prevent it from straightening out when supporting a heavy weight or to obviate the danger of unshipping.

Fig. 3243 shows several forms: —

One has a mousing of cord, by which the bill of the hook is secured to the shank.

Next to it is one with a retaining and releasing hook.

Above is a pair of hooks engaging in different directions, one forming a mousing for the other. *Sister-hooks.* A snap-hook.

On the left, below, are views of a watch-chain or brequet hook, having portions which open on a swivel.

Also a hook having a mousing-block of caoutchouc.

Above is a gravitating mousing-link which throws off from the point when the load on the hook is suddenly lightened, as in the case of the hooks of davit-fall blocks.

Mousse-line'. French muslin.

Mouth. 1. An opening by which a vessel is filled or emptied; if it have a turned-over edge, such is called a *lip.*

2. The muzzle of a fire-arm.

3. The opening of a vice between its *chops, chaps, cheeks,* or *jaws,* as they are indifferently termed.

4. (*Metallurgy.*) *a.* The charging opening of a furnace.

b. The hole in a furnace out of which melted metal flows.

5. The cross-bar of a bridle-bit; uniting the branches or the rings, as the case may be.

The *mouth* gives character to the bit as the *straight* mouth-piece, or *arched, severe, jointed, wired, clothed,* or *with rollers,* as the case may be.

6. (*Music.*) *a.* The opening in an organ pipe whence the wind emerges. Being directed against the *lip* or *wind-cutter,* it acquires a vibration which is imparted to the column of air in the pipe, producing a musical sound. The principle of the flageolet is similar.

b. In a flute, — the edge of the opening against which the air from the mouth of the performer is cut, the vibration thereby imparted being communicated to the column of air in the tube. The *pitch* depends upon the length of the tube beyond the mouth, and the holes allow the length to be varied so as to produce varying notes. See PIPE.

7. (*Fortification.*) *a.* The outer or widest part of an embrasure. The narrow part is the *neck.*

b. The part of a trench most remote from the besieged place.

8. (*Joinery.*) The slot in a plane to receive the bit.

Mouth-gage. (*Saddlery.*) A device for measuring a horse's mouth, consisting of a gage which answers as the mouth-piece, a stationary cheek-piece on one end, and a sliding cheek on the other, with a set screw to hold it in any desired position. On the lower arm of the sliding cheek there is another slide held to its place by a set screw. The first slide is used to obtain the exact width of the horse's mouth; the slide on the lower arm of the sliding cheek is used to measure the hight of the bar of the mouth, each of the bars being gaged in inches and fractions.

Mouth-glass. (*Dentistry.*) A dentist's small mirror for inspecting the teeth and gums.

Mouth-piece. (*Music.*) 1. The part of a wind-instrument applied to the lips.

2. (*Saddlery.*) That part of the bit which is placed in the horse's mouth.

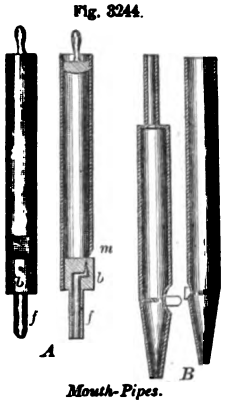
Mouth-pipe. (*Music.*) *a.* The part of a musical wind-instrument to which the mouth is applied.

b. An organ pipe having a lip to cut the wind escaping through an aperture in a diaphragm. See FLUTE-ORGAN.

The *mouth-pipe* is similar to the *flageolet.* In the *wooden* mouth-pipe *A* of the organ it is a cylinder or a parallelogram; in the latter case, the inside sectional dimensions are as 4 to 5, the interior surface being smoothed by an application of size. The pitch of the note depends upon the length of the pipe above the mouth. The upper end may be open, or stopped by a *tampion,* which fits air-tight. The lower end is closed by a block on which three of the walls of the pipe are glued. The front wall terminates in a sharply beveled edge at the lower end, just above the block *b,* the space forming the mouth *m,* and the edge itself the *lip* or *wind-cutter.* The wind-pipe *f* from the bellows is attached to the block *b.* A block is fastened to the walls of the pipe, leaving an intervening space between which the wind passes

Digitized by Google

Fig. 3244.



Mouth-Pipes.

to the mouth. The aperture is called the *plate of wind*, and the sheet of air issuing therefrom is cut by the sharp edge or lip at the lower end of the front wall, the vibrations caused thereby being communicated to the column of air in the tube and producing a musical note. See PIPE.

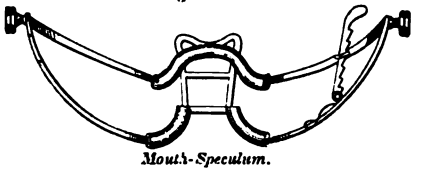
The *metallic* mouth-pipe *B* differs from the wooden one, not alone in the material, but in the construction. The lower end is diminished so as to meet the size of the pipe which conducts the wind from the bellows, and at a point opposite the *mouth*, or slit in the front of the tube, a *languette*, or plate, is placed, nearly closing the interior area of the pipe. Between the *languette* and the under lip a *plate of wind* is formed, the stream of air from which impinges upon the upper lip, and the vibration thus imparted is communicated to the column of air in the pipe.

At each end of the slit or mouth is a soft-metal lug which is called an ear, and is bent more or less over the mouth to modify and qualify the tone.

One of the figures shows a pipe at whose upper end is a smaller, open pipe; this is termed the *chimney-top*, and the partial opening thus afforded has the effect of *sharping* the note. The same effect in kind, if not in degree, is attained by making a hole in the *tompion*.

Mouth-spec'u-lum. (*Surgical.*) *a.* An instrument for depressing the tongue and raising the soft palate to expose the posterior fauces.

Fig. 3245.



Mouth-Speculum.

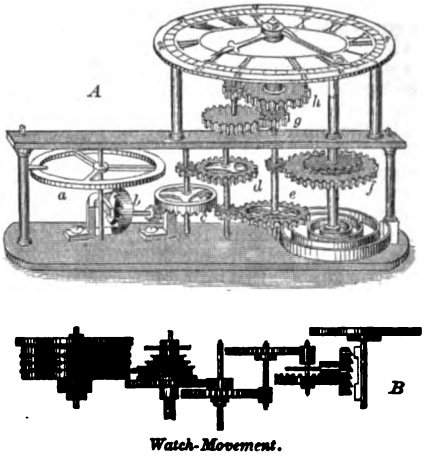
b. A frame to keep the jaws apart while operating in the mouth.

Mov'a-ble Lad'der. A form of *man-engine* for ascending and descending shafts. See MAN-ENGINE.

Move'ment. (*Horology.*) The going mechanism of a watch or clock. The motor, train, regulator, and indicator of time.

In Fig. 3246, *A* is a view of a watch-movement with vertical escapement, the barrel containing the mainspring and the fusee being removed. *B* is an elevation of a movement, barrel and fusee in place. In the lower right-hand corner (upper figure) is the mainspring, one end of which is fast to a pillar and the other to the winding-stem, which carries a ratchet-wheel provided with a click, and also the spur-wheel *f*. When the watch is wound up, the spring is condensed, and through the medium of the click operates to rotate the winding-stem, the wheel *f* on which turns a pinion and through it the wheel *e*, which gears with a pinion, causing the movement of the wheel *d*, rotating a pinion on the shaft of the crown-wheel *c*, which turns the pinion of the scape-wheel *b*. The teeth of this are alternately engaged by and released from two pallets on the axis or *verge* of the balance-wheel *a*, causing it to oscillate back and forth to an amount determined by a stop, so as to perform a uniform number of oscillations in a given time, thus regulating the movement of the works. The shaft of the wheel *e* is prolonged upwardly, and, passing through the hollow shaft of the wheel *h*, carries the minute-hand at its

Fig. 3246.



Watch-Movement.

upper end. It also carries a pinion *g*, which engages a wheel on an upright shaft, turning a pinion which gears with the wheel *h* on the hollow shaft that carries the hour-hand. The number of teeth in the various wheels and pinions bear such relations to each other, that when the balance-wheel and escapement are in adjustment, the minute-hand shall be carried around the dial in exactly one hour, while the hollow shaft of the wheel *h* rotates but $\frac{1}{12}$ as fast, carrying the hour-hand round but once in 12 hours.

Mow. (*Husbandry.*) A bay or large compartment of a barn in which hay or sheaves of grain are stored ready for thrashing.

Mow'er. (*Husbandry.*) A machine for cutting grain or clover. A great many devices were used before a satisfactory conclusion was reached. Plate XXX. shows a large number of distinct inventions, involving reciprocating and circular movements of single knives and knives working in apposition. The illustrations and group headings will be readily understood, and the dates will add interest to the list, showing the length of time that man has been hammering at the problem. The harvester used in the plains of Rhætia, in the time of Pliny, had no proper motion, but was simply a comb whose teeth had sharp edges which cut and tore the head of the grain from the stalk and allowed it to be brushed into the box of the machine. See REAPER; CLOVER-HARVESTER.

Mowing was a familiar duty in Palestine, and the Scripture references to it show that the ardent sun cured the grass in a short time, as with us. The sudden wilting and quick drying which form the basis of so many beautiful comparisons in the Bible are more descriptive of the Syrian or American hay harvest than that of England, where persistent spreadings and turnings are the order of the day.

Moses and David use the similitude: —

"In the morning it flourisheth and groweth up; in the evening it is cut down and withereth."

"For we are *consumed* by thine anger."

Digitized by Google

"My heart is *smitten*, and withereth like grass."

The uses of hay in Palestine are nearly forgotten. The *tibn* of the Arabs, the ordinary fodder for cattle and horses, consists of straw. It is sometimes cut and mixed with barley. Chaff, or the husks of grain, is also used.

The most ordinary classification of mowers is the apparent one, *two-wheeled* or *one-wheeled*. The former of these is shown in Figs. 5, 8, 9, 11, 14, 16, of Plates XXXI., XXXII.

A one-wheeled mower is shown at Fig. 1, Plate XXXI.

Another distinction is the mode of attaching the finger-bar to the frame, *rigidly* or by a *hinge*. The former of these is shown in Figs. 1, 2, 3, 4, Plate XXXI., the different figures having distinguishing features. Figs. 5 to 12 inclusive show various adaptations of the hinged finger-bar.

Another distinction common among those who use the machine is the position of the cutter-bar in point of degree of advancement relatively to the driving-wheels. These positions are known as *front-cut*, *center-cut*, *rear-cut*; that is, before the driving-wheel, even with the axle, rearward of the driving-wheel. The first is shown in Figs. 2, 5, 9, 10, 11, 15, 16, 21, of Plates XXXI., XXXII., XXXIII.; the second in Figs. 1 and 7, Plate XXXI.; the last in Figs. 4, 6, 8, 13, 19, of Plates XXXI., XXXII.

Several modes of draft also furnish peculiarities worthy of notice. The *center-draft*, as in Wilber's patent, in which the cutter-bar stretches across the width of the driving-gear. The *side-draft*, in which the cutter-bar projects laterally, so that the horses walk in the swath previously cut, not tramping in the standing grass. This feature is shown in most of the figures in the Plates. One other mode of draft

Fig. 3247.

Steam Mowing-Machine.

is to be noticed, and that is the *propeller*, in which the cutting apparatus is ahead of the horses, which push the implement before them. This is the original form, it may be presumed, and was used in Gaul eighteen centuries since (see figure under the subject REAPER). The form still survives in the CLOVER-HEADER (which see). Reapers have other features, such as *reels*, *rakes*, *droppers*, etc., and are considered under REAPER.

Digitized by Google

In Fig. 3247 a steam-engine is shown as adapted to operating the implement.

In some parts of Solano County, California, where the grain and grass are very short, an apron is fitted under the sickle of the mower, which catches all the grass, and when full dumps it in piles. Grass and grain not over three inches in hight are thus secured, in some cases at the rate of a ton to an acre.

The smallest description of mower is that for mowing lawns, which is pushed by the gardener so as to cut the grass before it is tramped.

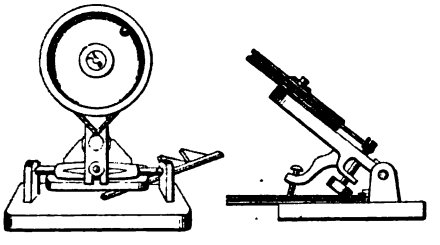
It weighs about 30 pounds and cuts a swath of 10 inches. The cylinder has spiral knives, and is rotated by gear connection to the wheels of the machine. These spiral blades cut against the rectilinear edge of a stationary knife, which is set at a tangent to the cylinder. The grass is nipped between the blades and swept into a trough in the rear, which carries it until sufficient has accumulated to render it advisable to empty. The grass is kept short by frequent cuttings. See LAWN-MOWER.

The classification just given concerns many parts common to *mowers* and to *reapers*, which are included under the generic title *harvesters;* the latter also embraces many other machines for cutting crops, such as beans, corn, cotton, hemp, etc. For a list, see HARVESTER.

The features appertaining to grain-harvesters proper, such as rakes, reels, droppers, binders, etc., are classified and considered under REAPER (which see).

Mow'ing-ma-chine' Cut'ter Grind'er. A grindstone or emery-wheel arranged and adapted for grinding the knives of mowing-machines. The example is a portable implement to be placed on a bench or stool. The cutter-bar is clamped to the base-plate, being guided to position by the angular projection on the adjustable bed-piece, and the emery-stone acts upon the teeth as they are consecutively brought into position beneath it. The emery-stone frame has oscillation in a vertical plane, to bring it down to or away from its work, and has also a longitudinal movement, to pass along the edge of the cutter.

Fig. 3248.



Mowing-Knife Grinder.

Mox'a. (*Surgical.*) A substance burnt on the skin to form an ulcer. The soft, woolly leaves of the artemisia are used. Dr. Brown-Sequard repeatedly applied moxas to the back of our late Senator Sumner. He regarded the treatment as the most severe he had ever applied to any living creature, — not excepting his guinea-pigs, which, in various states of dilapidation and destitution of limbs and nerves, were all eaten by the Parisians during the siege.

Mo'zam-bique'. (*Fabric.*) An open dress-goods having a chain in which the cotton threads are associated in pairs, and the woolen filling is soft and fleecy. It is dyed in the wool, self-colored, or striped in the warp.

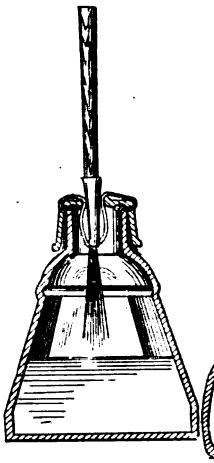
Mox'ing. Gigging of cloth.

M-roof. (*Carpentry.*) A double roof consisting of two ordinary gable-roofs and a valley between them.

M-teeth. (*Saw.*) Teeth in groups of two, like the letter _M_M_.

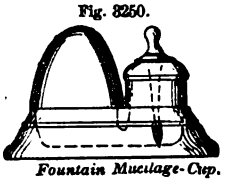
Mu'ci-lage-bot'tle. One for containing mucilage, a solution of gums tragacanth and acacia. In the example (Fig. 3249), an elastic band is applied to the stem of the brush and the cover of a mucilage, marking, or other bottle, for the purpose of always keeping the brush elevated above the contents of the bottle, except when forced down for the purpose of taking up some of the fluid for use.

Fig. 3249.



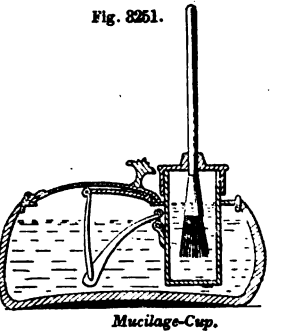
Mucilage-Bottle.

Fig. 3250.



Fountain Mucilage-Cup.

Fig. 3251.



Mucilage-Cup.

Fig. 3250 has a supply fountain.

In Fig. 3251, a water-tank forms a receptacle for the brush. The lid is attached to a rod which swings back with it and forms a wiper for the brush.

Muck-bar. Bar-iron which has passed once through the rolls. It is usually cut into lengths, piled, and rerolled.

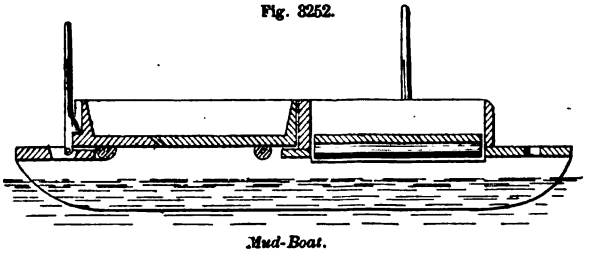
Muck-fork. (*Agriculture.*) A manure-fork.

Muck-rake. (*Agriculture.*) A drag or rake for removing or unloading manure.

Muck-roll. The *roughing* or first roll of a rolling-mill train.

Mud-boat. One for carrying off mud dredged from a river-channel or bar, and having convenient provision for discharge. In the example, the mud-boat has several vats resting on two boats which are placed parallel and connected by timbers. The floors of the vats have sectional drops for discharge, and

Fig. 3252.



Mud-Boat.

Digitized by Google

lever-catches which control their discharging functions.

Mud-drag. A machine for raking up the mud of a river, in order that it may be carried off by the current. A *hedge-hog*.

Mud-hole. A covered opening in the bottom of a boiler for discharging the dirt and sediment.

Mud-pat'tens. Broad wooden sole-boards for traveling on mud-lands.

Mud-plug. (*Steam-engine.*) A tapered stopper, removed from a boiler to allow the mud to escape.

Mud-sill. The lowest sill of a structure, which may be in the mud or on the surface of the earth.

Mud-valve. (*Steam.*) A valve by which mud is discharged from a steam-boiler.

Mud-wall. One of earth or clay.

One of materials laid in clay as a substitute for mortar.

Muff. 1. (*Glass.*) A roller or cylinder of glass for flattening out into a glass plate.

2. (*Wear.*) A fur pocket for the hands held in front of the person.

"This day I did first wear a muffle, being my wife's last year's muffle, but now I have bought her a new one." — PEPYS's *Diary*, November 30, 1662.

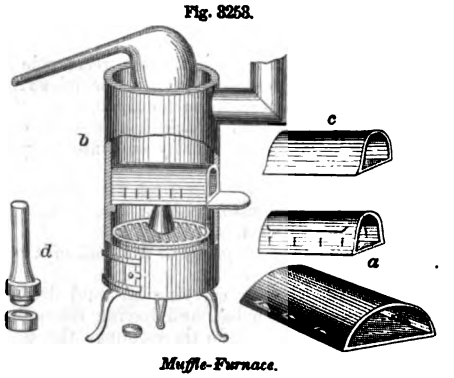
3. A joining tube driven into the ends of two adjoining pipes.

Muf'fle. 1. (*Metallurgy.*) An oven-shaped vessel (*a*) of baked fire-clay, used in assaying for containing the cupels or cups in which the alloy under investigation is fused. It is open at one end and closed at the other, and has slits in the sides to permit a draft of air through it. Its use is to protect the cupels from impurities of fuel while permitting access of air. It forms a chamber in the midst of the incandescent coals of the furnace *b*. See MUFFLE-FURNACE; ASSAYING-CUPEL.

2. A pulley-block containing several sheaves.

Muf'fle-fur'nace. (*Metallurgy.*) A furnace with a chamber which is surrounded by incandescent fuel,

Fig. 3253.



Muffle-Furnace.

and in which cupellation or fusion of metals is performed; the former especially. (See CUPELLATION.) The holes in the sides of the muffle are important, as through them a draft is established which oxidizes the lead and some other associated metals.

a, muffle. *c*, closed muffle.
b, muffle-furnace. *d*, cupel-mold.

In the process of assaying, the *muffle* contains the cupel in which the metal is placed.

Arsenic is sublimed from arsenical pyrites in a muffle whose eduction-channel leads to a condensing chamber where the arsenious acid is deposited. See ARSENIC-FURNACE; CUPELLATION.

Muf'fler. 1. (*Music.*) A soft cushion employed to terminate or soften a note.

2. A knit wrapper for the head or throat.

Mule. A spinning-machine in which the rovings are delivered from a series of sets of drawing rollers to spindles placed on a carriage, which travels away from the rollers while the thread is being twisted, and returns toward the rollers while the thread is being wound.

It was invented by Samuel Crompton, and perfected in 1779, so far as to make it an excellent working machine. Subsequent improvements by Roberts, Mason, and others have brought it to its present state, in which it is automatic, and is known in some parts of England as the "iron man," in allusion to its singularly deft and delicate action.

The combination which gave rise to the term *mule* was the junction of the *drawing-rollers* of Arkwright with the *jenny* of Hargreaves. The hybrid scarcely came within the definition of a *mule*, which is declared by Senator Nesmith of Oregon to be "a being without pride of ancestry or hope of posterity." The object of the machine is to deliver the roving with the required degree of attenuation and twist it as delivered. For this purpose, the spindles, instead of being stationary, are placed on a movable carriage, which is wheeled out to twist the threads and wheeled in again to wind on the spindles.

Mr. Kennedy, the friend and biographer of Crompton, states: —

"The great and important invention of Crompton was his spindle-carriage and the principle of the thread having no strain upon it till it was completed. The carriage with the spindles could, by the movement of the hand and knee, recede just as the rollers delivered out the elongated thread in a soft state, so that it would allow of a considerable stretch before the thread had to encounter the stress of winding on the spindle. This was the corner-stone of the merits of his invention."

Crompton's mule was also termed the *muslin machine*, from its producing yarn finer and softer than was obtained from any other machine then known, more nearly to the standard of the India muslins, which are yet the admiration of the cotton-trade.

Crompton gave up his invention to the public in 1780. Thirty-two years afterward he received £5,000 from government as a compensation for his services. This was unfortunately frittered away in starting his sons in business, and the father was again in poverty. A subscription was raised for him which supported him during the last two years of his life. He died in 1827.

Crompton obtained no patent, and his poverty was not rendered additionally miserable by vexatious litigations and hopes deferred. There seems to have been no conscience among manufacturers as to the right of property in patents during the period marked by the inventions of Hargreaves, Arkwright, and Watt. The latter two, by indomitable energy and the possession of partners of skill, capital, and business tact, survived the attack of the Ishmaelites, and left honored names and good estates. (See SPINNING.) Crompton's first machine contained only 20 or 30 spindles, and was built to supply his own loom with good yarn. The traverse of the mule-carriage was only 5 feet. The distance traveled is now much greater, and the carriage sometimes carries 1,000 spindles.

Previous to the invention of the mule few spinners could make yarn of 200 hanks to the pound, the hank being always 840 yards. The natives of India were at the same time making yarns of numbers ranging from 300 to 400. Houldsworth of Manches-

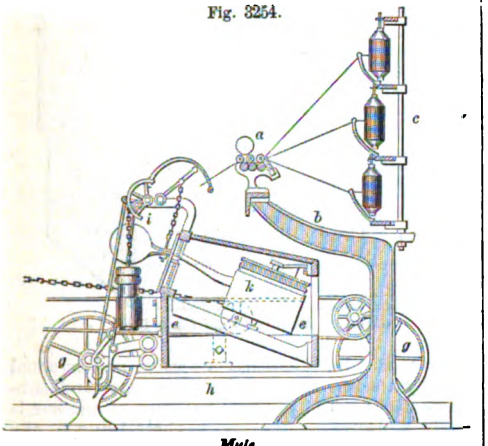
Digitized by Google

ter, England, has lately succeeded in making No. 700, which was woven in France.

Mr. Roberts invented the self-acting mule in 1825. By this, the carriage, after the thread is spun, is automatically returned to the rollers, requiring no attendance, except for the purpose of joining threads which may be accidentally broken. This is performed by children.

In Fig. 3254, *a* is the triple set of drawing rolls, working in heads fixed on the roller-beam *b*. *c* is the creel for holding the bobbins in three rows. *e e* is the carriage, resting on wheels *g g*, which run on the railway *h*. Spindles *i* are set in a nearly upright po-

Fig. 3254.



Mule.

sition. *k* is one of a series of drum-cylinders with grooves around the upper end for the driving band.

This machine is not self-acting, but illustrates the principle of action.

The drawing and stretching action of the *mule-spinner* makes the yarn finer and of a more uniform tenuity than the mere drawing and twisting action of the *throstle*. As delivered by the rollers, the thread is thicker in some parts than in others; these thicker parts, not being so effectually twisted as the smaller parts, are softer and yield more readily to the stretching power of the mule; by this means the twist becomes more equable throughout the yarn. Throstle-spinning is seldom employed for numbers higher than 40 or 50 hanks to the pound, because smaller yarn would not have strength to bear the drag of the bobbin, but in mule-spinning the yarn is built upon the spindles without subjecting it to appreciable strain.

The mule-carriage carrying the spindles recedes from the rollers with a velocity somewhat greater than the rate of delivery of the reduced roving, the rapid revolution of the spindles giving a twist to the yarn, which stretches it farther. When the rollers cease giving out the rovings, the mule-spinner still continues to recede, its spindles still revolving, and thus the stretching is effected.

The distance to which the spindles recede from the rollers while both are in action is called a *stretch*. This is usually about 54 to 56 inches.

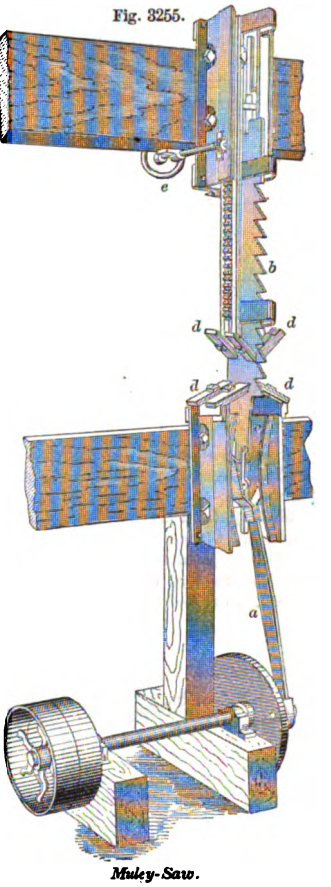
The space over which the carriage moves in excess of the paying out of the rollers is called the *gaining* of the carriage.

The space traversed by the carriage after the paying-out action of the rollers is stopped is called the *second stre'ch;* during this latter the spindles are revolved very rapidly, to save time.

When the *drawing*, *stretching*, and *twisting* of the yarn are thus accomplished, the mule disengages itself from the parts of the machine by which it has been driven, and the carriage is returned to the rollers, the thread being wound in a *cop* upon the spindle as the carriage returns.

The specific difference between the action of the throstle and the mule is, that the former has a continuous action upon the roving, *drawing*, *twisting*, and *winding* it upon the spindle; while the mule *draws* and *twists* at one operation as the carriage runs out, and then *winds* all the lengths upon the spindles as the carriage runs in.

Fig. 3255.



Muley-Saw.

Mu'let; Mu'-lette. A Portuguese vessel with three lateen sails.

Mu'ley-head. The sliding carriage to which the muley-saw is attached, and which moves in guides on the frame of the mill. The saw is attached to a *muley-head* at each end.

Mu'ley-saw. A mill-saw (German, *mühlsäge*, mill-saw) which is not strained in a *gate* or *sash*, but has a more rapid reciprocating motion, and has guide-carriages above and below, called *muley-heads*.

Mull. (Fr. *molle*.) A thin, soft, cotton goods. Varieties are known as Swiss, India, starched mull, etc.

Mul'lar. A stamp with an intaglio ornament, for giving a salient impression to metal upon which it is struck.

Mul'ler. A grinding apparatus consisting of a stone or slab with a flat surface, which is moved upon a stone table or slab to grind and mix pigments, etc. The action is sometimes called porphyrization.

A painter's stone and muller, much like the modern, were disinterred from an Egyptian tomb, and are now in the Abbott collection.

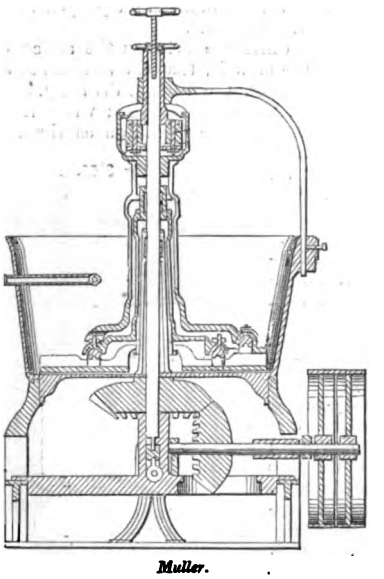
The mulling action is shown in the mill (Fig. 3256). This is a form of amalgamating pan in which the mullers are attached to two sets of arms, and rotate in the pan in different directions by means of gear-wheels and an axial shaft, which passes down through the bottom of the pan, and is put in motion by gearing. See list of allied devices under MORTAR; MILL; ORE-MILL.

Mul'lion. 1. A vertical bar separating the compartments of a window, especially used in the Gothic

Digitized by Google

and double-casement windows. The horizontal bars are *transoms*. *Munnion, monycale, monial.*

Fig. 3256.



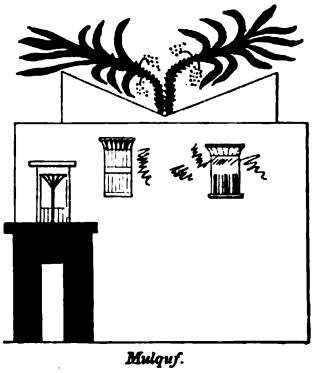
Muller.

2. A style or upright division in wainscoting.

Mull-mus'lin. (*Fabric.*) A thin, soft, transparent muslin. Finest quality.

Mul'quf. Perhaps the most ancient device for ventilating, specially constructed for that purpose, is the *mulquf*, which has been in use in Egypt for at least 3,000 years, and is still to be seen attached to the modern houses of Cairo and other towns. The name

Fig. 3257.



Mulquf.

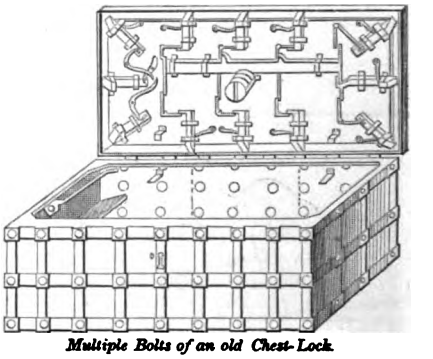
is Arabic, and means *wind-conductor*. It is open in the direction of the prevailing wind, which is conducted down the descending chute and thence disseminated through the house. The illustration is from an ancient drawing in a tomb at Thebes. Wilkinson states that it consists of a strong wooden framework to which planks are nailed, according to the length and breadth desired. If cheaper materials be required, the framework is covered with reeds or mats, plastered. The illustration shows two, presented respectively, it may be assumed, up and down the river. They are common features in Cairene architecture, where their presentation is usually N. W., being toward the prevailing wind.

Mul'ti-flue-boil'er. A steam-boiler having a large number of moderate-sized or small flues, as that of a locomotive.

Mul'ti-ple Bolt. An arrangement by which a number of bolts are simultaneously moved. It was a common feature on the strong-boxes of other days, and has been revived upon safe-doors.

The engraving represents an old French lock, with four corner bolts, six others on the sides, and two

Fig. 3258.



Multiple Bolts of an old Chest-Lock.

on the ends. Each bolt has a spring, and is acted upon by a lever, operated by the central and subsidiary bolts. The keyhole in front of the box is merely a deception, the real keyhole being in the middle of the lid, concealed by a secret door opened by a spring.

Mul'ti-ple Wheel. The rollers on the arms of the smaller wheel traverse in the diametric grooves on the face of the larger wheel, and impart motion to the latter.

Fig. 3259.

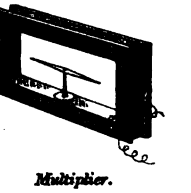
Multiple Gearing.

One revolution of the smaller wheel gives half a revolution to the larger. If the *larger* wheel be the *driver*, two revolutions of the smaller wheel are obtained for one of the driver.

It is substantially the same as the *slosh-wheel*, which has two diametric grooves and two slides. The relation of speed is the same in each. See SLOSH-WHEEL; TRAMMEL.

Mul'ti-pli-er. 1. (*Telegraphy.*) A frame with a number of repetitive windings of the same wire, in order to obtain their cumulative effect in deflecting a magnetized needle, when the wire is traversed by a current. An invention of Schweiger.

Fig. 3260.



Multiplier.

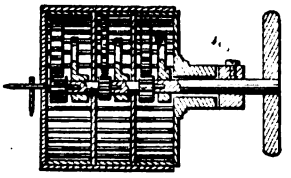
Unless the current is sensibly diminished by the resistance of the wire, each convolution exerts an equal force on the needle, thus multiplying the deflective force as many times as there are turns in the wire. Owing to the resistance, however, it frequently occurs in practice that a few turns of stout wire exert a greater influence on the needle than numerous convolutions of much finer wire.

2. An arithmometer for performing calculations in multiplication. See ARITHMOMETER.

Digitized by Google

Mul'ti-ply-ing-gear'ing. An arrangement of cog-wheels by which motion is imparted from wheels of relatively larger diameter to those of smaller, so as to increase the rate of rotation. This is used in many kinds of machinery. The example shows a nest of gearing for increasing the rate of motion from the driving-shaft of a harvester to the rate required by the cutter-bar. The motive shaft has arms which carry spur-wheels engaging the inner gear of the drum, and a pinion which is fast to the second shaft, having similar arms and spur-wheels engaging a pinion on the third shaft. This may be extended as far as desired; the proportion between the planet-wheels and their pinions regulates the increase of speed gained.

Fig. 3261.



Multiplying-Gearing.

Multiplying-gearing is also used with some forms of propeller-engines.

Mul'ti-ply-ing-glass. One with a number of facets repeating the object. A toy.

Mul'ti-ply-ing-lens. A plano-convex lens whose curved surface is divided up into a number of plane facets which give separate images.

The facets of a multiplying-lens or a cut diamond resemble those of the compound eye of some insects. Each little facet of the cornea gathers a certain set of pencils of light, and the main necessity for the motion of the eyeball is avoided. The facets in the compound eyes of the insects following are cited as,

The butterfly	17,335
The dragon-fly	12,544
The house-fly	7,000

The eye of a flea has been so mounted with the assistance of a microscope as to exhibit a flame or other object as a grand miniature illumination or assemblage.

Mul'ti-ply-ing-ma-chine'. One form of calculating-machine. See Fig. 328, ARITHMOMETER. See also CALCULATING-MACHINE.

Mul'ti-ply-ing-wheel. One which increases the number of movements in machinery. See MULTIPLYING-GEARING.

Mul'ti-tu'bu-lar Boil'er. One having numerous tubes in which water circulates.

Mun'go. (*Fabric.*) A woolen cloth made of second-hand material. Old cloth and woolen goods are torn to pieces by cylindrical machines, and, being mixed with various proportions of pure wool, are re-spun and woven. Druggets and low-priced goods of but little strength are the result. *Shoddy.*

Mun'nion. 1. (*Ship.*) A piece which divides the lights in a window of a stern or quarter gallery.

2. A bar separating the compartments of a Gothic or casement window. A *mullion.*

Mun'tin. (*Carpentry.*) A vertical piece between the panels of a double-panel door. The name is probably derived from *munnion*, and that from *mullion*, a pier between the divisions of a Gothic window. Mullion is from *molding* (Fr. *moulure*), signifying the form.

Muntz's Met'al. An alloy for plates for sheathing the bottom of ships. Patented in England in 1832. It resembles several previously patented alloys, all of which were designed to be rolled while red-hot, and to be used for the purpose stated.

See the following; also table on page 61.

Copper . . .	54	55.5	50, 60, 63
Zinc . . .	40	44.4	50, 40, 37
Iron . . .	5.4		

Mu'ral Cir'cle. An astronomical instrument consisting of a graduated circle, furnished with a telescope and firmly affixed to a wall, in the plane of the meridian. It is used for determining with great accuracy altitudes and zenith distances, from which may be found declinations and polar distances, and has a graduated circle secured at right angles to its horizontal axis. See TRANSIT.

The old Hindoo instrument for obtaining by observation the sun's altitude and zenith distance is described in the Sanscrit treatise "Sûrya Siddhânta." It was a wheel suspended by a string, graduated to degrees, having its lowest point and the extremities of its horizontal diameter distinctly marked, and with a projecting peg at the center. When used, its edge is turned toward the sun, so that the shadow of the peg falls upon the graduated periphery, and the distances of the point where it meets the latter from the horizontal and lowest points of the wheel respectively are the required altitude and zenith distance of the sun.

Among celebrated instruments may be mentioned the mural circle made by Graham, for Halley, at Greenwich, and those made by Ramsden in 1788, for Piazzi, at Palermo, and one for Dublin. See GRADUATING-INSTRUMENTS.

The *mural circle* is so called because it is supported by means of a long axis passing into a wall.

The mural circle of the National Observatory in Washington was made by Mr. William Simms of London. It is 5 feet in diameter, made of brass, and cast in a single piece. It is divided into spaces of 5′ each, upon a band of gold inlaid on the rim and perpendicular to the plane of the circle. Placed at equal distances round the circle are six micrometer microscopes, with an acute cross of wires at their foci for reading angles less than 5′. Five revolutions of the micrometer are designed to measure 5′ upon the circle. The micrometer heads being divided into 60 equal parts, each division represents 1″ of arc. The object-glass of the telescope has a clear aperture of 4 inches and a focal length of 5 feet. At its focus is a fixed diaphragm containing seven vertical wires and one horizontal wire. There is also another diaphragm, movable by a micrometer screw, and furnished with five horizontal and equidistant wires, by which the distance of any star from the fixed horizontal wire is measured as it passes through the field. The magnifying power usually employed is 125. The cost of the mural circle was $3,550.

The mural circle is placed in the meridian, and is used for determining the polar or zenith distances of celestial objects.

Mural quadrants and *mural sectors* are instruments of lesser arcs, similarly mounted.

Mu'ral Quad'rant. Differs from the preceding in the merely quadrantal character of the graduated arc.

The mural quadrant of Tycho Brahe at Uranibourg had a radius of five cubits. The collection of astronomical instruments at this observatory was by far the finest that had ever existed.

Mu-rom'e-ter. An instrument for measuring small spaces. — WEALE.

The term may refer to a mural attachment, as in the case of the mural circle, for measuring arcs of the meridian. The instrument is permanently attached to a perpendicular wall.

Mu-sette'. (*Music.*) A name by which the bagpipes are known among some of the European conti-

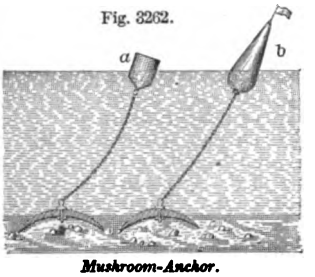
Digitized by Google

nental nations. Named from a mountebank performer.

Mush'room-an'chor. An anchor with a central shank and a head like a mushroom, so that it can grasp the soil however it may happen to fall. Invented by Henman of Chatham, England, 1809. See ANCHOR.

That used by the United States Lighthouse Board for anchoring buoys is shaped like an inverted saucer, having a shackle and

Fig. 3262.



Mushroom-Anchor.

chain attached to the center of its convex side. The chain is just long enough to give the buoy sufficient prominence above the surface and allow for the rise and fall of tides.

It imbeds itself in the ground, offering a strong resistance to an upward pull and not a little to a lateral one.

a, *can*-buoy with anchor.

b, *nun*-buoy with anchor.

Mu'si-cal Box. (*Music.*) A small musical instrument having a toothed barrel operating vibrating tongues.

Mu'si-cal Clock. One which plays tunes at the hours. It may consist of a musical-box attachment set in motion by the clock-work at the expiration of the hours.

One of late construction is cited as having a large bell on which the hours are struck, a chime of eight bells for the quarters, and a four-bell chime for "Cambridge quarters." It will also play seventy different tunes upon sixteen bells, the tune being selected by turning a hand on a dial; and by means of pushing a small stud the same tune may be repeated any number of times. There are ten barrels, each adapted for seven tunes, and readily substituted one for another. Other musical clocks are also provided with mechanical movements, dancing figures, soldiers marching past to the tunes played on the bells, all automatic. See also CLOCK, pp. 568–71.

Mu'si-cal Com'pass. (*Music.*) The range of notes of the voice or of a musical instrument.

Ptolemy first described the diatonic scale now in use. It appears that the ancients had no notation for time, and no music in parts; even their melodies were formed on different principles from the modern. Pope Gregory the Great (A. D. 590) denoted the scale by seven Roman letters, which represented in different octaves replicates of the same sound. Previous to this the sounds in the double octave had been denoted by fifteen letters. The letters of Gregory were placed over the syllables to which they were to be sung. Afterward, a little higher or lower than a median line, as an assistance in reading the notes. At a later period, on seven lines, in imitation of the strings of a lyre. Guido of Arezzo, a Tuscan monk (about 1022), reduced the number of lines to five, and placed the points of notes on lines and spaces. He also introduced *solmization*, or singing by syllables, as in the *do*, *re*, *mi*, *fa*, yet used, though not exactly so called. Bars were first used in the beginning of the seventeenth century.

Fig. 3263.

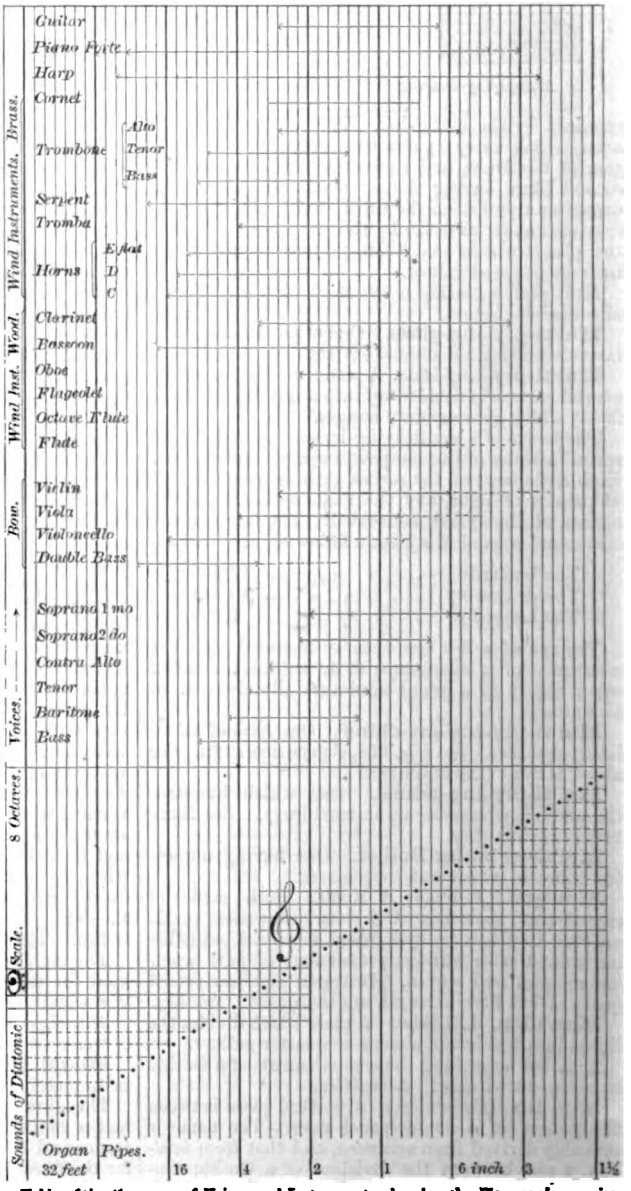


Table of the Compass of Voices and Instruments, showing the Place each occupies in the Scale.

The original compass of the piano-forte was 5 oc-

Digitized by Google

taves. This was gradually extended to 6½ and 7 octaves, the latter being the usual range on grand-pianos. See PIANO-FORTE.

Piano-fortes were exhibited in London, 1851, with 7½ and 8 octaves.

Mu'si-cal Glass'es. (*Music.*) A musical instrument consisting of a number of goblets, tuned by filling them more or less with water, and played by touching their rims with the dampened finger. The size of the glasses being equal, the smaller quantity of water produces the lower note in the scale.

The instrument was revived and improved by Benjamin Franklin in 1760. See HARMONIUM.

Mu'si-cal In'stru-ments. Devices designed to create a succession of harmonious sounds are to be found at the earliest historic periods, including under that term the times when men wrote by pictures, long before phonetic signs and syllables were invented.

We find them among those races which stand low down in the scale of humanity, and ancient monuments show that at a very distant period they had advanced to a considerable degree of perfection.

> "The birds instructed man,
> And taught him songs before his art began.
> And while soft evening gales blew o'er the plains,
> And shook the sounding reeds, they taught the swains;
> And thus the pipe was framed, and tuneful reed."
> LUCRETIUS, *De Rerum Naturæ*, B. V.

The musical instruments of a rude people are themselves rude. Those of the Feejees are the conch-shell, nose-flute, pipes, a jew's-harp made of a strip of bamboo, and drums.

The Maories have three or four varieties of flutes, a lyre with three or four strings, and conch-shells.

The Society-Islanders have wooden drums with shark-skin heads; shell trumpets having holes in the small ends into which are fitted bamboo canes about three feet long; bamboo flutes blown through the nose.

A greater variety and improved construction indicates a more advanced civilization.

In the sculptures and paintings of Karnak are representations of musical instruments carried in processions. They consist of harps, maces, sistrums, lutes, flutes, and drums.

We suppose musical science and art to have originated in Egypt, — the land where, over all others, the husbandman could tell when he sowed his grain how much he was to reap in harvest; where the chances were reduced to the minimum; and where, first of all lands, a cultivated leisure was possible.

The musical instruments of Egypt utterly disprove the statements of Diodorus Siculus, that music was unknown in that country. A remarkable instance, which may stand as a complete refutation, is found in the harps discovered by Bruce depicted upon a tomb near the ruins of Thebes. These were so superior to the harps of 100 years since, that doubts were entertained of the fidelity of the representation; but Rosellini's "Monumenti dell' Egitto," and Wilkinson's "Ancient Egyptians," have removed all doubts. (See HARP.) The testimony of Herodotus, Plato, and others also enforces the statement, that music arose in Egypt and came thence to Greece.

When the Israelites left Egypt, they carried away with them some of the arts with which they had become acquainted in their at first voluntary and subsequently enforced stay.

According to Father Kircher, thirty-six kinds of instruments played by striking were employed by the Jews in the service of the Temple. Others reduce the number to twenty-two. Among these, the class termed *neghinoth* included stringed instruments of a long oval or rounded shape with perforated bottoms; the strings, three in number, were struck by a horse-hair bow. These were called *trichordon* in Greek, and *trifidium* in Latin.

Other instruments of the kind were the *psalter*, *nablium*, or *cithara*, denominated by the Hebrews *assur*, *nevel*, *kinnor*, *maghul*, *minnim*.

Of these no intelligible description remains. Some have supposed that the *psalter* was not in fact an instrument, but that the term was applied merely to harmony produced by the voice in conjunction with instruments. According to Josephus, however, it was an instrument with twelve strings played on by the fingers. The general opinion is that it was a species of harp.

The Hebrew drum, termed *thoph*, appears to have been covered at one end only. It was struck with a rod of wood or iron, and is said to have been of Egyptian origin. (See DRUM.) The *gnesto berusim*, according to Rabbi Hannase, was a species of wooden mortar struck on the interior with a rounded stick.

The *maghul* is believed to have been a stringed instrument, but was, perhaps, a circle surrounded by little bells. A tambourine.

The *minghinim* has been confounded with the psalter and the cymbal, but Kircher states that it was a quadrangular plank, having a handle, to which small globes of wood and copper were attached by chains and cords, producing a clear jingling sound which could be heard at a considerable distance. Perhaps a kind of sistrum.

The *magraphe temid* was used to call the people to the Temple. Kircher supposes it to have been similar to a bell, but as no description remains this is a mere matter of inference.

The *mafra kitha*, according to Kircher, was composed of a series of reeds of different sizes inserted into a hollow piece of wood. It had holes opened and stopped by the fingers similarly to the flute.

The Hebrews employed at an early period the horns of animals as musical instruments, and also made flutes from the leg bones of birds, as the crane and stork.

According to Josephus, no less than 40,000 instruments were collected by Solomon for the service of the sanctuary, divided into different classes appropriate for each class of the services.

With regard to the form and use of many instruments employed by the ancients, no authentic account remains. In many instances conjecture has been substituted for fact.

They were generally used at festivals and religious ceremonies, are frequently mentioned by Ovid and other poets, and some are shown on ancient marbles.

Athenæus states that in the triumphal procession of Ptolemy Philadelphus there were 600 musicians in the chorus, 400 of whom played on the cithara or lyre.

Then, as now, musical instruments were ranged in three great classes, — wind, string, and percussion. In Numbers, chap. xix, the Hebrews are directed to sound trumpets on going into battle, and the walls of Jericho fell at the sound of the trumpet. This has been the warlike instrument of all nations from the earliest ages, except the Spartans, who employed pipes and soft instruments to temper rather than inflame their martial ardor.

Trumpets with two tubes were sometimes used by the ancients. At a later period the tube was recurved, as in the modern trumpet, of which the bugle is a variation. The trumpet used in Persia and the East is a very long tapering tube with flar-

Digitized by Google

ing mouth. A similar instrument without a flaring mouth is used in Turkey and India.

The Chinese have trumpets of wood.

The Florida Indians, according to the history of Jacques Le Moyne, made a species of trumpet by winding the bark of trees spirally, forming a tube wider at one end than the other, to which oval plates of gold, silver, or other metal were attached by strings, intended apparently to jingle in accord with the instrument.

The Greeks ascribed the invention of the three-stringed lyre to Thoth, the Egyptian Mercury; and Terpander, the Greek, is credited with founding the Greek music, and with the invention of the seven-stringed lyre. He also contrived a method of representing musical sounds, writing music. Pythagoras added an eighth, completing the octave. The Greeks excelled in the use of the flute, using a variety of instruments of different pitch, but probably played in unison, not in harmony. It is apparently well settled that they did understand counterpoint.

The Romans seem to have added nothing to the art.

Toward the end of the fourth century, St. Ambrose composed a musical service for the church of Milan. Previous to this time, the Christian service was probably various in different parts of the Empire: in some it doubtless was Oriental and noisy; in lands where the Grecian civilization prevailed, it was copied from the dramatists, and consisted of airs, recitatives, and responses; in other regions again it probably followed the chants as performed at the pagan altars, and among the Christianized Jews it doubtless long followed the Hebrew models.

Two tubes, one sliding within the other, a form from which the trombone is derived, appear to have been early employed. See Plate V., Bonanni's "Istromenti Armonici," Roma, MDCCLXXVI.

From being at first straight, the tube was made curved, slightly, perhaps, at first, afterwards so as form a semicircle or more, and then so as to make one or more convolutions like the modern French horn.

Tyrrhenus, son of Hercules, it is said, first employed a sea-shell, perforated at the smaller end, as an instrument of music. The tritons attendant on Neptune are represented as blowing sea-shells.

The flute was originally sounded by a mouth-piece at the end, like the clarinet. In this form it is of great antiquity. The German flute is a comparatively modern invention. See FLUTE.

The ancient flute was frequently made double, the tubes diverging outwardly from the mouth. From an instrument of this kind to the compound or pandean pipes the transition is easy, and we accordingly find the latter in vogue at a very early period. The Chinese *tam-kim*, which is played by opening and closing the ends of a series of pipes filled by a single mouth-piece, is an analogous device. See Plate XLIII., Bonanni, *supra*.

The bagpipe is said to have come from Lydia, and is mentioned by Suetonius in his life of Nero. See BAGPIPE.

The organ is of great antiquity, but the word "organ" is applied in the Bible, according to St. Augustine, to a variety of instruments. The invention of the hydraulic organ is attributed to the Alexandrian Greeks. (See ORGAN.) The pneumatic organ, even in its most primitive form, does not appear to have been used prior to the seventh century.

The *cithara*, or an equivalent instrument, is the most ancient of the stringed class known, being mentioned in the fourth chapter of Genesis; Jubal having been the progenitor of such as handle the *harp* (or cithara) and *organ*. The connection between instruments of this kind, as the lyre, harp, and others on the same principle, is so close that we can hardly decide positively which is the primitive form. The monuments of Egypt illustrate a number of varieties. See HARP; LYRE; LUTE.

The *violin*, *guitar*, *mandolin*, and similar instruments are of later origin. The first were struck by a *plectrum*, or a small rod, or by the fingers. See GUITAR.

The *monochord* and *tromba marina*, or marine trumpet, are played with a bow. (See Plate LXIV., Bonanni.) The latter has merely a flat sounding-board, on which the single string is stretched.

The so-called German lyre is a *hurdy-gurdy*.

The Kaffirs have a species of *monochord*, consisting of a string stretched on a bow and twanged with an ornamented swan-quill, and a sort of violin formed by stretching a string over a kind of drum with a handle. This is played with a bow.

Instruments played by percussion seem to have been among the first known. Miriam is represented as playing on the *timbrel* after the passage of the Israelites across the Red Sea. (Exodus, chap. xv.) This appears to have been similar to the tambourine, and was also probably surrounded by little bells. See TAMBOURINE.

The *tam-tam*, formed by stretching a skin over the opening of a hollow hemisphere, cylinder, quadrangular box, or even a gourd, and beaten with a stick, has been found among all races and tribes of people. See DRUM.

The *maramba*, formed by thus preparing a number of gourds of different sizes so as to accord with one another, is in use alike among the inhabitants of Africa and Southern America. Bamboos similarly attuned and arranged are also employed by some African tribes.

Drums, *tam-tams*, and *gongs* are much in vogue among the Chinese and other imperfectly civilized or barbarous nations, with whom noise and music are synonymous terms. With nations having more appreciation of harmony, such instruments have been more sparingly employed, for the purpose of marking time or of reinforcing the sound of a combination of other instruments at proper intervals.

The *sistrum* and *crotalus*, or rattle, jingling devices caused to sound by shaking, were used in former times with this view; but at the present day, with the exception, perhaps, of the cymbals and triangle, instruments of the jingling and clashing kind are banished from the orchestra. See CASTANET; CYMBAL; TRIANGLE; GONG; BONES.

The arrangement of bells in a diatonic series, so as to play tunes, is of comparatively modern origin. See PAVILLON CHINOIS; CARILLON.

For a list of the more generally known instruments, see specific index, next page.

The following list and classification of musical instruments is given in Berlioz's "Treatise upon Modern Instrumentation and Orchestration":—

STRINGED INSTRUMENTS.	Vibration effected by the bow	Violin. Viola. Viole d'amour. Violoncello. Double-bass.
	Played by the hand .	Harp. Cithern. Guitar. Banjo. Mandolin.
	With keys . . .	Piano-forte.

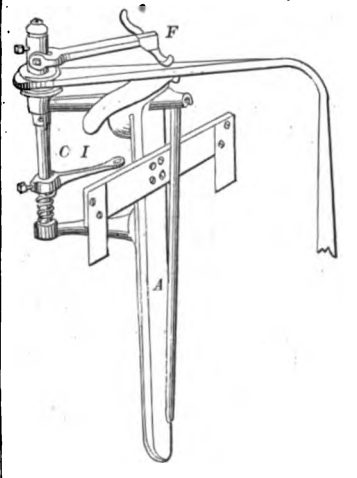
Staccato.	Trombone.	Wood-harmonicon.
Stop.	Trumpet.	Zithern.
Syrinx.		

Mu'sic-box. (*Music.*) An automatic playing instrument in which a row of vibrating tongues are tripped by pins on a barrel rotated by a spring. Boxes are made on a small scale for two tunes, and of many other sizes, some very large, expensive, and having a capacity for playing many tunes. The rapidity of the successive notes is such that it is impossible to make one tongue make the requisite number of notes in succession without striking upon the following pin; therefore, there are two, three, or four teeth of the comb having the same tone or pitch, and placed contiguous, which allows the rapid recurrence of the same note by placing the pins side by side, following, instead of behind each other. The regulator, or *fly*, is adjustable; the wings which impinge against the air are capable of limited extension and contraction, thus retarding or accelerating the rate of revolution of the cylinder.

The tones of the tongues are regulated by their length and thickness; the shorter they are, the quicker the vibrations, and the higher in the scale is the pitch. To the long teeth, which are to vibrate slowly for the low notes of the scale, are attached masses of lead of sufficient weight to give the requisite tone. The tuning of these teeth is accomplished by altering their thickness by stoning, filing, or scraping, till the proper pitch is obtained. To prevent too long vibration of any of these teeth, a system of dampers is employed; on the under side of the longer tongues small pieces of steel spring are attached; to the middle teeth of the comb small bits of goose-quill are attached by cement, the short teeth, having a short vibration, requiring no dampers.

Fig. 3264.



Music-Leaf Turner.

Fig. 3265.

Music-Pen.

Mu'sic-clamp. A temporary binder or file for holding sheet music in convenient form for use and preservation. See PAPER-CLAMP.

Mu'sic-leaf Turn'er. The arm *A* is

held to the music-stand by a clamping piece; the fingers are inserted between the pages and turned by the ratchet-plate *F*, which slides freely over the fingers when turned in one direction, but engages them one by one when it is moved in the opposite direction. It is fixed on the spindle *C*, which is partially rotated by the arm *I* connected by a cord with a treadle, and is restored to its former position by a spring.

Mu'sic-pa'per. Paper ruled with lines for writing music.

Mu'sic-pen. A pen made for ruling at once the five lines which, with the intervening spaces, form the staff of music. The instrument has a brass head and five parallel pens like ruling pens; that is, they consist of bent strips of brass which form spouts to conduct the ink from the reservoir to the paper.

Mu'sic-print'ing. Music was first printed by types on which the ledger lines were cast. The font displayed all possible variations of character and position. In 1720, music was engraved on plates.

Breitkopf's type, 1764, had the ledger lines on separate type. Reinhard printed the ledger lines from engraved plates, and the notes from type at a second pull.

Another and more modern plan is to put up the ledger lines in rules and cast the type so as to admit of the ledger line crossing them when necessary.

Music has been for a long time engraved by cutters and punches on soft metal plates and printed by the copperplate press.

The compositor, having the manuscript of the music before him, selects a thin sheet of soft metal of the proper size, and sinks, by the use of a machine constructed for the purpose, the staff-lines into the metal. He then proceeds to sink in the notes, rests, points, bars, slurs, etc., by the use of suitable punches, each musical character or element of a character having its appropriate punch.

The plates thus prepared have thus produced upon them the piece of music in sunken characters, which characters are next filled up nearly to the level of the plate with beeswax. The musical notation now appears as if printed in wax upon the plates, the surfaces of which are highly polished.

To print from these plates the ink is first distributed uniformly over the entire surface by a hand-roller. The surfaces are then wiped off with a cloth, which removes all the ink from the polished parts, while it still adheres to the wax in the punched depressions.

The pressman lays the paper upon the surface of the plates, and then passes them through the ordinary copperplate D-press. While the above is the usual plan adopted for preparing plates for the best music, a very large proportion of the music of the present day admits of being set up for the usual letterpress printing. The *sorts* of the case embrace all the various possible requirements of the music.

Mu'sic Re-cord'ing-in'stru-ment. A machine to record the notes played upon a keyed instrument.

The organ or piano is connected with the recording apparatus by a magnetic telegraph. Beneath each note of the three manuals and of the pedals, and connected with each stop of the organ, is a small brass spring, which is pressed down whenever the piece to which it is attached is brought into action. From each spring wires run to a galvanic battery, and to the recording apparatus, which may be situated at any convenient distance from the organ. When the spring is pressed down, connection between the battery and the recording apparatus is formed, and the electric current passes through. The recording apparatus is similar to that used in Morse's telegraph. Attached to clock-work, by which a uniform motion is produced, are two cylinders, between which is carried a strip of paper divided into about 250 longitudinal divisions, — one for each note and stop in the organ. Corresponding to each of these divisions is a magnet, whose armature carries a lever armed with a style, which indents the paper as long as the electric current is passing through. When any note or stop is brought into action, the spring connected with it is pressed down, the circuit is completed, the corresponding armature is attracted to its magnet, and the division of the paper belonging to the note struck is indented with a line proportionate in length to the time during which the note is held down. A staccato touch will be represented by a simple dot, while a longer tone will be recorded by a more prolonged indentation. The clock-work is so geared that the paper is carried forward on the rollers at the rate of about one half an inch per second, thus recording each note in the most rapid playing, at the rate of about ten notes per second by a line one twentieth of an inch in length, and longer notes by lines proportionally extended.

Mu'sic-stool. A stool with a pillar leg, and a revolving seat adjustable as to hight by means of its screw-stem.

Mu'sic-type. Movable types for setting up music to be printed by the ordinary printing-press.

The first plan was that of Cowper, who printed by two operations; the first printing the lines and the second the notes.

The second plan was that of Branston, who punched the notes and cut the lines deeply in a plate and from this obtained a stereotype, from which he printed in the usual manner.

The present plan of detached types was introduced by Hughes of London, about 1840. See pp. 310, 311, of Ringwalt's "Encyclopedia of Printing."

Mu'sic-wire. *a.* A steel wire employed for instruments of wire.

b. Wire drawn of various patterns and used in some kinds of music-printing.

Mu'sic-writ'er. Several contrivances were suggested or made during the last century for "writing extempore voluntaries or other pieces of music, as far as any master shall be able to play them upon the organ, harpsichord," etc. (*Phil. Tran.*, 1747.) Creed invented a machine for this purpose in England in 1747; Hennersdorf of Berlin, one in the following year. John Freke in England, Unger and Hohlfield in Prussia, worked at the idea. Unger formed a part of the harpsichord. The device of Hohlfield was attachable to any instrument. Descriptions were transmitted to the Academy of Berlin in 1752, and published in Brunswick in 1774.

Mus'ket. (*Fire-arms.*) The fire-arm of the infantry soldier. It superseded the arquebus, on which it was an improvement. Formerly, smooth-bore and muzzle-loading, modern progress has improved it into the rifled breech-loader of the present. See FIRE-ARMS.

Mus'ket-oon. A short musket used by cavalry and artillery previous to the introduction of breech-loaders.

Mus'lin. (*Fabric.*) A bleached or unbleached thin white cotton cloth, unprinted and undyed; finer than calico. Varieties are known as Swiss, buke, mull, jaconet, lawn, saccharilla, harness, leno, nainsook, seerhand, foundation, cambric, cord, check, figured, long-cloth, tamboured, muslinet, organdie.

Muslins are so called from Moussol in India. First imported into England in 1670. Made in England, 1778–80. Other very different styles of fabric are now indifferently called muslins, and the term is

Digitized by Google

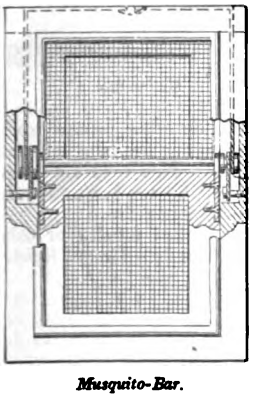
used differently on the respective sides of the Atlantic.

At the London Exhibition in 1862, a few yards of English muslin were shown, woven from a thread .00216 of an inch in diameter, but the finest Dacca thread is only one quarter the size; and there is this essential difference, that the finest European muslins have little or no durability, whereas the Dacca muslins, of far finer quality, are strong and lasting. This is in part explained by the fact that the thread of the India fabric, being made by hand, is more closely twisted and compressed, — the number of twists to an inch in the best English being 68.8; the Indian, 110.1.

One pound of the finest Dacca thread is 250 miles in length. The most delicate pieces are transported in bamboo reeds, and a tube eighteen inches long and one inch in diameter will hold twenty-two square yards. One of the best pieces which found its way to England was ten yards long by one yard wide, weighed only three ounces two pennyweights, and could be passed through a very small ring. A Persian ambassador to India, on his return to his native country, once presented the king with a cocoa-nut-shell containing a turban sash sixty cubits long. The warp threads, in the best qualities, number from 1,000 to 1,800 in a piece one yard wide. Four square yards of some specimens weigh only 566 grains. The Emperor Aurungzebe reproved his daughter because, on a certain court occasion, the outline of her form could be distinctly seen through her dress. Her defense was that her covering consisted of seven garments.

To the fine and delicate Indian muslins the names of "webs of woven air," "dew of night," "running waters," etc., are given by the natives. They use the spinning-wheel generally for the ordinary fabrics, but the spindle still holds its place in the hands of the Hindoo woman when employed in spinning thread for the finer muslins. For these the Hindoo woman first cards her cotton with the jawbone of the *boa'ee* fish; she then separates the seeds by means of a small iron roller worked backwards and forwards upon a flat board. An equally small bow is used for bringing it to the state of a downy fleece, which is made up into small rolls to be held in the hand during the process of spinning. The apparatus required for this consists of a delicate iron spindle having a small ball of clay attached to it in order to give it sufficient weight in turning, and imbedded in a little clay there is a piece of hard shell, on which the spindle turns with the least degree of friction.

Fig. 3266.



Musquito-Bar.

Attention is paid to the temperature of the air during the process of spinning, and the spinners in the dry climate of the northwest of India work under ground to secure a moist and uniform atmosphere.

The Hindoo's loom has a yarn-beam, a cloth-beam, heddle, swinging lathe, shuttle with an eye, treddles, and temple.

Mus'lin-de-laine. (*Fabric.*) A cotton chain and woolen filling, or an all-wool ladies' dress-goods, printed like calicoes.

Mus'li-net. (*Fabric.*) A kind of muslin of which there are several varieties, as single-cord, fancy satin-stripes, and figured.

Mus-qui'to-bar. A net to ward off musquitoes, gnats, and other flying insects. It is usually a canopy which surrounds the bed, but is sometimes applied to the windows and doors to exclude outdoor insects from a room.

In the example, it is applied to a window. The cords are attached to screws fixed to the casing, and are passed once around the pulleys, so that the act of raising or lowering the sash revolves the roller and rolls up or unrolls the bar or netting.

Mus-qui'to-can'o-py. A netting acting as a protection against musquitoes.

The *conopeum*, or musquito-bar, is mentioned by Horace. It was of linen thread, of a gauze texture. Its name is literally rendered, *gnat-curtain*, and survives in our word *canopy*.

It is usually supported upon a tester or canopy, and depends all around the bedstead. In Fig. 3267 it is upheld by a frame laterally expansible, and its parts detachable so as to be attached to any bedstead, or packed in a trunk.

Fig. 3267.

Musquito-Net.

In Fig. 3268 the cot-bed is supported on springs, and the musquito-netting supported by attachment to a wall and a foot-rest.

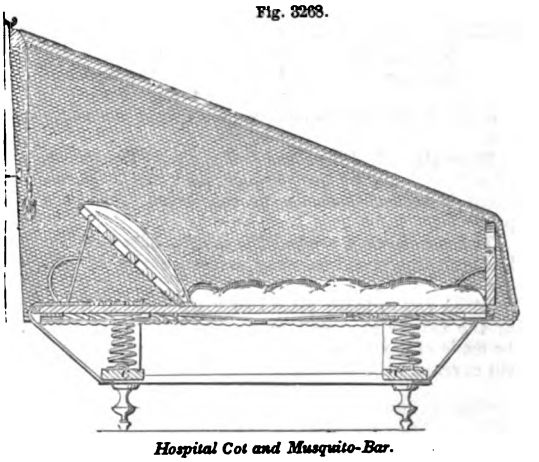
Fig. 3269 has a calash-top.

Mus'role. (*Menage.*) The noseband of a bridle.

Mute. A device to deaden the sound of a musical instrument, wind or stringed.

a. Fig. 3270 is an example of one applied to the pavilion of a horn. A plug is made to fit the bell of the instrument, and has a central tube, which allows only a part of the sound to issue. By this means the sound is

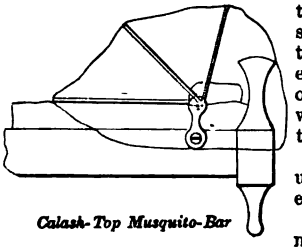
Fig. 3268.



Hospital Cot and Musquito-Bar.

Digitized by Google

Fig. 3269.



Calash-Top Musquito-Bar

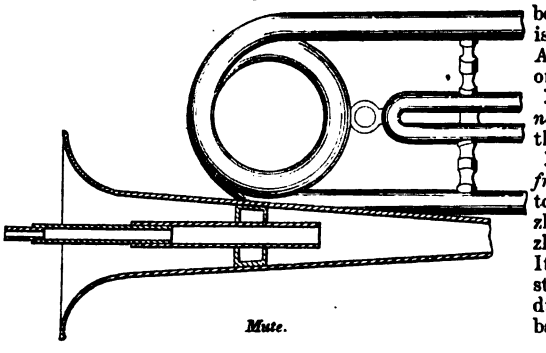
deadened, without throwing the instrument out of tune, and pupils are enabled to practice on the instrument without annoying their neighbors.

The mute is also used to produce echo effects.

b. A little implement placed on the bridge of a stringed instrument to deaden its sonorousness, and give it a mournful sound. A *sordine.*

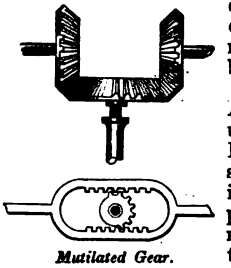
Mu'ti-la-ted Wheel. A wheel, from a part of the perimeter of which the cogs are removed. It is usually adapted to rotate constantly in one direction, and impart an intermittent motion to other cog-wheels or a reciprocating motion to a rack-bar, by alternate connections to one or the other of said wheels, or the respective racks of the bar.

Fig. 3270.



Mute.

Fig. 3271.



Mutilated Gear.

Mu'tule. (*Architecture.*) A projecting block worked under the corona of the Doric cornice, in the same situation as the modillions in the Corinthian and Composite orders; it is often made to slope downward toward the most prominent part, and has usually a number of small guttæ or drops worked on the under side.

Muz'zle. 1. (*Guns and Ordnance.*) The mouth of a gun, closed by the *tompion*, and, in ships, secured by *muzzle-lashings* to the upper part of a port.

The *muzzle-ring*, around the mouth of a cannon, has been suppressed in many modern styles of ordnance.

2. A gag or mask placed over the head of a dog or the muzzle of a calf or vicious horse. It may be made of heavy leather, galvanized wire, or block-tin covered with leather.

One of the heaviest descriptions of muzzles was used upon the untamed "Cruiser" before he was made tractable by Mr. Rarey. The illustration shows the muzzle and halter; the former was of iron and leather, a bar passing in front of the lips which compelled him to lick up his food.

Fig. 3272.

"Cruiser" Muzzled.

Fig. 3273 is a muzzle to prevent biting the manger, but allow the horse to pick hay.

3. The piece at the forward end of the plow-beam by which the draft is attached. The *clevis.* Also called the *bridle*, or the *plow-head.*

Fig. 3273.

Crib-Biter's Muzzle.

Muz'zle-cap. (*Ordnance.*) The cover over the muzzle of a gun.

Muz'zle-sight. The *front-sight*, screwed into the swell of the muzzle of a gun or the muzzle-band of a howitzer. It is made of iron or steel, and is equal in hight to the *dispart* or difference between the semi-diameters of the base-ring and muzzle.

Muz'zle-stop'per. (*Ordnance.*) A *tompion*, to close the mouth of a gun.

Muz'zle-strap. (*Menage.*) A broad strap, which is buckled around the horse's mouth to prevent his biting; used in place of a muzzle.

My'o-dyn'a-mom'e-ter. An instrument for measuring the strength of the muscles.

Myr'i-o-ra'ma. An exhibitional picture made of a number of separate sections which are capable of being associated in various ways so as to form distinct scenes.

Myr'i-o-scope'. This is a variation of the kaleidoscope, and, like the latter, depends upon the multiplication of images, which coalesce in such manner as to form a geometrical pattern.

Fig. 3274.

Myrioscope.

A square box has a sight-hole in front, and at the rear are two plane mirrors which are arranged at a suitable angle. On horizontal rollers is a piece of embroidered silk or other ornate fabric, which is caused to traverse by means of a crank-handle on one of the rollers. This causes a pretty display when the ornamental figures are multiplied and thrown into geometrical apposition.

The top of the box is of oiled muslin or other translucent material which admits sufficient light.

N.

Nab. 1. (*Fire-arm.*) The cock of a gun-lock.
2. (*Locksmithing.*) The keeper of a door-lock.

Nac'a-rat. (*Fabric.*) Fine linen or crape dyed of a pale red color.

Nail. 1. A sharp narrow piece of metal for attaching objects by driving it into or through them. It differs from a *spike* or a *tack* in being smaller than one and larger than the other; from a *screw* in that the latter is not driven but twisted into the wood; from a brad in having a head, while the *brad* has but a spur.

The *nail* used by Jael, the wife of Heber the Kenite, when she smote Sisera, was a tent-pin (*vated*). The hammer was the mallet used to drive in the tent-pin. The nail was probably of hard wood, and when "fastened in a sure place" was useful then as now. It is not all ground that will hold a tent-pin securely when a wind-storm comes on. Deborah's song is a magnificent pæan, but we must agree with Kitto that Jael's was "a treacherous and cruel act."

The nails of ancient Egypt were usually of bronze. Iron nails have mostly perished with rust.

The tools of the Tahitians, when first discovered, were made of stone, bone, shell, or wood. They had no idea of metal. When they first obtained nails, they mistook them for the young shoots of some very hard wood, and, hoping that life might not be quite extinct, planted a number of them carefully in their gardens. Eight years after the first voyage of Captain Cook, that distinguished navigator says iron had quite superseded stone and bone.

Until eighty years since nails were always forged. Before the introduction of machine-made nails, 60,000 persons were employed in forging nails in Birmingham, England.

One authority states that there are about 300 varieties of nails made in England, and 10 sizes of each variety. We have no such to present.

The English mode of numbering, 7 lb., 8 lb., etc., denotes that 1,000 of the respective varieties would have those weights.

This mode of enumeration is substantially similar to our own, but much variation has occurred.

The following are the names, lengths, and number to the pound of the several sizes of nails: —

Name.	Inches long.	No. to the pound
2*d.* fine	1	880
3*d.* fine	1¼	665
3*d.* common	1¼	400
4*d.*	1½	280
5*d.*	1¾	195
6*d.* common	2	155
6*d.* fencing	2	80
7*d.* common	2¼	120
7*d.* fencing	2¼	65
8*d.* common	2½	90
8*d.* fencing	2½	50
9*d.* common	2¾	70
9*d.* fencing	2¾	40
10*d.* common	3	55
10*d.* fencing	3	30
12*d.*	3½	45
16*d.*	3½	28
20*d.*	4	20
30*d.*	4½	16

Nails are cast for some purposes, but their quality is inferior. They may be improved by ANNEALING (which see).

Garden nails for driving into brick walls, and nails for shoe-soles, are cast.

In 1718 an English patent was granted to Clement Dawbeny for cutting iron into nail-rods; it was worked by water-power.

Clifford, 1790 (England), patented a process of making nails by swaging between rollers whose depressions agreed with the shape of the nail; half in each roller. The heads and tails joined so as to make them in a string, to be afterward separated by nippers. It was proposed to treat a sheet in this way, converting it into strings of nails.

Clifford's next machine was to cut the nails from a bar rolled thicker at the head-end. The nails were made at another operation, in a swage.

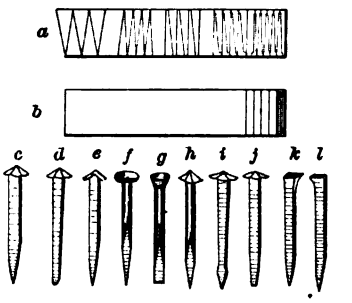
Thirty or forty patents in England followed these of Clifford's, but the American nail-cutter was the first to cut the nails and swage the heads at one operation. See NAIL-MAKING MACHINE.

The preliminary operations of smelting, puddling, squeezing, rolling, cutting, fagoting, re-heating, and re-rolling in the nail-plate train are described under their appropriate heads. The plate thus prepared is taken to the cutting-machine, which shears off pieces as long as the width of the plate, the strips having a width to suit the particular size of nail for which they are intended. This is a little longer than the destined nail, as a part of the slip cut from it is to be upset to form the head. The nail-strips are heated by being placed on their edges on red-hot coals, whence they are taken one by one by the pinchers of the boy who tends the nail-machine.

It will be understood that the plate as it comes from the nail-plate train has fibers running in the direction of its length. This is cut transversely into strips in which the fibers run across. A transverse cut on this strip gives a nail in which the fibers are lengthwise. See diagram *b*.

The cutting jaws of the nail-machine are presented somewhat obliquely to the line of direction of the nail-plate, so as to remove a taper piece, the wide end being swaged into a head and the sharper end remaining as a point, and the nail-plate being turned over after each cut.

Fig. 3275.



Nail-Plate and Nails.

Sparables, sprigs, brads without heads, and glazier's points are all of them of a triangular shape, and are merely cut from the strip. Brads with heads and headed nails are made by cutters of peculiar form, which leave projections upon the head-ends of each nail, as seen in the figure, which illustrates the various kinds mentioned.

Nails are assorted as to —

1. *Purpose;* as, *hurdle, pail, deck, scupper, sheathing, fencing, slating.*
2. *Form of the heads;* as, *rose, clasp, diamond, billed, clout, countersink, dog,* etc.
3. *Form of points;* as, *flat, sharp, spear, clinch.*
4. *Thickness;* as, *fine, bastard, strong.*

Digitized by Google

5. *Size;* from 1½ lb. to 40 lbs. That is, 1,000 nails of a given size will weigh so many pounds.

6. *Material;* as, *copper* nail, for sheathing of ships, metal covering of roofs. *Galvanized*, plated with zinc, etc.

7. *Mode of manufacture;* as, *wrought, cut, cast.*

The accompanying cut shows some of the peculiarities as to *heads, points,* and thickness.

c. Rose-nail; sharp point, a flat head showing facets, square shank.
d. Rose-nail; flat point, square shank.
e. Clasp-nail; bastard (medium) thickness, barbed head, square shank.
f. Clout-nail; fine point, flat circular head, and round shank.
g. Countersunk nail; countersunk head, flat point, round shank.
h. Dog-nail; faceted head, round shank, fine point.
i. Kent-hurdle nail; a broad, thin, rose head, flat shank, spear-point for clinching.
j. Rose-clinch nail; rose head, square point, either clinched or riveted down on a washer or *rove*.
k. Horseshoe-nail; countersunk head, square shank, fine point.
l. Brad; billed head, square shank, fine point.
To which may be added *spikes, tacks*, and other varieties.

Nichol's nail (1873) is a strong, light nail formed of sheet-metal with or without a head, and stiffened by longitudinal grooves, ridges, or corrugations.

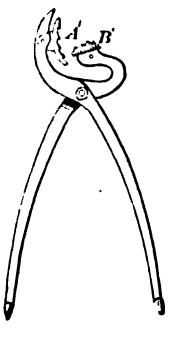
See under the following heads: —

Bastard-nail.	Nailer's forge.
Brad.	Nail-hammer.
Brob.	Nail-machine.
Bullen-nail.	Nail-plate feeder.
Clamp-nail.	Pail-nail
Clasp-nail.	Picture-nail.
Clinch-nail.	Plensbing-nail.
Clout-nail	Ribbing-nail.
Counterclast-nail.	Rose-nail
Countersink-nail.	Screw.
Cut-nail.	Screw-nail.
Deck-nail.	Scupper-nail.
Diamond-nail.	Sharp nail.
Dog.	Sheathing-nail.
Door-nail	Sparable.
Doubling-nail.	Spear-nail.
Fencing-nail.	Spike.
Fine nail.	Spike-extractor.
Flat-head nail.	Spike-machine.
Flat nail.	Sprig.
Forge.	Tack.
Frost-nail	Tack-claw.
Garden-nail.	Tack-driver.
Gate-nail.	Tack-hammer.
Gimp-nail.	Tack-puller.
Glazier's point.	Tin-tack.
Hob-nail.	Tree-nail.
Horseshoe-nail.	Trunk-nail.
Hurdle-nail.	Weight-nail.
Lead-nail.	Wheelwright's nail.
Mop-nail.	Wire-nail.
Nail-clincher.	

2. (*Blasting.*) A taper copper rod used in tamping to make a hole by which the fuse or train may reach the charge.

3. A stamping instrument.

Fig. 3276.



Nail-Clincher.

Fig. 3277.

Nail-Driver.

4. A measurer of length, 2¼ inches = ⅛ of a yard.

Nail-ball. (*Ordnance.*) An iron ball with a tail-pin projecting from it, to keep it from turning in the bore of the piece.

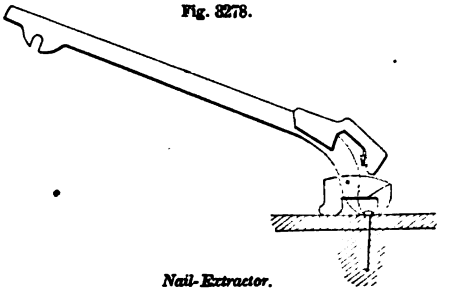
Nail-brush. A small brush for cleaning the finger-nails.

Nail-clinch'er. A blacksmith's tool for clinching the point end of a nail, — or what remains of it — against the hoof. In the example, the steel faces of the clincher are adjustable, being hinged to the jaws so as to conform to the various forms of hoofs, one face *B'* resting below the shoe and the other *A'* clinching the nail.

Nail-driv'er. In Fig. 3277, the point of the instrument is placed at the spot where the nail is to be driven, the plunger is raised, and a nail dropped through the feed-tube; the plunger being then allowed to fall drives the nail home.

Nail-ex-tract'or. An implement with nipping claws for grasping a nail and withdrawing it. In the example, one claw is upon the fulcrum-piece to which the other jaw is hinged.

Fig. 3278.



Nail-Extractor.

In Fig. 3279 the lever and fulcrum are pivoted together, and their jaws are clamped together by the act of lifting.

Fig. 3279.

Nail-Extractor.

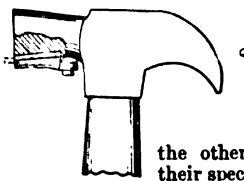
Nail-file. A small, flat, single-cut file for trimming the finger-nails. It is a part of the furniture of the dressing-case, or is cut on the blades of the nail-scissors, or on one small blade of a pocket-knife.

Nail-ham'mer. One for driving nails.

Notably, one which holds a nail for driving, as in the example.

Between the *peen* and the claws is a recess in which a nail may be held to start it in the lumber; the other parts are effective for their specific duties.

Fig. 3280.



Nail-Hammer.

Fig. 3281.

Nail-Hammer.

In Fig. 3280 the nail is gently held by the spring under the poll of the hammer till it is stuck into place ready for driving by a one-armed carpenter.

Nail-head Tool. (*Iron-turning.*) A lathe-tool *a* having a circular expansion with a sharp edge, causing it to resemble, in a degree, a nail-head. One edge is supported on the rest *b*, and the other is applied to the work to be turned.

Fig. 3282.

Nail-Head Tool.

Nail'ing-ma-chine'. 1. (*Carpentry.*) A machine in which, the parts of a box being placed in the

Digitized by Google

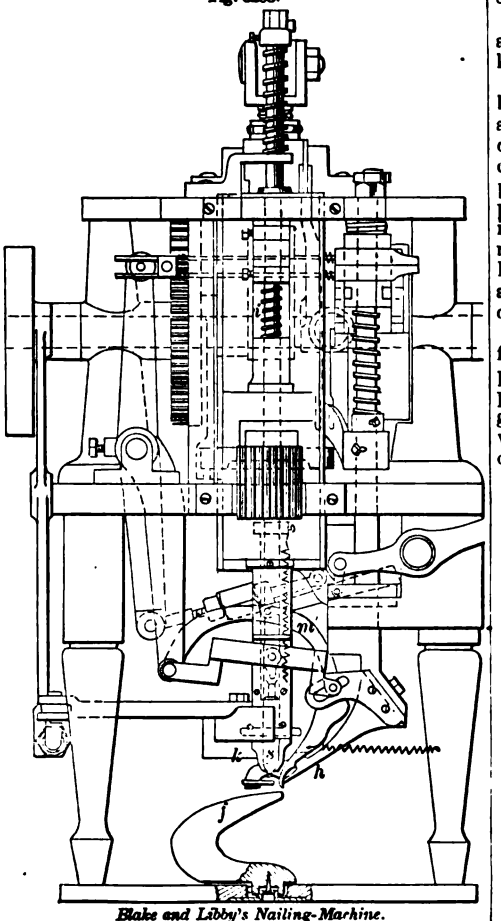
proper relation, plungers advance and drive the nails which secure the sides of the box together, and the sides to the bottom.

Similar machines (see Rice's and Holmes's patents) are used for driving the legs of a wash-board against the sharpened edges of the corrugated zinc plate, sinking the zinc into the legs; an immediately succeeding motion forces the nails which secure the legs to the other portions. The nails are fed into grooves from hoppers, and the drivers advance along the grooves and complete the operation.

2. (*Shoemaking.*) A machine which acts automatically to drive the nails into shoe-soles. The nails are fed from a hopper, or are cut, one at a time as needed, from a coil of wire, and driven into the sole.

In Fig. 3283, the work is held for nailing between the presser-foot *h* and horn *f*. At the lower part of

Fig. 3283.



Blake and Libby's Nailing-Machine.

the nail-tube *i* is suspended a pivoted guide *s*, which is vibrated so as to be in line with the tube for receiving a nail and to form an angle therewith when the nail is driven. The nail-tube is turned half round at the moment of driving, so that each nail is driven into the work inclined oppositely to the preceding one. The tube *i* and nail-driver are reciprocated by an eccentric on the driving-shaft, the other motions being derived from cams on the same shaft. The presser-foot arm is adjustable on the arc *m'* to regulate the feed of the work, and devices connected with the presser-foot are provided, by which the motion of the driver-bar is adjusted to varying thickness of the work.

The mechanism by which the nails are cut from the continuous coil of wire is adjustable, so that each nail may be allowed to project entirely through the inner sole and have its end clinched on the horn, or may only penetrate sufficiently to unite the work. The nailing mechanism and presser-foot may each be lifted away from the horn by means of a lever, when it is desired to remove the work.

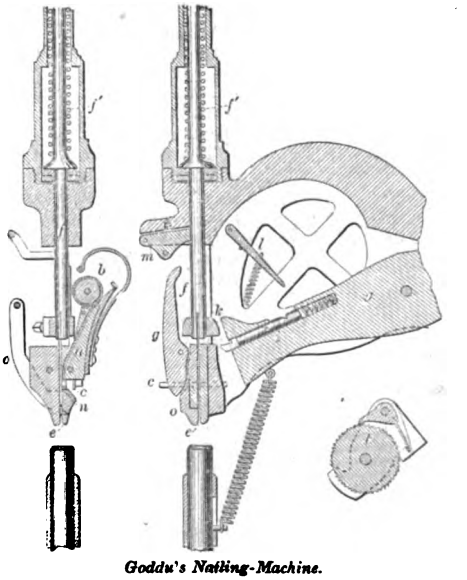
In Goddu's machine (Fig. 3284), for nailing shoe-soles with wire, the wire from a reel is fed downward through a tubular opening in the guide *a* by a feed-wheel *b* advanced by means of a ratchet and pawl. It is severed by a cutter *c* on the upright lever and a stationary cutter, and driven by a nail-driver *e* fixed in the lower part of the vertical shaft *f*.

The lever *g* is operated by depressing a treadle acting against the force of a spring which tends to keep that end in elevated position.

Its upward movement causes the spring-catch *i* to bear against the foot *k* of the nail-driver carrier *f*, and lift it until the arm *l* engages a notch in the spring-catch, retracting the catch and allowing the nail-driver carrier to be acted on by its spring *f'*. A pivoted clamp or binder *m* bears against the carrier, preventing its descent until an arm on the binder is struck by the lever *g* at the end of its upward movement, so that no feed will take place unless the lever is sufficiently raised, the feed-wheel ratchet and pawl being operated by the downward motion of the carrier *f*.

The wire from the feed-guide being severed by the fixed and stationary knives *c' n*, the nail cut off passes into a passage in the transferrer *o*; this is pivoted, and is moved by a stud entering a cam-groove on the lever *g*, so as to present the nail in vertical position at the proper moment to be acted on by the driver.

Fig. 3284.



Goddu's Nailing-Machine.

See also patent of Tyson, March 24, 1874, for screwing the uppers upon the soles and heels of boots.

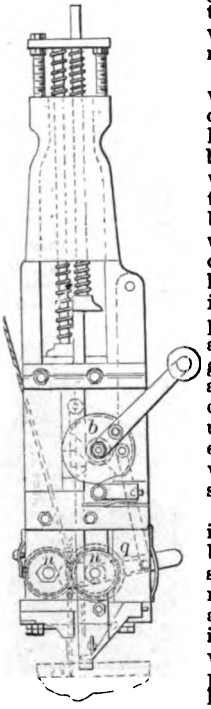
Digitized by Google

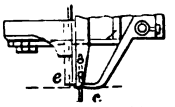
The jack or work-supporting mechanism is mounted on a shaft in the tubular standard *p*, connected by a spring with the lever *g*, so as to be drawn up to the nose-piece *q* when a nail is to be driven.

In Caralli's machine two wires from separate reels are simultaneously fed through two tubes, by which they are conducted to a plate having dies through which they are passed, being at the same time rotated by bevel-gearing, by which screw-threads are cut upon them. As they are screwed into the work, held by mechanism on an arm projecting from the machine, they are severed by movable jaws acting against stationary cutters and operated by a foot-lever, by which the end next to be inserted is cut with a tapering point to facilitate its penetration.

In Prosser's machine, wire from a coil is drawn between a pair of serrated rollers which indent it and also press it into a hole previously punctured by an awl. It is then severed by a pair of shears. The rollers are intermittingly advanced by a ratchet and pawl actuated by a cam on a vertically reciprocating rod, which also operates a lever that depresses the awl and opens and closes the shears. One arm of the shears carries a pawl engaging a ratchet-wheel which turns a wheel by which the work is advanced beneath the nailing mechanism.

Fig. 3285.





Sargeant's Nailing-Machine.

In Fig. 3285, the cam-wheel *b*, through the medium of a rod and pivoted lever *q*, lifts the feed-foot *c*, which, being released, is swung forward by a spring, advancing the work the due interval between two nails. The cam-wheel *b* also raises the awl-driver, the shaft of which has a cam that lifts the driving-bar *e*, and also operates a pawl intermittingly turning a ratchet by which the two geared wire feed-wheels *n n* are rotated. The awl and peg-driver carriers are consecutively released at the proper moments and forced downward by springs on their respective shafts.

The wire drawn from a coil is severed into proper lengths by a cutter operated from the swing-bar *q* by means of a ratchet-wheel and pawl, with an adjusting device for varying the number of teeth advanced at one stroke of the pawl so as to cut different lengths of wire.

Nail-making Machine. Nails were formerly forged from the bar, which was reduced by hand to the proper size. In 1606, Sir Davis Bulmer obtained letters-patent for a machine for cutting nail-rods by water-power. The details of his invention are unknown, no records of English patents prior to 1617 existing.

In 1618, Clement Dawbeny patented an improvement on Bulmer's machine, its object being to remedy "the waste that comonly grewe and happened of the iron which was usually cutt into the said small rodd by reason of the often heating, vnapt instruments, and devises then vsed and practised for the cutting thereof." No farther description is given.

Neither of these appear to have been brought into practical use, and were probably soon forgotten.

Machinery for splitting rods for nail-making was first introduced in Sweden. The mode of construction and operation was ascertained by a man named Foley, of Stourbridge, England, who traveled to Sweden and fiddled his way into the affections of the workmen at the mills, where he took mental notes of the machinery and brought them to England, where he established a factory.

In July, 1790, Thomas Clifford patented in England a machine for making nails from the prepared rod by drawing it between rollers having cavities corresponding to the shape of the nail; and in December of the same year he patented a process for drawing bars or plates to a varying thickness and cutting the nails therefrom by a punch. Machines of this kind were in operation at French's factory, Wineburne, Staffordshire, England, in 1792.

Cut-nails were first made in this country.

About 1775, Jeremiah Wilkinson of Cumberland, R. I., cut tacks from plates of sheet-metal, and afterward made nails and spikes in a similar manner, forming the heads in a vise.

Ezekiel Reed of Bridgewater, Mass., in 1786, invented a machine for cutting nails from the plate, and in 1798 obtained a patent for cutting and heading them at one operation. Benjamin Cochran had also constructed a machine of this kind; and Josiah Person of New York, in 1794, patented a machine for cutting nails from the sheet.

Perkins's machine, invented 1790 and patented in 1795, is said to have been capable of making 200,000 nails per day.

These, and Odiorne's, which embraced some improvements upon them, attracted great attention in England, where they soon came into extensive use.

At the close of the century, 23 patents had been granted for improvements in nail-machines.

In cutting nails from the plate, it is an object of primary importance to avoid waste of metal. This is effected either by rotating the plate 180°, or by changing the angle of the cutter at each stroke, cut-nails universally being made slightly tapering in one direction. For this purpose many varying forms of feeding-device have been invented, a few of which are illustrated.

Fig. 3286.

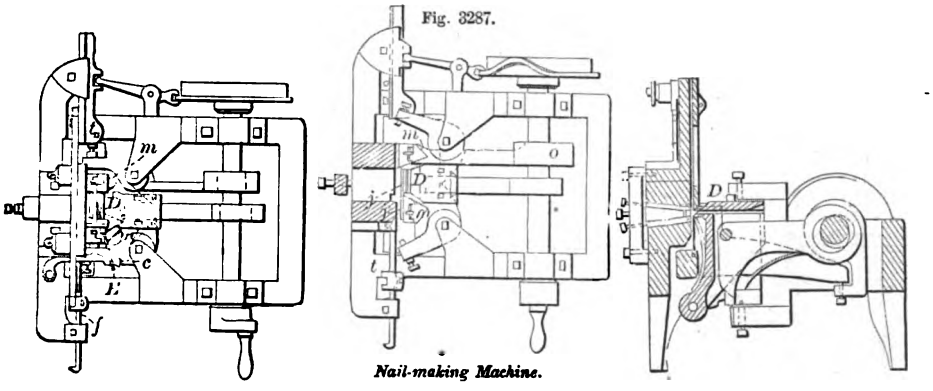
Nail-making Machine.

Digitized by Google

In Fig. 3286 the feeding is done by hand, the plate being turned by the operator. A lever operated by an eccentric on the shaft works the cutter inclosed in the box *a*, forming the nail-blank, which is then moved sideways and presented to the action of the lever *b*, by which the head is formed.

In the machine (Fig. 3287), two nails are cut from the sheet at once. On the forward movement of

Fig. 3287.



Nail-making Machine.

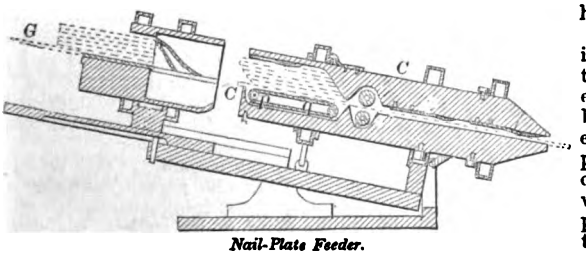
the punch *D* a projection is made to come in contact with an inclined block on the spring *E*, so as to force the latter against the blank while the punch is operating. The spring is held in position by a locking lever *c* until the punch is withdrawn, when a reciprocating stud *f* comes in contact with an arm on the locking lever and releases the spring. The fingers *j j'* which push the blanks between the grippers are held in reciprocating boxes *t* by springs, so as to slide if any undue resistance is met. The grippers *m m'* hold the cut blanks in position with the large ends projecting far enough for the headers to form the heads.

The illustration shows two plan views in different positions of the parts, and also a vertical longitudinal section.

In Fig. 3288, the nail-plates are placed in a box *G*, from which they are delivered to the hollow cylinder *C C*, and fed forward singly by the band-carrying rollers *p q* to the cutters. The cylinder is, by means of gears, moved half round after each cut, being withdrawn from the cutters by a cam movement.

In Fig. 3289, the nail-blanks, previously headed, are fed to the upper pair of rolls, which reduce the size of the body. The head is then seized by the second pair, arranged transversely to the first, by which it is still farther reduced, and so on successively, until the last pair, by which the nail is perfected, is reached. Each pair is grooved to correspond with the intended form of the nail, the grooves successively decreasing in size from first to last. The successive pairs of rollers act upon alternate faces, the rolls *a a*, etc., being at right angles to their alternates.

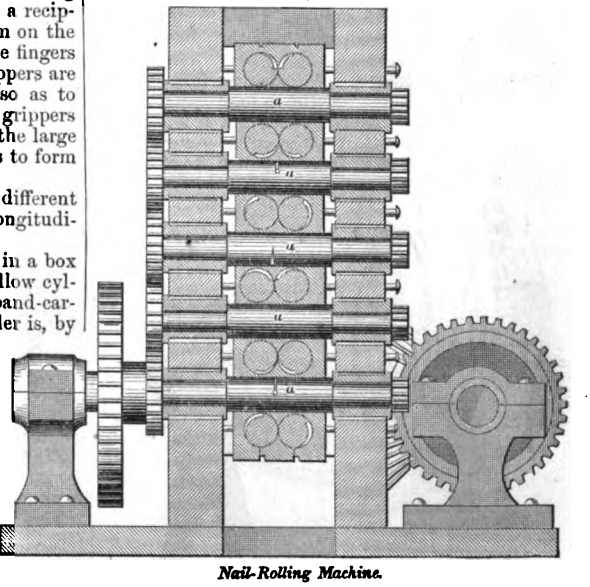
Fig. 3288.



Nail-Plate Feeder.

Wickersham's nail-machine produces a nail pointed like a chisel and tapered throughout its whole length. A sheet of metal from 20 to 25 inches wide presents its edge to a series of cutters arranged around the periphery of a cylinder which cut simultaneously a row of nails from the entire edge of the sheet. The nails are cut and headed at one operation.

Fig. 3289.

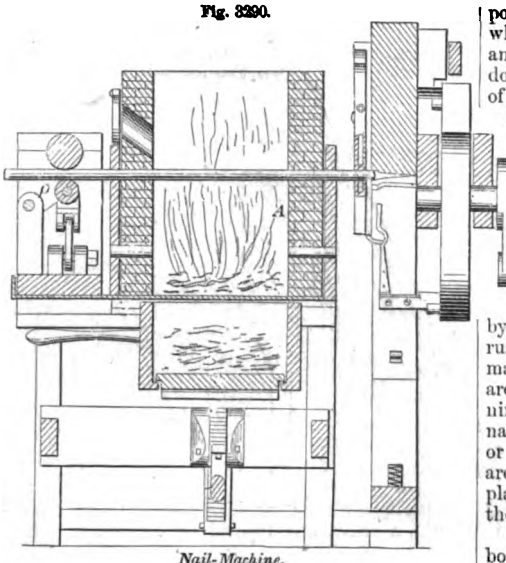


Nail-Rolling Machine.

In Ward's machine (Fig. 3290), for making horseshoe or other wrought-iron nails, the rod *p* is automatically drawn by rollers through the furnace *A*, where it is brought to a forging heat, and is presented to the action of hammers while supported by an anvil. The hammers are operated by crank-arms and levers, which withdraw them from the iron, and at the proper moment permit springs to act upon them, forcing their acting faces, which

Digitized by Google

Fig. 3290.

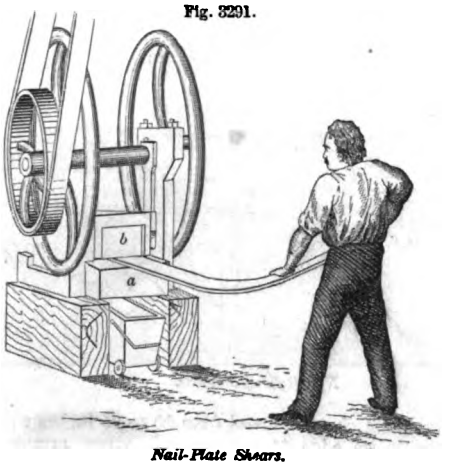


Nail-Machine.

are grooved to suit the shape of the nail, into contact with the red-hot rod, which is thus hammered on all four sides at once.

Nail-plate Shears. A machine for cutting nail-plates into suitable lengths to form nails. The plate is laid on the cutter-block *a*, and fed forward at each upward movement of the cutter *b* a distance equal to the length of the nail to be cut, from 2 *d.* to 60 *d.*

Fig. 3291.



Nail-Plate Shears.

The cutter is reciprocated in grooves in the standard by crank attachment to the fly-wheel, its downward movement taking off a slip from the end of the plate. The strip is received in a small car beneath.

Nail-scis'sors. Small scissors having files on the sides and used for trimming the finger-nails.

Nain-sook'. (*Fabric.*) A thick sort of jaconet muslin, plain or striped, formerly made in India. — WEBSTER.

Na'ked Floor'ing. The parallel floor-joists, unboarded.

Na'ker. (*Music.*) A kind of kettle-drum.

Nan-keen'. Originally a fabric made from cotton of a yellow color (*gossypium religiosum*) and exported from Nankin, China. It is now made of white cotton, dyed by oak bark, arnotto, alum, etc., and sent from England to China. A part is, no doubt, reshipped in curious packages with the name of Li upon it.

Nap. 1. The pile of cloth.

2. The down of a hat.

3. *Naps.* The loops of velvet which are cut to make the pile.

Naph'tha-line. A substance formed during the destructive distillation of pit-coal.

Naph'tha-liz'ing. The enriching of poor gas, or carbureting of air, by passing either through naphtha or coal-oil.

Na'pier's Bones. Instruments invented by Napier for performing some of the fundamental rules of arithmetic by a mechanical process. They may be made of bone, ivory, horn, or wood. There are five of them, and the face of each is divided into nine equal parts, each being subdivided by a diagonal line into two triangles. In these compartments or squares the numbers of the multiplication-table are inserted, the units or right-hand figures being placed in the right-hand triangles, and the tens in the left.

"Jonas Moore tells me the mighty use of Napier's bones, so that I will have a pair presently." — PEPYS'S *Diary*, 1667.

They were first described by the inventor, John, Lord Napier of Murcheston, in his "Rabdologiæ seu Numerationes per virgulas, Libri duo," ed. 1617.

"A moon dial, with Napier's bones,
And several constellation stones."
HUDIBRAS.

Na'pier's Com'pass. A draftsman's compass, to one leg of which is pivoted a plain point and pencil-holder, and to the other a plain point and pen. These fold in between the legs, so that the instrument may be carried in the pocket without inconvenience.

Fig. 3292.

Napier's Compass.

Nap'ping. (*Hat-making.*) A sheet of partially felted fur in a stage between the operation of the bow, which first distributes the fur in a light layer, and the *battery* at which it is united to the hat-body. It becomes the *nap* of the hat, which is raised by *carding* and shorn to a length.

Nap'ping-ma-chine'. A machine for raising the nap or pile on woolen and cotton fabrics.

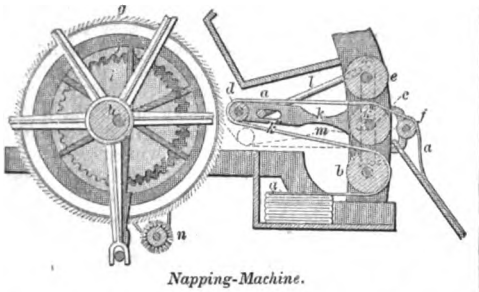
Fig. 3293 illustrates an improved form. In this the cloth *a a a* is drawn between the rollers *b c*, passing around the roller *d*, then between the rollers *c e*, and over the small roller *f* to a receptacle. These rollers, as well as the napping-cylinder *g*, are driven by the shaft *h*, which carries two eccentrics running loose upon it. The inner one of these is attached to the gear-wheel *i* on the napping-cylinder, which meshes with the internal gear *j*, causing an intermittent rotary motion. This movement causes a reciprocating motion of the arm *k* slotted at *k''*, the latter of these slots receiving the pivoted rod *l*, which is adjustably attached to a lever *m* (indicated by dotted lines) provided with a spring-pawl that engages with teeth on the central roller *c*.

In the operation of the machine, at each revolution of the driving-shaft the napping-cylinder is moved slightly forward, remaining momentarily stationary while the roller *d*, which presents the cloth to the napping-cards or teasels on the periphery

Digitized by Google

g, is moved eccentrically back and forth toward and from them, the ratchet device causing at the same

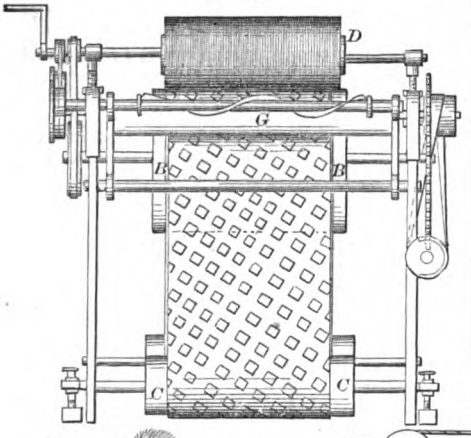
Fig. 3293.

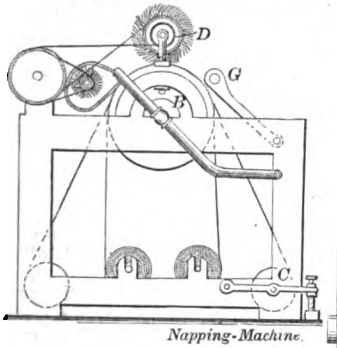


Napping-Machine.

time a partial revolution of the roller *c*, and presenting to the action of the cards a width of cloth equal

Fig. 3294.





Napping-Machine.

to that which is at the same moment withdrawn therefrom by the rollers *c e*.

The roller *d* admits of delicate adjustment to regulate the depth of nap raised.

n is a revolving clearer for removing fibers from the napping-cards.

Four series of the rollers are actuated at the same time by the movement of the shaft, so that four pieces of cloth are napped simultaneously.

In Fig. 3294, the rolls *C B* carry an endless band of thin sheet-metal stenciled with figures of any desired pattern. The fabric, which passes between the roller *B* and the endless band, is only exposed to the action of the napping-cards or teasels on the surface of the cylinder *D* at those points where the metal has been removed from the band; consequently, those parts only are napped, the rest of its surface remaining plain.

A shearing-device *G* of the ordinary kind may also be attached to the machine.

Nap-warp. (*Weaving.*) *Pile-warp.* In fustian weaving, the upper warp covering the main warp or nap.

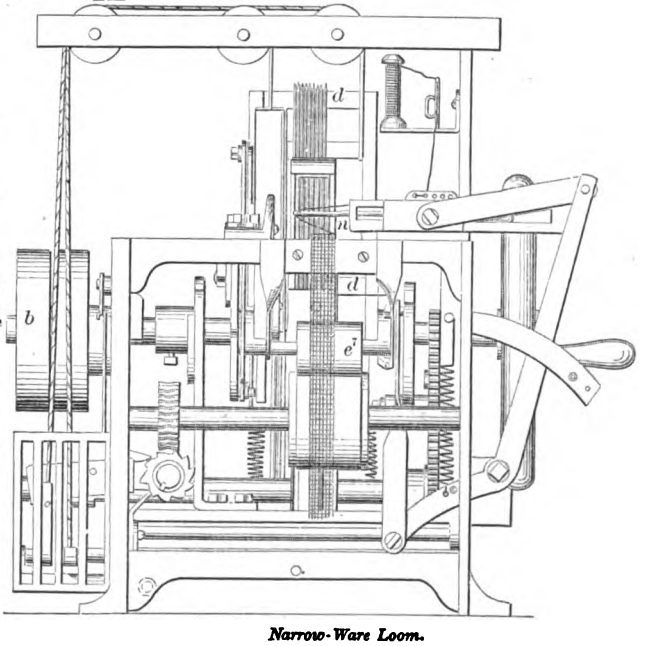
Nar-cot'ic-spray Ap'pa-ra'tus. A device for producing local anæsthesia. It consists of a bottle stopped by a perforated cork, through which passes a double tube, one of whose extremities reaches to the bottom of the bottle. Above the cork, a tube connected with a hollow sphere of india-rubber acting as a bellows penetrates the double tube and communicates through an aperture in the cork with the interior of the vessel. See page 93.

The operation of the bellows causes a current of air to descend through the aperture in the cork last mentioned, forcing the ether or other anæsthetic, with which the bottle is partially filled, to ascend through the inner branch of the tube, at the same time causing a current to pass through the outer tube, driving the ascending fluid before it, and depositing it in the form of spray upon the part under treatment. See ATOMIZER.

Nar'row Cloth. Woolen cloth under 52 inches width.

Nar'row-fab'ric Loom. Or, *narrow-ware* loom. One adapted specifically for weaving ribbons, tapes, bindings, etc. They are sometimes shuttle-looms, but usually have an eye-pointed needle which traverses the shed and back again between each movement of the harness. In the example, the filling-thread is carried double across the shed by a recip-

Fig. 3295.



Narrow-Ware Loom.

Digitized by Google

rocating eye-pointed thread-carrier, and then locked at the opposite selvage by passing a shuttle and its thread through a loop of such filling-thread. The loop is spread by the movement of the thread-carrier across the web.

n is the needle, receiving its weft-thread from the bobbin above. *d d* are the frames of the harness, operated by the cams shown at the lower left-hand corner of the figure. The picker motion is shown at the right, and consists of a bell-crank lever with connections to a cam-wheel and the needle-bar at its respective ends. e^7 and the rollers below it are the take-up. *b* is the band-wheel, through which motion is communicated by a belt from a prime motor. See also NEEDLE-LOOM.

Nar'row Gage. (*Railroad-engineering.*) One less than 4 feet 8½ inches in width between the rails, which is the usual distance between the wheels of locomotives and railroad-cars, as well as those of ordinary vehicles.

Railways of this description have been in operation in the Pennsylvania coal-region for more than thirty years, and have attracted great attention within the past few years, their advocates claiming for them much greater cheapness of construction, both of road and rolling stock, and greater economy of running expenses than can be attained on roads of the ordinary gage. Less excavation and embankment is necessary, a lighter rail is employed, and the cars are made much lighter in proportion to the weight they are capable of transporting. The narrow gages actually in use vary from 3 feet 6 inches to 2 feet.

The Mauch Chunk road has a gage of 3 feet; this, the Nesquehoning, and the Carbondale roads, all narrow gage, were among the first of such gage constructed in this country.

Three feet six inches appears to be a favorite gage, those of Queensland, Australia, India, and Norway being all constructed of this width, the rails weighing from 35 to 40 pounds per yard.

Many engineers advocate a 3-feet gage or one even narrower for some purposes or localities. The narrowest in actual operation, so far as we are aware, only two feet, is the Portmadoc and Festiniog Railway in North Wales, through a very difficult country. This was originally designed as a tramway for the transportation of slate, stone, and other minerals from the hills of Merionethshire to the sea, but has since been used for passengers and general freight.

Fig. 3296 represents an engine, called the "Little Wonder," employed on this road. It weighs 19½ tons, and was first tested by a train 854 feet in length, consisting of 90 slate and 7 passenger cars, weighing 75 tons, constituting in all a load of 94½ tons, which it drew at a speed varying from 14½ to 26¼ miles an hour. Some of the curves on this road have a radius of but 1¾ chains. It is stated that an engine and tender weighing together only 10 tons is also used. The passenger-cars weigh 30 hundredweight each, and carry 12 passengers.

Fig. 3296.

"Little Wonder" (Portmadoc and Festiniog Railway, South Wales).

This is an extreme example. Most of those of more recent date in this country are 3-feet gage. The locomotives and cars are similar in general construction to those employed on wide-gage roads, but much lighter and of greater capacity in proportion to their weight; a four-wheeled house-car on some Western roads weighing 4,000 and carrying 8,000 pounds, and costing $185 to $200. The passenger-cars seat 30 passengers, cost $1,000 and upward, according to style and finish. The locomotives weigh from 8,000 to 12,000 pounds, and cost $4,500 to $7,000. The rail weighs 32 pounds to the yard.

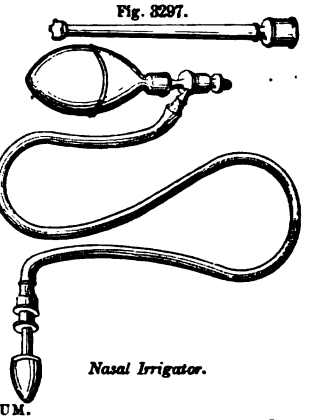
It seems to be conceded that for short roads and those required to accommodate but a moderate amount of traffic, the narrow gage possesses a decided advantage in point of economy, but for long roads transporting a large amount of freight and passengers and requiring high speed, 4 feet 8½ inches is by no means too wide a gage.

Nar'row-ing. (*Knitting.*) Contracting the fabric by throwing two stitches into one.

Nar'thex. (*Architecture.*) The first section in the Roman basilicas, set apart for monks and women, and devoted to certain religious ceremonies.

Na'sal Ir'ri-ga'tor. A syringe for nasal douches. In the illustration, the induction stem is shown detached, and the ejection end has a conoidal nozzle to fit the nostril.

Fig. 3297.



Nasal Irrigator.

Na'sal Spec'u-lum. (*Surgical.*) An instrument for distending the nostrils to expose the mucous membrane of the nose, and enable explorations and operations in cases of polypus, etc. See SPECULUM.

Nas-cale'. (*Surgical.*) A pessary of wool or cotton impregnated with a medicament for introduction into the vagina.

Nat'u-ral Steel. A steel obtained directly from the richer and purer kinds of ore by reducing them with charcoal and refining the cast-iron thus produced, so as to deprive it of a part of its carbon.

It is principally used for making files and other tools.

It is frequently termed German steel, being largely produced in Germany.

Na'ture-print'ing. A process in which impressions which may be printed from are obtained from objects, such as leaves, fibers, lace, etc.

In one method the object, such as a fern frond, is placed between a steel plate and one of heated lead and subjected to a strong pressure, forming an exact intaglio copy in the lead from which impressions are taken. This process was introduced by Auer of Vienna.

Digitized by Google

A process allied to the above consists in the application of successive layers of gutta-percha, — to fossil fishes, for instance, — and a mold obtained, which, being submitted to the action of a voltaic battery, is coated with copper, forming a plate on which all the markings of the fish are obtained in relief, the plate being used to obtain impressions by the ordinary typographic printing process.

By a third method the grain or markings of wood are transferred directly from the wood itself to paper, cotton cloth, etc. The wood is wetted with dilute acid and laid on the material; pressure transfers the markings of the wood to it, and it is then moderately heated, bringing out the colors.

One wetting suffices for twenty or thirty impressions.

Nau-ro-pom'e-ter. (*Nautical.*) An instrument for measuring the amount of a ship's heel or inclination at sea.

Nau'ti-cal A-larm'. See FOG-ALARM; BILGE-WATER ALARM; ICEBERG-ALARM; SHOAL-ALARM.

Nau'ti-cal In'di-ca-tor. An instrument invented and thus named by Hunter.

It consists of a stand supporting a circular plate of polished brass, about 14 inches in diameter, representing the horizon, and marked and numbered accordingly with the proper divisions. The horizon is surmounted by a semicircular plate, as a meridian, set at right angles to the plane of the horizontal plate, properly divided and furnished with an index attached to a nonius indicating minutes. This meridian plate is cut out at the center, to allow room for a pivot or hinge for other parts of the indicator. On one side of the meridian are placed two quadrants, and at the other side one, similarly divided as the meridian and furnished with a similar index and nonius. The quadrants are movable on a pivot or hinge, rising perpendicularly from the center of the horizontal plate, or agreeing to this center; they are singly movable on the pivot, but capable of being attached at any relative distance, and retained in that position by a screw, binding together tails attached for that purpose. To the east and west points of the horizontal plate is attached a horary circle divided into hours, etc. This horary circle represents the path of the sun, and it may be furnished with a nonius, as the other parts are. This circle is so attached to the horizontal plate that it can be moved

Digitized by Google

parallel to it, to suit the sun's declination. This is effected by the circle being attached to two tangent plates, which, by grooves, slide on the projections from the horizontal plate by means of screws passing through and working in these projections, and carrying the tangent plates, and with them the horary circle, to the degree of the sun's declination. This degree is indicated on a scale of tangent divisions on the tangent plates; and as such tangents are of various lengths, an expanding vernier is used to adjust them.

Nau'ti-cal Sig'nals. Signals for affording communication between vessels at sea or between vessels and the shore, consist of a system of flags of various colors for use by day or of lanterns at night, each separate combination and arrangement of which indicates some phrase or sentence that is or may be required in directing the evolutions of a fleet, the movements of a single vessel, making known the wants of the ship which displays it, or in replying to signals made by other parties. A more limited number of signals, sufficing for making known the most pressing necessities and for guiding a vessel into port when unprovided with a pilot, are made by the use of a single flag, attached to a staff, which is waved to the right or left, held vertically, or reversed, to express different meanings.

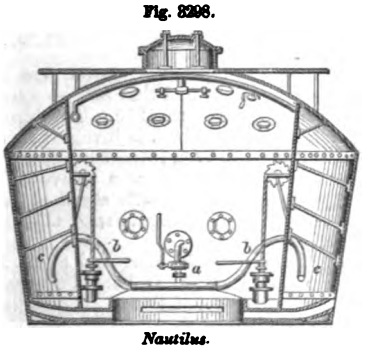
These combinations are depicted in books and numbered, so that, on seeing a particular signal hoisted, a party in possession of a similar book can, by reference thereto, ascertain the number of the signal and its meaning.

Those used by war-vessels differ with each nation, and the books containing them are covered with canvas lined with sheet-lead, so that in case of capture by an enemy they may be thrown overboard and sunk. The code of signals adopted by the British Admiralty requires the use of fifty flags.

For the merchant service the number of combinations required is much less. The code introduced by the late Captain Marryatt, R. N., was in general use until 1857, but is now superseded by that adopted by the British Board of Trade. This requires the use of only eighteen flags, by which 20,000 signals may be made, and numbers up to 70,000 represented. These numbers are printed in a book, and to each a word or sentence is attached.

Nau'ti-lus. A European form of diving-bell. It requires no suspension. Water admitted through

Fig. 3296.



Nautilus.

the cock *a* into the pipes *b b* flows into the exterior chambers *c c*, causing the apparatus to sink. The workmen enter through an aperture at the top, closed by an air-tight cover, and can in still water move the machine in any required direction by stepping on the ground and pushing. Air is condensed in a reservoir at the surface to a degree somewhat greater than the condensation due to the depth, and passes through a pipe into the chambers *c c*, rendering the machine specifically lighter than water and enabling it to lift stones or other objects below. A gage indicates the amount of lifting power attained as the air is admitted, so that the supply may be cut off when the requisite power is attained.

Nau'ti-lus-pro-pel'ler. A device for propelling ships, so named by Mr. Ruthven. A large iron chamber containing water is placed in a suitable part of the ship. This contains a horizontal turbine-wheel rotated by a vertical shaft from the engine. The rotation of the wheel impels the water through two pipes outwardly to each side of the ship, where it escapes through two nozzles which may be directed either toward the stern or bow of the vessel, causing her either to go ahead or back, as the case may be. This motion of the nozzle is rapidly effected by means of a handle on deck. The two nozzles may be pointed in different directions, so as to cause the ship to turn on her center. The motion of the turbine does not require to be reversed, the backward or forward motion of the vessel being entirely controlled from the deck.

The apparatus has been tried by the British Board of Admiralty on the "Water Witch," a vessel of 800 tons. The result was a success so far as a reasonable speed was concerned, but the device was not regarded as equal to the paddle or propeller as a means of propulsion.

The idea is very old, has been tried a number of times, and proposed much more often. See HYDRAULIC PROPELLER.

Nave. 1. (*Vehicle.*) The central portion of a wheel from which the spokes radiate. See HUB.

2. (*Architecture.*) The main body of a church.

Na'vel. (*Ordnance.*) A perforated lug on the under side of a carronade which is engaged by a through bolt and thereby secured to the carriage.

Na'vel-hood. (*Shipwrighting.*) A hood wrought above the exterior opening of a hawse-hole.

Neb'ule-mold'ing. (*Architecture.*) An ornament of the zigzag form, but without angles; it is chiefly found in the remains of Saxon architecture, in the archivolts of doors and windows.

Neck. 1. A narrowed portion of an object relatively near to the end; as of a bottle, an axle.

2. (*Chemistry.*) The beak or rostrum of a retort.

3. (*Ordnance.*) *a.* The part joining the knob of the cascabel to the base of the breech; called the *neck of the cascabel.*

b. The small part of a gun where the chase meets the swell of the muzzle.

4. (*Music.*) The finger-board between the head and the body of a violin, guitar, banjo. Upon the *neck* the strings are pressed by the fingers in playing. Some *necks* have *frets;* the guitar, for instance.

5. (*Architecture.*) The narrow part between the astragal of the column and the annulet of the capital.

6. The jib of a crane.

7. A tubular projection to receive a collar, as that on a stove which receives a pipe.

8. A short shaft.

A diminished portion of a shaft where it rests in the bearing.

9. An intervening and connecting portion; as, the *neck* of a bayonet connecting the *blade* and *socket.*

10. A *goose-neck;* a flexible joint between a hose or pipe and a nozzle.

11. (*Nautical.*) A portion connecting the collar on the yard-arm and the iron of the studding-sail boom.

Digitized by Google

12. The narrower part of an embrasure. The *mouth* is the outer or *wider* part.

13. (*Metallurgy.*) The contracted portion of a furnace between the heating or melting chamber and the *stack*, passing over the *bridge*.

Neck'lace. (*Nautical.*) *a.* A strap round a mast carrying leading-blocks.

b. A chain to which the lower ends of the futtock-shrouds are secured.

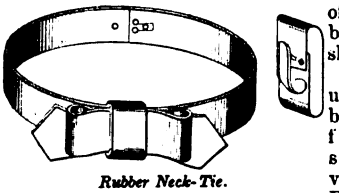
Neck-mold. (*Architecture.*) A small convex molding surrounding a column at the junction of the shaft and capital.

Neck-strap. (*Harness.*) *a.* A strap round the neck of a draft horse; a temporary expedient.

b. A halter strap around the neck. A part of a martingale.

Neck-tie Re-tain'er. A clasp to attach the tie to the neck or to the button of the neck-band of the shirt.

Fig. 3299.

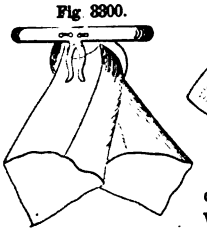


Rubber Neck-Tie.

Neck-ties are usually of ribbon or some fabric, but sometimes of vulcanite, as in Fig. 3299.

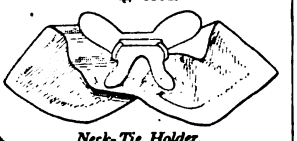
In Fig. 3300, the tie is sewn to an elastic plate, which passes beneath the collar and has a pair of elastic jaws projecting downward from its lower edge to embrace the button.

Fig. 3300.



Neck-Tie Supporter.

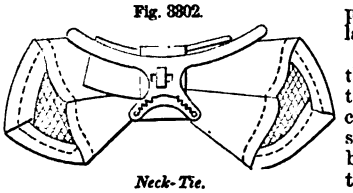
Fig. 3301.



Neck-Tie Holder.

In Fig. 3301, the forks straddle the button attachment, and the wings slip under the lapel of the collar.

Fig. 3302.

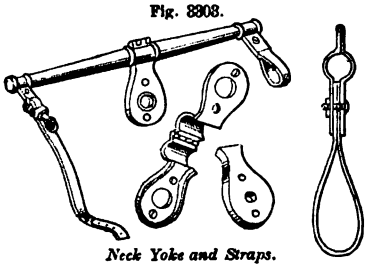


Neck-Tie.

In Fig. 3302, the slotted retainer is secured to the shirt collar or button, and the pin attached to the bow or scarf is caused to interlock therewith.

Neck-twines. (*Weaving.*) In fancy weaving, small strings by which the *mails* are connected with the *compass-board*.

Fig. 3303.



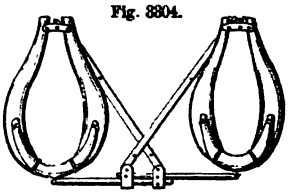
Neck Yoke and Straps.

Neck-yoke. A bar, usually of wood, by which the end of the tongue of a wagon or carriage is supported. The *breast-straps* or *chains* pass through the rings on the hames, or, in the case of carriages, the straps pass around the lower part of the collar.

Animals in ancient Egypt were universally attached to their work by yokes. This was the case with horses, asses, or oxen, to wagons, chariots, or farming implements.

In a modified form, hinged plates are clasped around the neck-yoke, and the central clasp has plates perforated to receive the end of the tongue. Leather is inclosed between the two plates. The end straps are secured to the neck-yoke by metallic straps.

Fig. 3304.



Draft Neck-Yoke.

The cut shows the several parts.

Fig. 3304 shows a draft neck-yoke in which the collars are braced together and to a rod which is secured to the tongue, so that the draft is by the latter, dispensing with traces.

Nee'dle. 1. A pointed instrument for carrying a thread through a fabric, leather, or paper. It usually passes through the fabric and drags the thread after it, but it is otherwise with eye-pointed needles, such as packing-needles, and those in sewing-machines. The last-mentioned are really awls.

Needles of bone are found in the caves occupied by the ancient inhabitants of France during the stone period, and the same material is in use among uncivilized tribes at the present day.

The needles of ancient Egypt, as described by Wilkinson, are of bronze, and no eye is apparent in his illustration of them. It would rather seem that the thread is attached to a circular depression near the blunt end. It would be hardly reasonable to doubt that they had needles with eyes. We know from Scripture and secular history and from the tapestry that has survived thirty centuries that they were skillful and painstaking seamstresses.

> "A woman must not go out on the sabbath
> With a needle that has an eye."
>
> MISHNA.

The Phrygians and Hebrews held fine needlework in high estimation. Needles of bronze were used by the Greeks and Romans, are described by Pliny, and have been found in Herculaneum.

The history of art progress during the Middle Ages is a blank, but we find that needles were manufactured at Nuremberg in 1370. The history of their manufacture in England is involved in doubt, but it is said to have been introduced about 1543–45, either by a Spanish negro or a native of India, who died without disclosing the secret of his process. It was recovered during the reign of Elizabeth, by Growse, a German.

In 1650, Christopher Greening and a Mr. Damer established needle-factories at Long Crendon, near Redditch, and were soon followed by other needle-makers from London.

Redditch is yet the great center of the English needle manufacture.

The earliest needles were "square-eyed," that shape being most readily produced. "Drill-eyed" needles, after many unsuccessful attempts, were first brought out in 1826. The burnishing machine, in which the needles are strung on a steel wire to which rapid revolution is imparted, was introduced two

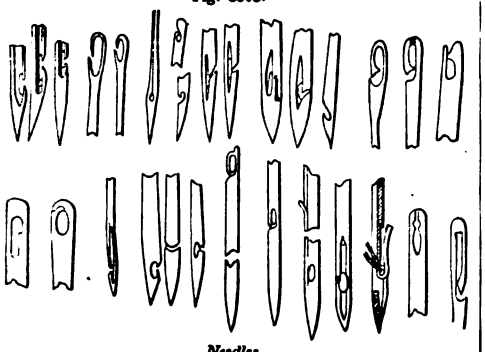
Digitized by Google

years later. By this, a beautiful finish is imparted to the eye. The process of hardening them in oil was introduced in 1840, water having been previously used for this purpose, which caused a large proportion of them to become crooked, requiring the services of a large number of workmen to straighten them. These being thrown out of employment by the new process made a riot and drove its introducer out of town, but it was finally generally adopted. A similar disturbance had taken place in 1830, on the introduction of the stamping-machine. The machine for pointing is of still more recent introduction.

A needle with a point at each end and an eye at the middle of its length was patented in England in the year 1755, for hand-sewing or embroidering, the patentee describing it as used by holding it with the fingers at the middle of its length, so that it will not require turning. In 1829 it was successfully introduced into an embroidering-machine, which is still in extensive use. As many as one hundred and thirty such needles, worked by pincers on opposite sides of the fabric to be embroidered, are used in a single machine. In 1842 a sewing-machine inventor adopted the same kind of needle, and some others have made sewing-machines with such needles, but no such machines have ever been successful.

The accompanying cut shows a number of patented needles, some with eyes near their points, some

Fig. 3305.



Needles.

having means of slipping the thread into the eye without reeving.

Needles are known as *sharps*, *betweens*, *blunts*, according to the relative fineness of their points.

The so-called *golden-eyed* needles are tinted by dipping in an ethereal solution of gold.

The *silver-eyed* needles are not really silvered, but the silvery hue is given by a peculiar polish.

The *blue-pointing* is a dark polish effected by applying the needles to a revolving stone of a bluish color.

The *drilled-eyed* needles have the eyes finished by a countersink drill, the eye end being previously softened.

Bell's *needles*, English patent, are made of steel, *cast* in sand molds.

The mode is particularly intended for bodkins, fish-hooks, knitting, netting, packing, and sail needles.

2. (*Surgical.*) The *acupuncture*-needle is a gold or silver needle, four inches long, with a handle. See ACUPUNCTURATOR.

The *cataract*-needle is a steel, inflexible needle, 15 to 24 lines long, and is employed to depress or tear the opaque crystalline lens. The extremity may be as in Scarpa's and Langenbeck's, pointed, prismatic, triangular, and curved. In Duputren's and Walther's, flat, curved, and sharp-edged. In Hey's, flat, with a sharp end. In Beer's, Siebold's, Schmidt's, Himly's, Von Gräfe's, straight and spear-pointed. A mark is placed on the handle to indicate the side corresponding to the crystalline when the instrument is in the eye.

The *counter-opening* needle, or *acus invaginata*, is a long, narrow steel needle with a point sharpened on both sides. The heel has an aperture to receive a thread or tape. It has a sheath to cover the point in passing critical places.

The *fistula*-needle is a flat, flexible silver instrument, with a point at one end and an eye at the other to lead in a seton. Its side is grooved to form a leader for a bistouri. Also a steel instrument like a trocar.

The *hare-lip* needle is a small silver canula with a spear-point.

The *ligature*-needle has a point and eye, and was formerly used to pass a ligature around the artery and a portion of the integuments to suspend circulation prior to amputation. Or a steel curved needle with a lance-point and long eye to pass a ligature around a vessel. See LIGATURE-CARRIER.

The *seton*-needle, a long, narrow steel blade with a point and eye.

A *suture*-needle. For a twisted suture the hare-lip needle; a straight needle for stitching up after dissection; or a curved needle, flat on one side and with a sharp ridge on the other.

See also ACUS.

3. (*Nautical.*) *a.* The seaman's and sailmaker's needles are *seaming*, *bolt-rope*, and *roping* needles; they are three-sided.

b. The polarized steel of a mariner's compass.

4. (*Sewing-machine.*) The eye-pointed instrument for carrying thread through the cloth.

5. (*Weaving.*) A horizontal piece of wire with an eye to receive the lifting-wire in a Jacquard loom. See JACQUARD; PATTERN-CARD.

6. (*Hydraulic.*) One of a set of vertical square bars of wood in a timber frame in a weir. These *needles* stand close together, and close the opening which forms a sluice-way. They are capable of being removed separately to open a way for the water.

7. (*Hoisting.*) A beam projecting from a building, with a pulley at its outer end, the *fall* worked by a crab placed inside the building.

8. A tool for pricking the cartridge to make connection between the charge and the priming. See BLASTING-TOOLS.

Nee'dle-bar. 1. (*Knitting.*) In a stocking-frame, a bar in which the needles are fitted with their leads.

2. (*Sewing-machine.*) The reciprocating bar to whose end the needle is attached.

Nee'dle-beam. (*Civil Engineering.*) A trans-

Digitized by Google

verse floor-beam of a bridge, resting on the chord or girders, according to the construction of the bridge.

Nee'dle-bear'er. (*Surgical.*) A *porte-aiguille* forming a handle for a needle.

Nee'dle-car'ri-er. (*Surgical.*) A *porte-aiguille.*

Nee'dle-case. A book or wrapper in which needles are kept in the pocket or the work-table.

Nee'dle-file. A long, round, narrow file used by jewelers.

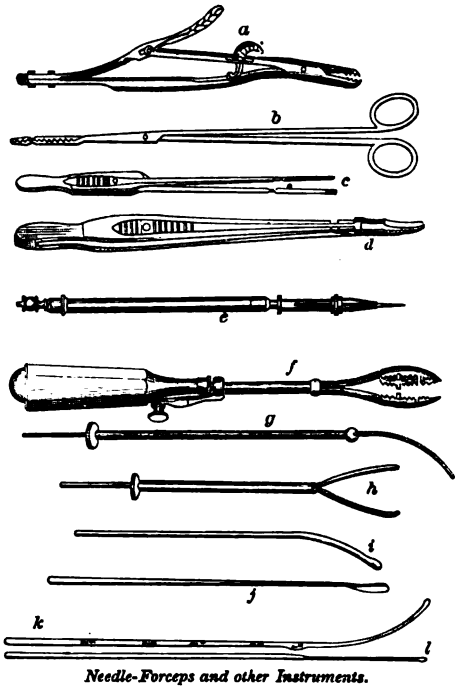
Nee'dle-for'ceps. An instrument to hold a needle to sew up wounds that cannot be reached by the hand, such as in vesico-vaginal fistula or uterine operations, or to hold very minute needles in operations about the eye or in staphyloraphy.

Sands's and Sims's, late American inventions, rank among the best.

a is a locking forceps.

b c d are forms used for general purposes of driving and holding needles, catching and twisting silver wires, applying and moving sponge-tents, etc.

Fig. 3306.



Needle-Forceps and other Instruments.

e is a draftsman's needle-holder.

f is a modification of Roux's needle-holder, which may be used in the operations of vesico-vaginal fistula, cleft palate, etc., and is made to serve as a handle to the instruments accompanying it, and which are manufactured one half their full length. When the handle is applied to either one it gives it its full length.

g combines the *applicator* with the sponge-tent expeller.

h is a sponge-holder and ligating forceps.

i, a lead sound, which easily follows the curve of the uterus.

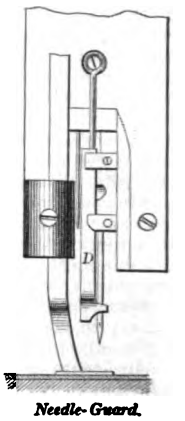
j, intra-uterine scarifying knife, blunt point.

k, Simpson's sound.

l, uterine probe of silver.

Nee'dle-guard. (*Sewing-machine.*) A sliding piece which moves with the needle and keeps it in line during rapid movement, so that it shall not strike wide of the hole in the cloth-plate.

Fig. 3307.



Needle-Guard.

That in the example is a supporting brace or bar *D*, which slides vertically. In this instance, as the feed is effected by the needle, the bar has a lateral movement coincident with that of the needle.

Nee'dle-gun. (German, *Zündnadelgewehr.*) A fire-arm which is loaded at the breech with a cartridge carrying its own fulminate, and which is ignited by a *needle* or pin traversing the breech-block and struck by the hammer.

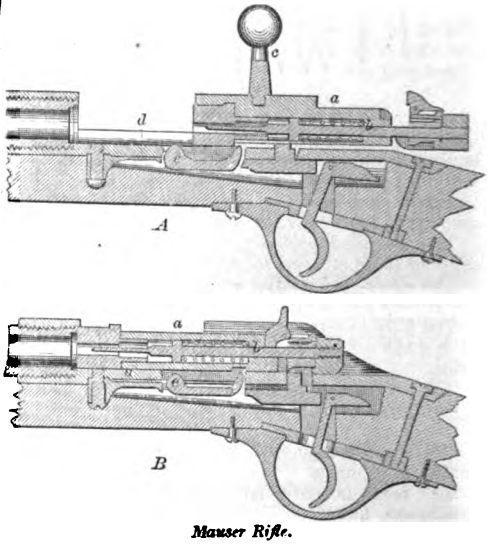
There are many guns of this construction, such as the converted Enfield (see CONVERTING); but the one which has attained so great celebrity, though by no means the best of its class, is the Prussian needle-gun, which performed so effective a part in the Prusso-Austrian war of 1866. See FIRE-ARM, cut *C*, Plate XVI. The French chassepot-gun is shown at *B*, same plate.

The Prussian piece was invented by Mr. Dreyse, who is said to have spent over thirty years in trying to construct a perfect breech-loading fire-arm.

It was introduced to some extent into the Prussian service about 1846, but was much improved afterward. It has since been superseded in the North German army by the Mauser rifle (Fig. 3308). *A* shows the breech mechanism in position for loading, and *B* at half-cock.

The breech-piece *a* is perforated to receive the needle *b*, and is operated by the lever *c*, by which it is turned quarter round and drawn backward,

Fig. 3308.



Mauser Rifle.

retracting the needle until a catch thereon drops into a notch by which it is retained until released by the action of the trigger, when it is driven forward by a spiral spring.

An extractor works in a groove at the side of the shoe *d*, withdrawing the cartridge-case when the

Digitized by Google

breech-piece is drawn backward. This movement brings the case in violent contact with the ejector *e*, by which it is thrown out.

A Berlin correspondent of the London "Times" gives an account of the performance of this new arm: "On a distance of 1,500 metres (1,640 yards), out of 480 shots, 399 hits were effected in five targets placed behind each other; and on 1,400 metres (1,564 yards), out of 480 shots, 460 hits are reported."

Nee'dle-hold'er. 1. A draftsman's instrument for holding a pricking-through needle. (*e*, Fig. 3306.)

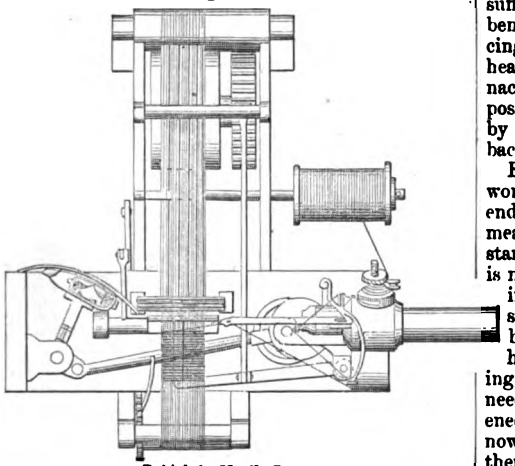
2. A surgeon's appliance for holding needles during operations. See NEEDLE-FORCEPS.

Nee'dle-in'stru-ment. (*Surveying.*) One which owes its accuracy and value to the magnetic needle only, such as the *plain* or the *Vernier compass* or the *Vernier transit.*

Nee'dle-loom. One in which the weft is carried by a needle instead of a shuttle. The usual form of loom for narrow wares, such as ribbons, tapes, bindings, etc. In the example, the filling is carried through the shed by a reciprocating eye-pointed needle, and the loop of the weft looked at the selvage by the passage through it of a shuttle and its thread. The weft-retractor swings freely on a pin; its shorter arm, when thrown fully back by a projection, rests in a notch on the needle-guide, until the pull of the needle passing through the shed detaches it and draws the retractor forward, taking up yarn from the bobbin.

The shuttle operates in an arc of a circle parallel to the plane of the warp, so that in approaching to enter the loop of the weft-yarn it moves nearly parallel with and close to the selvage of the web being woven, and afterward gradually moves away

Fig. 3309.

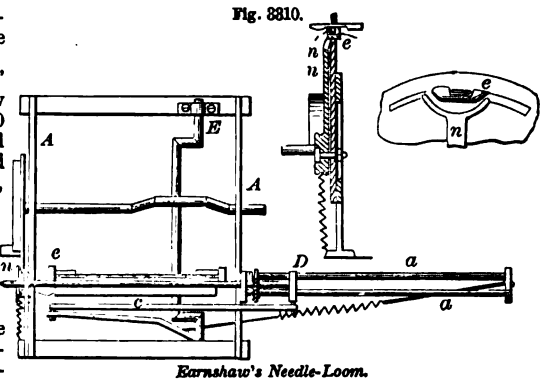


Robjohn's Needle-Loom.

from the warp, so that in completing its movement at the same time as the needle completes its retiring movement it pulls its yarn or thread tight in a direction transverse to the warp.

In Fig. 3310, the needle is eye-pointed and the weft-thread is carried by it in lieu of a shuttle. A shuttle-thread engages the loop, and the rod is retracted, leaving two filling-threads in the shed. The needle-stock *D* slides on bars *a a* projecting from the side of the loom, and is actuated by a rocker-shaft *E*, a vibrating arm *c*, and connections. The ordinary cap-piece of the reed is removed to permit

Fig. 3310.



Earnshaw's Needle-Loom.

free manipulation of the warp. The shuttle *e* has a segmental guide groove, and is operated by a divaricated arm upon a rocker-shaft *n*, its two horns engaging the back end of the shuttle alternately.

In Jackson and Merrill's needle-loom, the weft-thread is carried by a needle through the shed and is interlocked by a shuttle-thread, returning to its normal position before the shed changes. The needle is passed through the under part of the shed near the reeds, so as to preserve it from contact with the warps. The needle then receives a swinging movement that passes its end around a standing shuttle or bobbin, the needle returning through the shed near the point of weaving, so that the lay has to move the weft-thread but a short distance.

See also RIBBON-LOOM; NARROW-WARE LOOM.

Nee'dle-mak'ing. Needles are made from soft steel wire, which is received from the manufactory in coils. The wire is cut by fixed shears into lengths sufficient to make two needles; these blanks, being bent, require straightening, which is done by placing several thousands of them between two broad heavy rings and heating them to redness in a furnace. They are then removed, and placed, still in position within the rings, on a flat iron plate, and by means of a curved bar, termed a *smooth file*, rolled back and forth until perfectly straight.

Each piece is then sharpened at both ends. The workman takes up a number at a time and holds the ends against a grindstone, forming the points. By means of a die and counter-die, two grooves are stamped by a press on each side of the wire, which is next pierced under a press with two holes, forming the eyes. A number of pieces are then strung on two fine wires and broken each in two by filing and bending. The roughness about the head is removed by filings, several at a time being placed in a small vise. During these processes the needles, having become somewhat bent, are straightened by rolling on a flat plate, as before. They are now brought to a red heat, and tempered by plunging them into oil. 50,000 at a time are then put in a canvas bag with emery, oil, putty-powder, and soft-soap, and rolled to and fro under pressure until they become bright.

The better class of needles have their eyes drilled. The final process is polishing the points, which is effected first by a rotating hone and afterward by a buff-wheel.

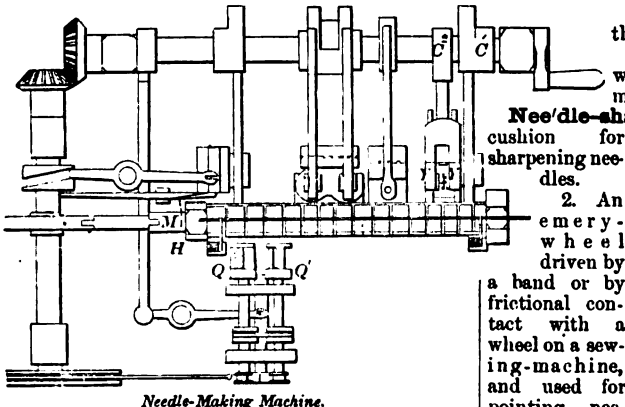
Nee'dle-mak'ing Ma-chine'. Of late years machines have been introduced by which needles are formed from the roll of wire without the intervention of hand labor.

Fig. 3311 illustrates Barton's machine. In this, the wire is fed forward to a rack *M*, and cut to

Digitized by Google

length by the cutter *H*, being received in a groove of the bed-piece below the rack. The rack has a reciprocating movement both longitudinally and vertically; the latter serving to pick up the blank from each groove in the bed-plate, and the former to advance it to the next groove. At each groove it is

Fig. 3311.



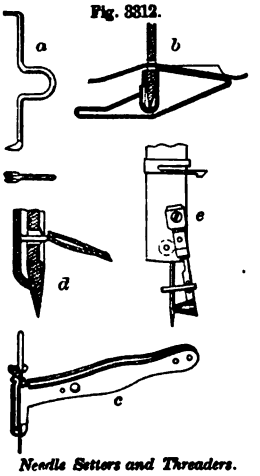
Needle-Making Machine.

subjected to the action of a die or punch, which dies successively form the groove for the eye and punch the eye. These are operated by the cams C^1 C^2, etc. It is then in the same way advanced, so as to be milled by the milling-tool *Y*, after which it is brought back, and while partially held by the reciprocating rack its point is finished by the revolving sharpeners *Q Q'*.

Nee'dle-pa'per-ing Ma-chine'. (*Metal-working.*) The needles are placed point foremost in a hopper whose bottom is divided by partitions forming spaces corresponding in width to the length of the needles. The hopper has a traversing motion by which the needles are arranged in rows, and on arriving at the proper point a pusher is caused to strike the end of each row, sticking the needles in the paper, which is advanced and crimped as they are presented to it.

Nee'dle-point'ing Ma-chine'. This comprises a grooved grindstone, to which the wires, cut to the desired length, are applied by an inclined plane. A disk covered with rubber revolves transversely to the grindstone, turning the needles round so as to present each point of their circumference to the stone, at the same time continuously furnishing a fresh supply for its action.

Fig. 3312.



Needle Setters and Threaders.

Nee'dle-set'ter. An attachment to a sewing-machine to allow the needle to be set in its bar, so that the eye of the needle shall be at the proper distance from the end of the bar, in order that the loop may be properly formed and at the right place for the hook or shuttle beneath the fabric. Fig. 3312 shows several forms.

a is a trial bar, whose upper end rests against the needle-bar and its lower point in the eye of the needle.

b is a shield which fits against the eye of the needle and has a channel to lead the thread.

c is a clasp to hold the needle, a point determining the position of the latter in the clasp which is placed against the needle-bar in adjusting the needle.

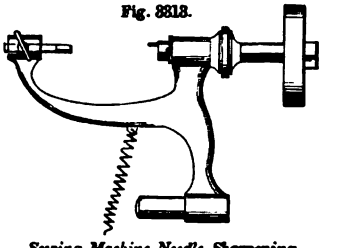
d has a bar with a hook to draw the thread through the needle-eye.

e has a latch which is brought down when required to indicate the adjustment of the needle in the stock.

Nee'dle-sharp'en-er. 1. An emery cake or cushion for sharpening needles.

2. An emery-wheel driven by a band or by frictional contact with a wheel on a sewing-machine, and used for pointing needles.

Fig. 3313.



Sewing-Machine Needle-Sharpening Attachment.

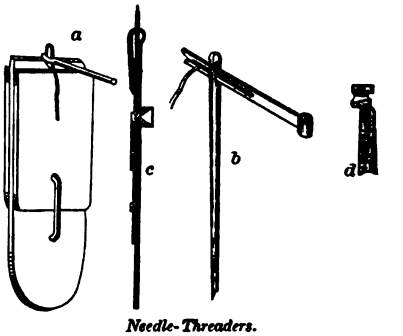
Nee'dle-tel'e-graph. A telegraph in which the indications are given by the deflections of a magnetic needle whose normal position is parallel to a wire through which a current of electricity is passed at will by the operator.

In practice, the needle is rendered astatic (see ASTATIC NEEDLE), and inclosed by a coil by which the effect of the electric current is multiplied. This is the principle of the *galvanometer* and of the electric telegraph of Cooke and Wheatstone, which is used in England. See INDICATOR-TELEGRAPH.

Nee'dle-thread'er. A device to assist in passing a thread through the eye of a needle. There are two kinds, and many varieties of a kind.

a is a form in which the thread is caught in a

Fig. 3314.



Needle-Threaders.

crotch and pushed through the eye of the needle.

In *b* it is caught by barbs and drawn through the eye.

In *c* and *d* the needle is adjusted opposite to a cone which directs the thread.

Nee'dle-wrap'per. A case or housewife to hold needles for the pocket or work-table.

Neg'a-tive. 1. (*Photography.*) A picture upon glass, in which the lights and shades are exactly reversed; the actual shades being represented by the transparent glass, the lights of the object show-

Digitized by Google

ing dark by the opaque material (reduced silver) on the glass.

The *negative* is used to obtain *positives*, being laid upon the sensitized paper which is acted upon by the sun's rays passing through the glass. The rays being but little impeded by the transparent portions make the darks of the *positive*, and being intercepted by the opaque silver make the lights and light shades of the positive picture.

Negatives are usually taken on glass coated with a film of collodion, which is sensitized for the purposes of the camera. The principal use of negatives is for obtaining positive prints.

2. (*Electricity.*) The metal or equivalent placed in opposition to the *positive* in the voltaic battery.

The *negative* may be coke, carbon, silver, platinum, or copper, and forms the *cathode*.

The *positive* is usually zinc, and its pole is the *anode*.

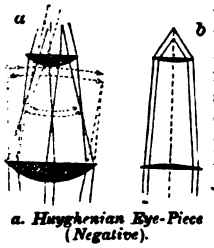
In the following order of metals the most negative is at the head of the list: —

Platinum.	Copper.
Gold.	Lead.
Antimony.	Iron.
Silver.	Tin.
Nickel.	Cadmium.
Bismuth.	Zinc.

Neg'a-tive-bath. (*Photography.*) The *bath-holder*, also known as the "bath," is a vessel used to contain the nitrate of silver solution, or bath used by photographers for making negatives. It is made most commonly of glass, but also of hard rubber and porcelain, and sometimes wood covered with asphaltum and other substances. Formerly, horizontal baths were used for large plates; these were tilted so as to throw the fluid to one end, the plate was then introduced with the collodion side upward, and the fluid allowed to return in an even wave over its surface by restoring the bath-holder to the horizontal position. Upright bath-holders are now almost always used. The best are made of glass, blown and pressed for negative plates of moderate dimensions, and constructed of pieces of thick plate-glass cemented together for larger sizes, protected externally with a strong covering of wood. The length and depth of such a vessel must suit the negative plate which is to be immersed in the upright column of solution; its width may vary from three quarters of an inch to two or even three inches. The latter, though less economical of solution in the first instance, are more so in the long run.

Neg'a-tive Eye-piece. The *Huyghenian*, or *negative eye-piece*, *a*, is the usual combination of lenses at the eye-end of a telescope or microscope. It was designed by its inventor to diminish the spherical aberration by producing the refractions at two glasses instead of one, and also to increase the field of view. It consists of two plano-convex lenses, the eye-glass and the *field*-glass, each of which presents its convex side towards the object-glass.

Fig. 3815.



a. Huyghenian Eye-Piece (Negative).

The glasses are separated from each other by about half the sum of their focal distances, the image viewed by the eye being formed between the two lenses.

b shows the *positive* eye-piece, in which the convex sides of the lenses are turned toward each other. See POSITIVE EYE-PIECE.

Neg'a-tive-well. A name for an absorbing or draining shaft, bored or dug in the ground and used to carry water through a retentive to a porous stratum in which it may escape. See ABSORBING-WELL; DRAIN-WELL.

Nei-gel'li-cloth. An Indian fabric made of *pat* or *sunn* hemp. *Crotalaria juncea.*

Ne-o-mon'o-scope. An instrument for magnifying photographs. Invented 1862.

Ne-paul'-pa'per. A strong, unsized paper made in Nepaul from the pulverized bark of the *Daphne papyraceæ*. Made many yards square.

Ne'phel-o-dom'e-ter. An instrument for ascertaining the distances of the clouds.

Ne'phel-o-rom'e-ter. An instrument for ascertaining the speed and direction of motion of the clouds.

Ne-phel'o-scope. An instrument contrived by Professor Espy to illustrate the law of the formation of aqueous vapor into clouds.

Nerve In'stru-ments. Dentists' instruments for obliterating or extracting the nerve in the root of a tooth.

Instruments for excavating and filling nerve-cavities are *burs*, *drills*, *excavators*, and *pluggers*.

Fang-fillers, *canal-pluggers*, *pulp-canal reamers*, *probes*, are also used about the nerve-canal, their purposes being indicated by their names. See BUR-DRILL.

Nerve-nee'dle. 1. (*Dental.*) A tool used for broaching out the nerve-canal to enable it to hold a dowel-pin which secures an artificial crown to the root of a natural tooth. See BROACH.

2. (*Surgical.*) An *esthesiometer* is an instrument with a pair of needles, to ascertain the tactile sensibility of different parts of the body. It has two points, adjustable as to distance, and the object is to ascertain the nearest proximity at which the points give distinct sensations. The distances vary much at different parts of the body. See ESTHESIOMETER. See also NEUROTOME.

Nest. 1. (*Gearing, etc.*) A connected series of cog-wheels or pulleys.

A set of articles of diminishing sizes, each enveloping the one next smaller in size; as a nest of crucibles, tubs, or the like.

2. *a.* A place for hens to lay. The ingenuity is scarcely appreciated by the hens, who have a modest preference for hiding upon such occasions.

The same may be said of the elaborate preparations for canaries during confinement.

b. A box for martins or sparrows on a post or in a tree.

Net. 1. A device for catching fish, birds, or other animals. It is made from a texture woven or knotted with large interstices or meshes.

Johnson defines network to be "anything reticulated or decussated with interstices between the intersections." The fabric is also used for securing or containing articles of various kinds. The *dip-net* is made in the form of a bag, the mouth of which is distended by a hoop, and is provided with a handle.

When long and narrow, having floats on one side and sinkers on the other, so as to prevent the escape of fish in shoal water, it is called a *seine*.

Nets were used by the ancients for fowling, hunting, and fishing. They were usually made of flax or hemp, and were large or small according to the purpose intended.

Nets extended on stakes and forming a corral are mentioned by the Roman writers.

A purse or tunnel net was used at the end of wing-nets.

Six kinds of fishing-nets are mentioned by Oppian.

Digitized by Google

Three of these were casting, landing, and drag nets.

The *seine* (*Sagena*) is a Greek net in name and in form.

Corks or wooden blocks, to float the upper edge of a net, and weights to depress its lower edge, are seen in Egyptian paintings; exist on an old Egyptian net now in the Berlin Museum; and are mentioned by Pliny, Ovid, and other writers.

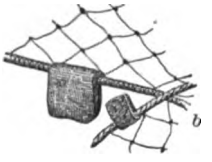
The Grecian fishing-nets also had corks and leaden weights.

Fishing was a great business in Egypt, and a painting in a tomb near the Pyramids represents a large drag-net, with floats and sinkers, in the act of being hauled by seven men, who stand on a decked boat and act under the direction of an overseer. *b* is a portion of a net with sinkers, from the Berlin Museum.

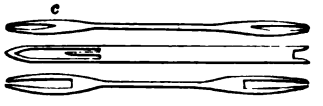
a, Fig. 3316, is an illustration from a painting in

Fig. 3316.

a



b



c

Egyptian Nets and Netting.

a tomb at Thebes, showing the mode of trapping the wild goose, which is still common on the banks of the Nile. It is similar to the common clap-net, and the rope was pulled by men secreted behind the reeds. The view shows the birds settling in the net, and a man standing behind the reeds enjoining silence. Another man stands directing the men. The reed represented is intended for the papyrus.

The ancient Egyptians made bird-nets of split reeds. Such were used in catching quails by the unfortunate outcasts on the edge of the desert forming the boundary between Egypt and Syria. This community, if it can be so called, was made up of robbers who were banished by Actisanes the Ethiopian, who was then on the throne of Egypt. Actisanes had a scruple on the subject of the death penalty, and adopted the practice of cutting off the noses of robbers and banishing them to a land where they had very hard work to obtain a living, and could disturb nobody.

c shows an ancient Egyptian netting-needle, found in Thebes, and now in Mr. Salt's collection. Their netting-needles were of wood, very like our own, split at each end, and between 10 and 11 inches in length. Others were of bronze, and the slightly elastic prongs would close except when the twine passed. Their nets were of flax twine. Pieces have come down to our day, and are preserved in the European museums.

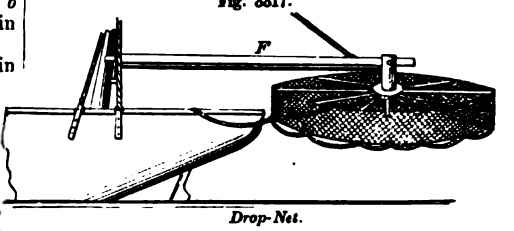
A netting-needle of wood, charged with the original thread, was found among other articles in a lady's work-basket.

In *netting*, the threads or cords are tied into hard knots at their intersections, so as to form meshes, which always continue of the same size.

The French government, in 1802, offered a reward of $10,000 to the person who would invent a machine for making knotted nets. It was adjudged to M. Buron, but the machine has not come into general use.

Fig. 3317 illustrates a device for casting a circular

Fig. 3317.

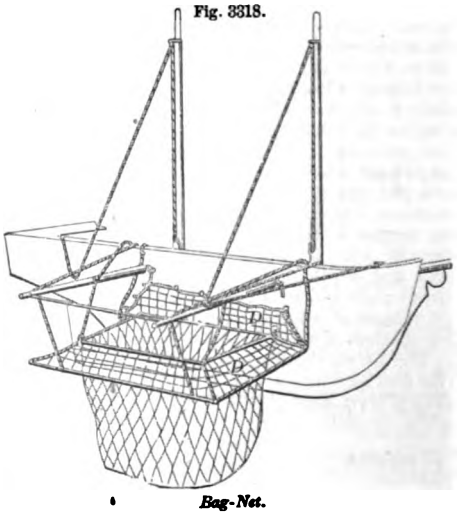


Drop-Net.

net. The net is extended upon a bolt beneath a boom *F*, and is cast by withdrawing the bolt.

In Fig. 3318, the net is suspended by booms from the vessel's side, and has a flanged edge *D*, which is

Fig. 3318.



Bag-Net.

raised when the net is "drawn," to prevent the escape of fish.

2. A kind of lace made by machinery.

In the last century various kinds of these fabrics were made; called *whip-net*, *mail-net*, *patent-net*, *drop-net*, *spider-net*, *ballom-net*. The present varieties, deriving their name from the kind of mesh, are POINT-NET, WARP-NET, and BOBBINET (which see).

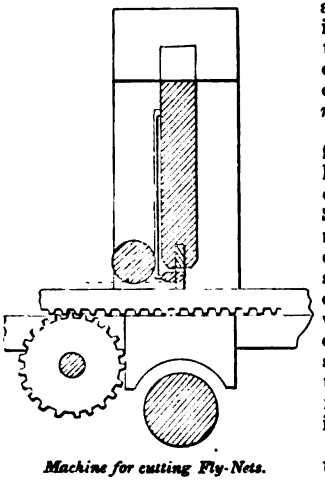
Several varieties of machine-made *net* are named from some peculiarity of fabrication.

Broad-net is woven the whole width of the machine.

Quillings are narrow strips, of which many may be made simultaneously in the breadth of the machine.

Digitized by Google

Fig. 3319.



Machine for cutting Fly-Nets.

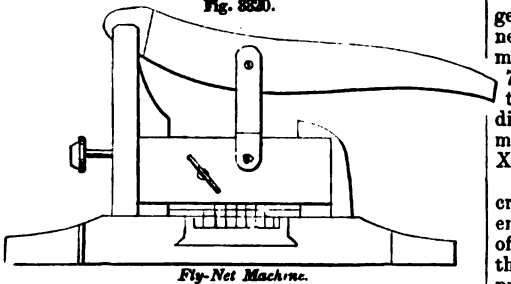
Fancy-net has a pattern worked in with gimp by the Jacquard; or by hand, called *lace-running*.

3. A covering for horses in harness, to deter or dislodge flies. Such nets are made by a succession of short slits in quincunx order, so that when the piece of leather is stretched out, the slits expand into wide openings.

In Fig. 3319, the leather is fed upon an intermittingly moving cutting-board underneath a pair of knives arranged in a guillotine sash; a spring-block steadies the leather and prevents its being drawn up when the knives rise.

In Fig. 3320 the cutters are confined in a lozenge-shaped cavity by wedge-blocks and a set-screw. The cutters have metallic blocks between them by which

Fig. 3320.



Fly-Net Machine.

the breadth of the laces is governed. The knives are depressed upon the leather by a lever, and the leather is then drawn through beneath them.

Other nets are of cord, made in the manner of fishing-nets by shuttle and mesh-stick.

A substitute for nets for horses consists of leather strings, with a few bands to keep them in place at their proper distance apart.

Net-ma'son-ry. Reticulated bond, the joints of which resemble in appearance the meshes of a net.

Net'ting. Open-work fabric for curtains or screens. See MUSQUITO-CANOPY, etc.

Net'ting-ma-chine'. Lace is said to have been first made by machinery in 1768 by Hammond, a stocking-weaver of Nottingham, England, who invented what was known as the *pin-machine*, for making single-press point-lace in imitation of Brussels ground.

The *warp-frame* for making warp-lace was introduced in 1782. The first attempt to make bobbinet by machinery was in 1799, but no successful machine was produced prior to 1809, when Heathcote patented his machine, in which, by means of bobbins, a series of diagonal weft-threads are passed around and intertwisted with the parallel threads of the warp. Many subsequent improvements were made on this machine, which has been variously modified to produce different kinds of netted fabrics, among which we may enumerate —

The bobbinet-machine.	Traverse-warp machine.
Lever-machine.	Twist-machine
Straight-bolt machine.	Pusher-machine.
Circular-bolt machine.	

The *warp-machine*, based on the stocking-frame, was invented about 1795, and is employed in making lace, and also knit jackets, "Berlin" gloves, and similar articles. See BOBBINET-MACHINE; LACE-MAKING MACHINES.

Net'ting-nee'dle. A shuttle used in netting. One from the tombs of ancient Egypt is of the same form as used at the present day. (*c*, Fig. 3316.) See also TATTING-SHUTTLE.

Net'tings. (*Nautical.*) Nets of small rope used on board ship for various purposes, such as holding the hammocks when on deck, or for stowing sails. Also for hanging between the bulwarks and the rigging to repel boarders.

Net'tle-cloth. (*Fabric.*) A thick cotton stuff, japanned, and used as a substitute for leather.

Net'tling. (*Rope-making.*) *a.* A process whereby two ropes are joined end to end, so as to appear as one. The ends are scutched or beaten out, and spun or twisted together.

b. The tying of the yarns in pairs to prevent their becoming entangled or confused when laid upon the posts in the ropewalk.

Neu-rot'o-me. (*Surgical.*) A long, narrow scalpel, used by anatomists to dissect the nerves. *Neurectome.*

Erasistratus of the Alexandrian College of Surgeons, in the Ptolemaian period, wrote upon the nerves, and knew the distinction between those of motion and those of sensation. — *Ency. Brit.*, II. 751. Rufus of Ephesus, who was probably contemporary with Trajan, in his works on anatomy, divided the nerves into those of sensation and of motion. — *Nouvelle Biographie Générale*, Tome XLII. p. 882.

Nevertheless, Sir Charles Bell and Mr. Mayo are credited by Whewell (History of the Inductive Sciences, III. 425) with the discovery "that the two offices of conducting the motive impressions from the central seat of the will to the muscles, and of propagating sensations from the surface of the body and the external organs of sense to the sentient mind, reside in two distinct portions of the nervous substance."

New'el. 1. (*Carpentry.*) The post at the head or foot of a stairs, supporting the hand-rail.

The center-post of a winding stairs is a *solid newel*. Winding stairs around a central well are said to have an *open newel* or *hollow newel*.

2. (*Shipwrighting.*) An upright piece of timber to receive the tenons of the rails that lead from the breastwork of the gangway.

New-sand. (*Founding.*) Facing-sand.

News'pa-per. The newspaper, like many other useful inventions, seems to have originated in China. The Pekin "Gazette," the oldest daily in the world, was first issued about A. D. 1350. This is still in existence, and is an official journal, containing such information as the government chooses to make known. It is composed of three parts: 1. The court journal, or "copy of the door of the palace," which announces day by day the list of functionaries on duty, the actions of the emperor, the presentations, visits, departures, etc.; 2. The imperial decrees; 3. The reports of the great officers of the crown. It forms a pamphlet of 20 to 40 pages of coarse paper, printed from wooden types on one side only, and having a paper cover. It has a cir-

Digitized by Google

culation of many thousand copies, which are distributed to subscribers in the city or sent in packages to the provinces. The subscription price is about $6 per year, but many copies are hired for the day and returned in the evening.

In the last century the Jesuits introduced copper types, rendering the paper much neater in appearance, as well as saving labor; but in 1820 the wooden type previously used was again brought into requisition.

Its contents are often of a curious nature. Recently a petition appeared, praying the emperor to confer a title of honor upon a female spirit who had performed various services, such as filling with water the channel of a river in a dry season, and destroying or dispersing bands of rebels. The rage for obtaining office, and the practice of stealing after obtaining it, indicate that China is not, in some respects, behind countries claiming a higher degree of civilization. The oldest applicant recently gazetted, aged 102 years, passed his civil-service examination with eclat, and numerous others are over 90, none of the juniors owning up to less than 70 years.

A general is denounced for conducting but 3,000 men against the rebels instead of 5,000, the number for which he drew pay, pocketing the difference.

The origin of newspapers in Europe may be traced to the "Notizie Scritte" of Venice, written sheets, containing news items, etc., which still maintained their circulation at a comparatively recent period, owing to the restrictions placed on the press in Italy.

To Germany and England are due the first printed periodical publications.

The first English newspaper authentically known was entitled "News out of Holland"; it was established in 1619, and published at irregular intervals. This was succeeded by "Certaine News of the present Week," the first number of which was issued May 23, 1622, and was followed within the next five years by a number of other regularly published journals.

During the period of the Commonwealth and the Restoration their number multiplied, but none appear to have been published oftener than once a week until about the reign of Queen Anne, when the demand for news from the Duke of Marlborough's army led to their being issued tri-weekly.

The first London daily was the "Courant," published by Samuel Buckley in 1703. The first established newspaper in England, outside of London, is believed to have been the "Norwich Postman," 1706.

The first actually published in Scotland was at Edinburgh in 1654.

The "Dublin News-letter," the earliest Irish paper, was established in 1685.

In the United States a newspaper was attempted as early as 1690. The first number was dated September 25 of that year, but its farther issue was prevented by the colonial government, it being "published contrary to law, and containing reflections of a very high nature." In 1704 the "Boston News-letter," published "by authority," was established by John Campbell, and in 1719 the "Boston Gazette," also "by authority." To these succeeded the "New England Courant," by James Franklin, a brother of the Doctor. Andrew Bradford founded a paper at Philadelphia in 1719, and his father, William Bradford, issued the first newspaper published in New York, the "New York Gazette," in 1725. From this period they multiplied rapidly in the Colonies.

The common name "Gazette" is derived from the name of a Venetian coin, worth about a cent and a half, and which was the price of the Venetian newspaper first published.

The "Maryland Gazette" was established in 1727 or 1728; the "Virginia Gazette," 1736; the "Rhode Island Gazette," 1732; "South Carolina Gazette," 1731 or 1732; "Georgia Gazette," 1763.

The first paper in New Hampshire was published in 1756, but in the adjacent State of Vermont none existed prior to 1781.

After the Revolution, the history of newspaper progress becomes identical with that of the nation, the printing-press keeping closely in the van of Anglo-American civilization.

The honor of publishing the first paper west of the Alleghanies is claimed for John Scull of Pittsburgh, who, it is stated, founded the "Pittsburgh Gazette" in 1783.

The first north of the Ohio River, being the third or fourth west of the Alleghanies, is said to have been the "Centinel of the Northwest Territory," by William Maxwell, 1793.

According to De Saint Foix, the earliest French newspaper, called the "Gazette de France," was established by Renaudot, a physician, who obtained a royal grant of the exclusive privilege of publishing the same for himself and family. He had previously been in the habit of collecting information and circulating news-sheets among his patients.

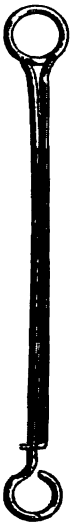
The first German newspaper was established at Frankfort in 1615. An illustrated war gazette, the "Niewtijdinge," published in the Low Countries, had, however, preceded this by ten years.

In Sweden, a newspaper was published as early as 1643, entitled the "Ordinarie Post Tidende."

Journalism in Spain and Italy, owing to the lack of general education, and restrictions on the liberty of the press, has, until recently at least, remained in rather a backward state. In the former country newspapers issued at irregular intervals were published during the seventeenth century, but those appearing regularly do not seem to have been introduced until the next; and in Italy, though never entirely suppressed, their continuance under the depressing influences by which they were surrounded, produced no one of extensive circulation or influence.

The same may be said of Russia, where the periodical press was first introduced under the auspices of Peter the Great; and of Turkey, whose first newspaper only dates back to 1795.

Fig. 3321.



Newspaper-File.

News'pa-per Ad-dress'ing-ma-chine'. A machine for printing addresses on newspaper wrappers or attaching printed labels to newspapers or their wrappers. See ADDRESSING-MACHINE.

News'pa-per-clamp. A means for fastening newspapers to a back, in temporary cover, or on a desk, so as to preserve them in a convenient condition for reference. See PAPER-FILE.

News'pa-per-file. A clamp to hold newspapers by the folded edge in convenient condition for reference and preservation. The two rods spring apart, but are retained by a hook. See PAPER-CLAMP.

News'pa-per Fold'ing-ma-chine'. A machine for folding newspapers for mailing. See FOLDING-MACHINE.

New-to'ni-an Tel'e-scope. A form of the reflecting-telescope, in which the rays are reflected from the surface of the object-mirror and intercepted by a small oval mirror placed in the axis of the tube at an an-

Digitized by Google

gle of 45°. The image which would have been formed in the axis is thereby deflected and is viewed by an eye-piece attached at a right angle to the side of the tube. See REFLECTING-TELESCOPE.

The small mirror is fixed on the end of a slender arm connected to a slide, by which it is made to approach or recede from the large speculum, as may be required. See TELESCOPE.

Nib. 1. (*Husbandry.*) The handle of a scythe-snath. It has a ring slipping on the snath and tightened by a bolt or wedge.

2. (*Locksmithing.*) A separate adjustable limb of a permutation key.

3. *a.* One of the points of a pen. Pens have usually two nibs, but Perry's have three.

b. A small pen adapted to be placed in a holder for use. The usual form of steel pens. Quill nibs are also made and similarly held for writing. Such *quill nibs* have no *barrel*, as the cylinder of the quill is called. Steel pens having a cylindrical shape to hold on to a round stick are called *barrel-pens*.

4. The point of a crow-bar.

Nib'bling. (*Lens-making.*) Reducing a blank of glass to roundness preparatory to grinding it for a lens. The operation is performed by a pair of flat pliers of soft iron, called *shanks*, which crumble away the edge of the glass and do not slip, as tools with steel jaws would be apt to do.

Niche. (*Architecture.*) A hollow or alcove in the face of a wall for a statue, clock, etc.

Nick. 1. (*Printing.*) The notch on the bottom edge of the shank of a type, forming a guide to the compositor in *setting*.

2. The slit in the head of a screw at which the screw-driver is applied.

3. A notch or incision at a measured distance on an object. A cut to form a starting-point for a kerf.

Nick'el. Equivalent, 29.6; symbol, Ni.; specific gravity, 8.279, which is increased by hammering to 8.82. Fuzes at about 2,800° F. A brilliant, silver-white, ductile metal discovered by Cronstedt in a mineral derisively termed by the miners *nick* or *copper-nick*, on account of its resembling copper ore in appearance, but disappointing them by yielding no copper.

Its ores are found in many parts of the world; in America they have been discovered in Massachusetts, New York, New Jersey, Pennsylvania, Connecticut, Tennessee, Missouri, and Canada. The principal are smaltine or smaltite, from which smalts, zaffre, and cobalt are also extracted; the residue after calcination, called *speiss*, yields some 50 per cent of nickel. Copper nickel contains about 45 per cent of nickel and a large amount of arsenic.

Millerite, a sulphide of nickel, containing 65 per cent of nickel and 35 per cent of sulphur, is found in New York and Pennsylvania, and is largely mined in the latter State.

Pyrrhotite, a species of sulphide of nickel, though containing but a small percentage, from 3 to 6 per cent of the pure metal, is so abundant and widely distributed as to constitute a principal source of supply.

The metal is also found in meteorites in proportions varying from 1 to 20 per cent.

Nickel acts upon the magnet, but more feebly than iron; when heated to 350° F. it loses this power.

Its chief use is in alloys and for plating. It enters into the composition of albata, packfong, or tutenag, German-silver, and numerous other alloys having specific names conferred by their compounders.

The common varieties have 3 to 4 parts nickel; 20 copper; and 16 zinc.

The finer varieties, 5 to 6 parts nickel; 20 copper; 8 to 10 zinc. (See ALLOY.) The pure metal is used for plating, and some of its alloys, containing a large proportion of the metal, for small coin.

In the ordinary process of reducing nickel, the ore is coarsely ground and roasted, mixed with ground fluor-spar, and treated with three times its weight of sulphuric acid, being at the same time gently heated and agitated in a leaden vat. Any hard mass resulting is broken into small pieces, calcined in a reverberatory furnace, and dissolved in hot water, extricating the sulphate of lime. The solid residuum contains several metals, which are separated by first dissolving it in a mixture of nitric and sulphuric acids, and allowing it to stand until crystallization ensues; the crystals are now dissolved in water, and the iron precipitated by carbonate of soda; copper is precipitated by a current of sulphureted hydrogen gas, and cobalt is separated by chlorine, which forms a chloride of nickel, leaving the cobalt free. The chloride is then treated with bicarbonate of soda in solution, evaporated and dried and calcined. The carbonate of nickel thus formed is mixed with charcoal and fluor-spar or other flux, and exposed to intense heat, which produces the metal in a state sufficiently pure for ordinary purposes. It may be obtained chemically pure by the application of a jet of hydrogen gas to the carbonate in process of reduction.

Nick'el-plat'ing. The surfacing of metals with nickel to render them less liable to oxidation by heat or moisture. The operation is effected by a heated solution or in the electro-bath. It has been applied to many articles, such as gas-tips, barrels, and other metallic portions of fire-arms, sieves exposed to water, culinary vessels, type-facing, buckles, and other hardware, buttons, etc., etc.

Kirwan, in 1782, precipitated nickel from its solutions. He says: "Zinc precipitates nickel from the marine acid. Iron clearly precipitates nickel from the nitrous acid." (*Phil. Trans*, Vol. LXXVII. pp. 73–84.)

Golding Bird in 1837 describes the electro deposition of nickel and other metals by the action of long-continued currents of low tension. (*Phil. Trans*, Vol. CXXVII. pp. 37–45.)

Shore, 1840, used a solution of nitrate of nickel in one compartment of battery, and weak sulphuric acid and zinc in the other, for deposition of nickel.

An alloy of nickel and tin made by melting under borax and glass was used for coating iron plates by Richardson and Braithwaite, 1840. The alloy was applied melted, as in tinning iron.

Alfred Smee made an electro deposition of nickel in 1841. (*Smee's Elements of Electro-Metallurgy.*)

Böttger, in the "Journal für Praktische Chemie," Vol XXX. p. 267, 1843, says that among all the salts of nickel the ammonio sulphate of protoxyde of nickel is especially useful in plating brass and copper, and is much superior to cyanide nickel of potash, as recommended by Ruolz. He proceeds at some length to state the effectiveness of the battery in producing a deposit of nickel on copper in half an hour, which would deflect the needle, and preserve the lower metal from the effect of nitric acid more perfectly than a coating of gold deposited in the same time.

Parkes, 1845, melted an alloy of nickel with a flux for coating metal plates.

Junot, 1852, alloyed silicum, titanium, tungsten, etc., with nickel for electro deposition.

Thomas, 1864, used ferro-cyanide of potassium and nitro-muriatic acid to obtain a nickel solution for the battery. In 1855 he used the same, with carbonate of ammonia and oxide of alumina.

Cheatley, 1855, deposited alloys of nickel by a battery (British patent 1543, of 1855).

An alloy of nickel was applied to iron plates by friction and heat by Barron in 1856.

Shepard, 1858, deposited an alloy of silver and nickel. The solution is made by adding carbonate of ammonia to a solution of nitrate of silver, then a similar solution of carbonate of nickel in carbonate of ammonia. An anode of one part silver and two parts nickel is used. Cyanide of potassium may be used in the battery.

Adams, United States patent No. 57,271, 1866, coats gas-tips with nickel. Same. 1869, uses solution of sulphate of nickel in solution of sulphite or bisulphite of ammonia. Same, 1869, effects electro deposition by a solution of double sulphate of nickel and ammonia, free from acid or alkaline reaction. He

Digitized by Google

uses a nickel and iron anode His patent, No. 102,748, claims the use of a nickel anode combined with carbon. Patent of 1871 uses a heated battery

Dr Adam's process consists in the deposition by electro-magnetic agency of metallic nickel from either of three solutions: — 1, one formed of the double sulphate of nickel and alumina; 2, of the double sulphate of nickel and potash; 3, of the double sulphate of nickel and magnesia.

These solutions are preferably used at a temperature above 100° Fah., and must be so prepared and used as to be free from any acid or alkaline reaction. For this purpose care must be taken to avoid the use of too high a battery power or the introduction of any foreign matter into the solution.

In Nagel's process, two parts of sulphide of the protoxide of nickel and one of ammonia are combined to form a double salt: this is dissolved in water, and a solution of ammonia added. The deposition is effected by a battery having a platinum positive pole, the solution being heated to about 100° Fah. Coating with cobalt is effected in an analogous way.

It has been proposed to color the nickel during deposition from a similar solution by using two anodes, one of iron, the other of nickel. If the coating indicates an excess of either metal, the corresponding anode is raised partially or wholly from the solution until the proper combination is produced.

Nickeling. Professor Sharples says: "The double sulphate of nickel and ammonium, which is the salt that is generally used, may now be had in commerce almost pure. Cast-nickel plates for anodes may also be obtained. The anodes should considerably exceed in size the articles to be covered with nickel. Any common form of battery may be used. Three Daniell's or Smee's cells, or two Bunsen's, connected for intensity, will be found to be sufficient The battery power must not be too strong, or the deposited nickel will be black. A strong solution of the sulphate is made and placed in any suitable vessel: a glazed stoneware pot answers very well, if the articles to be covered are small. Across the top of this are placed two heavy copper wires, to one of which the articles to be covered are suspended, to the other the anode. The wire leading from the zinc of the battery must then be connected with the wire from which the articles are suspended, the other battery wire being connected with the anode.

"In order to prepare the articles for coating, they must be well cleaned by first scrubbing them with caustic soda or potash, to remove any grease, and then dipping them for an instant in *aqua regia* and afterward washing thoroughly with water, taking care that the hand does not come in contact with any part of them. This is accomplished by fastening a flexible copper wire around them, and handling them by means of it The wire serves afterward to suspend them in the bath.

"If the articles are made of iron or steel, they must be first covered with a thin coat of copper. This is best done by the cyanide bath, which is prepared by dissolving precipitated oxide of copper in cyanide of potassium. A copper plate is used as an anode. After they are removed from the copper bath, they must be washed quickly with water and placed in the nickel bath; if allowed to dry or become tarnished, the nickel will not adhere

"Great care must be used through the whole process to keep all grease, dust, or other dirt from the articles to be covered, or else the result will be unsatisfactory. The whole process is one of the most difficult that is used in the arts, it being far easier to gild, plate, or copper an article than to nickel it; but if due care be taken, the results will amply pay for the trouble." — *Boston Journal of Chemistry.*

Martin and Delamotte propose to use nickel salts with organic acids instead of those generally employed. The bath is prepared by dissolving 1,250 grams citric acid, 500 grams sal-ammoniac (or sulphate of ammonia), and 500 grams nitrate of ammonia in 15 liters of water. The solution is heated to 80° C., and gradually saturated with freshly precipitated hydrated protoxide of nickel. The heat is then removed, 2½ liters of ammonia added, and water enough to make 25 liters, so that each liter of the bath contains about 50 grams of nickel. When cold, 500 grams carbonate of ammonia is added, the sediment allowed to settle, and filtered. The bath has a blue-black color, stands at 11° B., and is used at a temperature of about 50° C. Caustic potash or soda gives a thicker deposit.

In Professor Stolba's process, a quantity of concentrated chloride of zinc solution is placed in a clean metallic vessel, and to this is added an equal volume of water. This is heated to boiling, and hydrochloric acid is added drop by drop until the precipitate which has formed on adding water has disappeared. A small quantity of zinc powder is now added, which produces a zinc coating on the metal as far as the liquid extends. Enough of the nickel salt (chloride or sulphate) is then added to color the liquid distinctly green; the objects to be plated are placed in it, together with some zinc clippings, and the liquid is brought to boiling. The nickel is precipitated in the course of fifteen minutes, and the objects will be found to be completely coated. The coating varies in luster with the character of the metallic surface; where this is polished, the plating is likewise lustrous, and *vice versa*

Nick'er. The cutting-lip at the circumference of a center-bit, which cuts in the wood the circle of the hole to be bored. The lip which removes the wood is the *router.*

Nick'ing-bud'dle. (*Metallurgy.*) A form of buddle used in washing lead ore.

Nick'ing-file. A thin file for making nicks in heads of screws.

Nick'ing-trunk. (*Metallurgy.*) A tub in which metalliferous slimes are washed. At the upper end is a trough which discharges a gentle sheet of water over a *nicking-board,* which divides the water into rills and gradually washes off the slimes, settling them on the flat surface of the table in the order of their respective gravities.

Nidged. Nigged; as ashlar.

Ni-el'lo. A method of engraving on gold or silver, which consists in running in along the engraved lines, while hot, a composition called *niello,* composed of silver and other metals more fusible than silver, as lead, copper, etc. This compound is of a black color. This ancient art was revived by the Italians about four centuries since, and in the practice of taking proofs of the work the art of copperplate printing was discovered. The suggestion seems first to have been improved by Tomasso Finiguerra.

The art is still practiced as a mode of ornamenting metal ware, but its principal use is in door-plates, plates for shop fronts, etc., in which the brass or zinc plates are engraved and the depressions filled with wax.

Nig'ged Ash'lar. (*Masonry.*) A building stone roughly dressed with a pointed hammer.

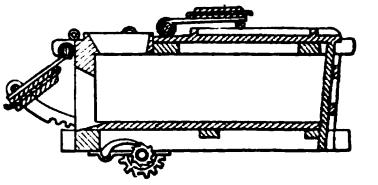
The tool is called a *scabbling-hammer,* and the operation *nigging* or *nidging.*

Nig'ger. (*Steam-engine.*) A steam-engine employed in hoisting; especially on shipboard and on the Western and Southern rivers.

Night-bolt. A spring-bolt in a lock, opened by a knob from the inside of the door, by a key from the outside, but capable of being fastened so as to be immovable from either side.

Night-cart. One employed in carrying away the contents of cesspools and privies. The example is the box of a cart with tightly fitting shutters at the

Fig. 3822.



Night-Cart.

rear part of the box. The upper shutter is held down by levers and holding chains. The discharge-shutter is pivoted at the upper edge and is operated by segmental racks and pinions turned by a hand-lever. The joints are packed to prevent leakage and confine the odor.

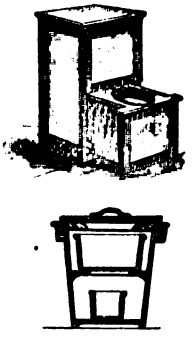
Some forms of carts are loaded by means of pipes and an air-exhaust. Barrels, in some cases, are substituted for cart-boxes, and are filled by means

Digitized by Google

of the pressure induced by the condensation of steam which has previously driven the air from the barrels.

Night-chair. A COMMODE or EARTH-CLOSET (which see) for the sick-room. It is usually made like a chair with a pan in the seat and means for perfectly inclosing the contents, so as to prevent the emission of odor. A common form has a lid whose edge dips into a circular trough around the seat.

Fig. 3328.



Disinfecting Night-Chair.

In the example, the covered pail contains a pan for the feces and one for the disinfectant which deodorizes the mephitic vapors.

Night-latch. A form of door-lock in which the spring-latch may be opened by a key from the outside, or may be fastened shut so as to be immovable from the exterior of the door.

Night-light. A short thick candle with a small wick so proportioned as to burn in a little puddle oil of melted tallow without burning the paper envelope of the cylinder of tallow.

When made of spermaceti or stearine it has no envelope, and the wick is made to bend over in burning, being totally consumed so as not to drop ashes in the tallow. A *mortar*.

Nill. Scales of hot iron from the forge.

Ni-lom'e-ter. An instrument similar to a tide-gage for measuring the rise of the Nile during its periodical floods. One is situated on the island of Er-Rôdah, and consists of a graduated pillar, upon which the hight of the water is read off. The pillar stands in a well which communicates with the river.

The rise of the Nile has always been a subject of great anxiety in Egypt, as upon the periodical saturation of the ground and the coating of soil which is left upon it, the success of the year's husbandry depends.

From the earliest historic period nilometers have been placed in prominent positions in Egypt, to enable the officers to watch the rise, which was proclaimed by criers.

Asama (a governor of Egypt under the Khalif Suleiman) erected the nilometer in the vicinity of what was afterward Grand Cairo, year Hegira 97.

"Citizen Langles has been employed in examining the various nilometers from Alouyah, above the cataracts, to Lower Egypt. He finds 15 between the isle of Elephantina and the mouth of the Nile." — *Nat. Institute of France*, 1800.

The rise seems to have been less in former times than now. In the days of Mœris it is said that 8 cubits were sufficient; 15 or 16 were required in the time of Herodotus, 456 B. C. At the present day 18 cubits is considered the lowest inundation at Cairo.

Hear the "Father of History": —

"One fact which I learnt of the priests is to me a strong evidence of the origin of the country. They said to me that, when Mœris was king, the Nile overflowed all Egypt below Memphis, as soon as it rose so little as 8 cubits. Now Mœris had not been dead 900 years at the time when I heard this of the priests; yet at the present day, unless the river rise 15 or 16 cubits, it does not overflow the lands. It seems to me, therefore, if the land goes on rising and growing at this rate, the Egyptians who dwell upon Lake Mœris, in the Delta (as it is called), and elsewhere, will one day, by the stoppage of the inundations, suffer permanently the fate which they told me they expected would some day or other befall the Greeks. On hearing that the whole land of Greece is watered by rain from heaven, and not, like their own, inundated by rivers, they observed, 'Some day the Greeks will be disappointed of their grand hope, and then they will be wretchedly hungry,' as much as to say, 'If God shall some day see fit not to grant the Greeks rain, but shall afflict them with a long drought, the Greeks will be swept away by a famine, since they have nothing to rely on but rain from Jove, and have no other resource for water.'" — HERODOTUS, II. 13.

Wilkinson, very unreasonably as it would appear, combats the idea of Herodotus, and states that the rise at Memphis has always averaged about 16 cubits; say 40 at Assouan, 36 at Thebes, 25 at Cairo, and 4 at the mouth of the river. See Wilkinson's "Herodotus," Am. ed., 2d Vol., pp. 252 – 254.

In the time of Pliny 12 cubits were a famine, 13 a scarcity, 15 was safety, 16 plenty. At the present day, 18 cubits is the lowest, and at this hight the canals are cut and distribution commences; 19 cubits are tolerable, 20 adequate, 21 excellent, 22 abundant, and 24 ruinous, as invading the houses and stores of the country.

The nilometer at Cairo has been erected for many centuries, but it is not nearly so ancient as that at Elephanta, which consists of a staircase between two walls descending to the Nile. One wall has engraved upon it a series of marks representing the hight to which the water has risen on certain occasions. The cubits here are divided into 14ths, or double digits, and measure 1 foot 8.625 inches. This nilometer was described by Strabo, 54 B. C.

The nilometer at Memphis was transferred by Constantine to a church in the vicinity of the Serapeum of Alexandria; Julian sent it back to the building at Memphis, where it remained till its destruction by Theodosius.

At the present day the rise is watched for with anxiety, and proclaimed by 4 criers.

The object of the nilometers formerly was to settle the amount of taxation to be imposed upon the country. It may still be the basis of the impost of taxes in that overridden country. *Eminent domain* there includes the land, the poor fellahs upon it, and the water.

The effect of the rise is a gradual elevation of the soil of the country, amounting to about 6 inches in a century at Elephanta. The land at that point has been raised 9 feet in 1,700 years; at Thebes about 7 feet, and less toward the Delta, where the periodical rise is about 4 feet. Many of the sites of antiquity are buried beneath the surface, and some of the ancient buildings yet remaining, which were originally placed outside of the cultivatable land, are now surrounded by arable tracts.

The cause of the inundation is the water that falls in Abyssinia in the rainy season. Homer and the Koran are right in ascribing it to water sent by God from heaven.

Calisthenes, the pupil of Aristotle, and afterward Agatharcides of Cnidus (2d century B. C.), and Strabo, ascribed it to the same true source, — the rainy season in Ethiopia.

The rainy season in Ethiopia commences (Kenrick) about the spring equinox and prevails till after the summer solstice. The Upper Nile of course first

Digitized by Google

feels the rise; at Khartoom early in May; at the Cataracts about the first of June. It becomes visible in Egypt about the middle of June. About the middle of August half the rise is attained, and the dikes are then cut; the rise occupies about 100 days, as stated by Herodotus. The maximum is about the 25th of September. After remaining stationary for 12 or 14 days, it commences sinking, and is within its banks again about the 10th of November. Its minimum stage is about the middle of May; the depth at Cairo is then about 6 feet.

The increase of the Nile during inundation is 9-fold its quantity during an ordinary stage. The rate of flow during inundation is 6 feet per second at E' Sinout, about the middle of Egypt; during low water the rate of flow is from 1½ to 2 knots per hour. The immediate banks of the river are seldom covered, and serve as highways. The general breadth of the river is about ⅛ of a mile. It receives no tributaries after leaving Abyssinia, and consequently does not increase in size.

A *low* Nile causes famine. We read of such in Genesis; one A. D. 1200, cited in Abdollatiph's History of Egypt; two in 1784–85, mentioned by Volney. The latter was very destructive, and was caused by light rainfall in Ethiopia. Multitudes sought food in Palestine and Syria.

Nine-pin Block. (*Nautical.*) A block whose shell is spindle-shaped, resembling one of a set of nine-pins. Its ends are swiveled in an upper and lower bar, so that the plane of the sheave may be presented in any direction. It acts as a fair-leader under the cross-pieces of the bitts.

Fig. 3324.

Nine-Pin Block.

Ni-o'bi-um. Symbol, *Nb.* A rare metal, not specially useful in the arts. Once called *columbium.*

Nip. (*Mining.*) The gradual approach of the strata above and below a seam and terminating it.

Nip'per. (*Nautical.*) Strong seizings for binding the messenger to the cable, to form slings, etc. They are made from clean unchafed yarns drawn from unlaid rope.

Nip'per-gage. (*Printing.*) A ledge adjustable on the tongue of the feed-board of a power-press. Used in keeping the required margin uniform.

Nip'pers. 1. A grasping tool with cutting jaws. *b c d e f* show several forms with various presentations of the blades.

2. (*Dentistry, etc.*) The mechanical forceps or nippers used by dentists are for operating on the plates. The following cuts of the operative portions will explain their construction.

g, nipper for cutting off chambers and cutting off backings from plates.

h, nipper for cutting out plates.

i, punch for rivet-holes.

j, plate-bender for upper plate.

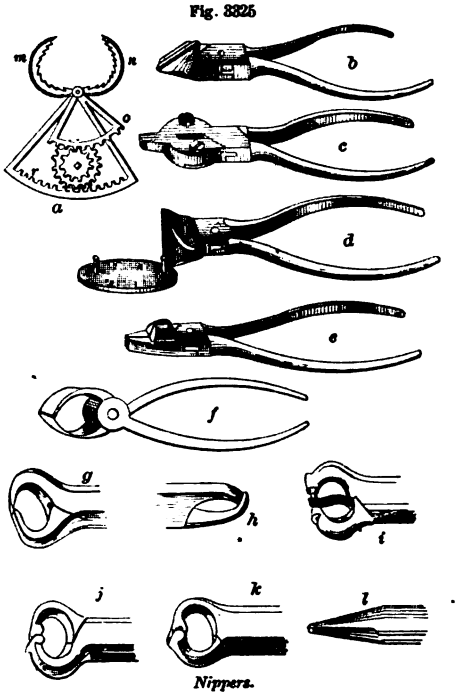
k, plate-bender for lower plate.

l, clasp-bender.

3. (*Hydraulic Engineering.*) Nippers (*a*) for cutting off the heads of piles under water consist of two serrated jaws *m n*, one attached to the small sector *o*, and the other to the large sector *r*. On each sector is a cogged arc engaged by two pinions on an axis which is perpendicular to the plane of oscillation of the nippers. A rotary reciprocation is imparted to the nippers, which cuts off the pile, the jaws being gradually approached by rotation of the axis and pinions as the teeth bury themselves in the wood.

4. (*Printing.*) The clasps which catch the sheet and conduct it to the form.

Fig. 3325



Nippers.

5. (*Wire-drawing.*) The tool for pulling the wire through the plate.

6. Hand-cuffs or foot-shackles for prisoners.

Fig. 3326.

Police Nippers.

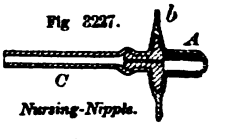
Nip'ple. 1. (*Machinery.*) A small, rounded, perforated protuberance; as the nipple of a gun on which the percussion-cap is placed. A *teat.*

Solid, it is a stud, boss, knob, button.

2. The teat of a nursing-bottle.

Nip'ple, Ar'ti-fi'cial. 1. A concave shield of hard wood, ivory, or india-rubber, fitted to the breast. Inserted in its center is a cup to cover the nipple, made of india-rubber or prepared cow's teat. It is used by women with sore breasts as a protection, to prevent babies biting the nipple while sucking. A *nipple-shield.*

Fig 3227.



Nursing-Nipple.

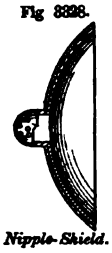
2. A nipple attached to a milk-bottle for the infant. The nipple *A*, shown in the example, has a stop-flange *b* to keep it from passing too far into the infant's mouth. A perforated button is a means of attaching the india-rubber tube *C* to the nipple.

Nip'ple-seat. (*Fire-arm.*) The *hump* on the side of a barrel on which the nipple is screwed and through which the fire is carried to the charge.

Nip'ple-shield. One for the protection of the mother's nipple, that it may not be bitten by the nursing infant. It has a cap of horn or vulcanite,

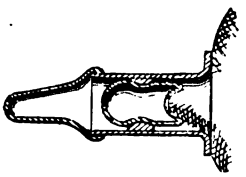
Digitized by Google

Fig 3328.



Nipple-Shield.

Fig. 3329.



Artificial Nipple and Shield.

and the nipple-shield is a fine, elastic, perforated membrane of india-rubber.

Or, as in Fig. 3329, the interior adjustable sliding screen limits the elongation of the nipple when suction is applied.

Nip'ple-wrench. (*Fire-arm.*) The spanner with sides which fit the square of the nipple, and which is used for screwing it to and unscrewing it from the barrel.

Ni'ril. The vibration or chattering of a turning-tool not accurately centered or fitted.

Ni'tric-ac'id Fur'nace. The nitric-acid furnace consists of a number of parallel horizontal cast-iron retorts, arranged in pairs, which connect by luted tubes with a series of receivers and two-necked Woulfe-bottles, wherein the fumes are condensed and collected.

The retorts are charged with nitrate of potash or soda and sulphuric acid. The resulting sulphate is scraped out after removing the end of the retort.

In the *gallery-furnace* the retorts are sunk in sand-pots whose lower surfaces are exposed to the heat of the furnace fire.

Ni-trine'. An explosive compound patented by Nobel, August 14, 1866; formed of glycerine, sulphuric and nitric acids, free of hypo-nitric acid.

Ni'tro-gly'cerine. *Nitroleum, glonoin,* or *blasting-oil.* Discovered by Sobreso, professor of applied chemistry at Turin, in 1847, and introduced into this country in 1864 by Nobel, a Swedish engineer.

An oily liquid of a specific gravity of 1.6, having a sweet aromatic taste, colorless when pure, but, as manufactured, it is usually light yellow. If heated up to 100°, no change takes place; heated gradually to 193°, it is decomposed, losing its explosive power. When not under pressure it burns quietly. Heating when confined may create a partial decomposition, and an explosion from the pressure thus generated. An electric spark will pass through it without causing explosion unless a series of sparks are passed through it until decomposition is caused and heat generated. Fire alone ordinarily will not explode it. Jarring nitro-glycerine, even when at a temperature of 50° C., will not explode it. Explosions occur: 1. When confined and heated to 180° C.; 2. If struck so as to create heat and pressure: percussion causes it to explode with difficulty when frozen, which takes place at 8°, but striking it when in that state with a sharp hard substance, as a pick, will then easily explode it. — *Journal of Applied Chemistry.*

It is prepared by successively adding small quantities of glycerine to a mixture of nitric and sulphuric acids and pouring the compound into water, when the nitroleum, which is insoluble in and heavier than water, falls to the bottom of the vessel.

The acids used should be of the purest quality, and great care taken to avoid the introduction of foreign matters; otherwise slow decomposition, which may finally result in spontaneous explosion, occurs. For this reason it is better to have it made on the spot and used soon after making.

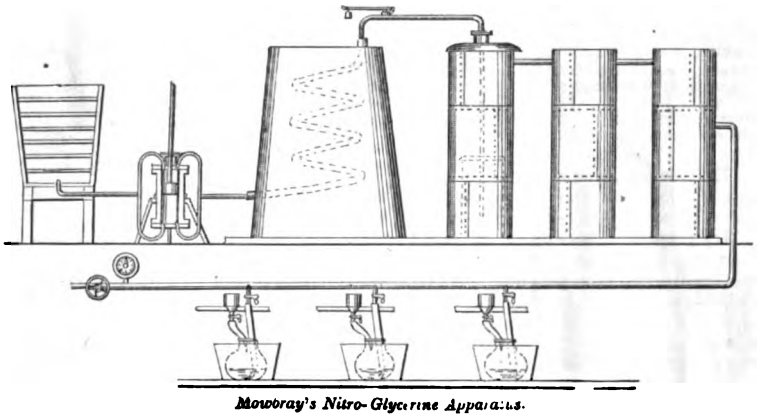
It may be purified by dissolving it, very gradually and at a temperature not exceeding 50° F., in sulphuric acid, and separating the nitroleum by the gradual addition of nitric acid, and then pouring, in a fine stream, into pure cold water from which the air has been expelled by boiling; in the preparation the temperature of 50° should in no case be exceeded.

In Mowbray's process, a current of cold, dry air is passed through the vessels in which the compound is made, for carrying off the hypo-nitrous acid and to cool and agitate the mixture.

The vessels are lined with glass.

This substance has been extensively used for blasting purposes; in the Mt. Cenis and Hoosac tunnels, the operations at Blossom Rock, harbor of San Francisco, in the improvements of the East River, New York, and elsewhere. (See BLASTING; TUNNEL.) Developing about ten times the explosive power of gunpowder, it requires far less drilling and operates so as to lift the rock from its bed without shattering it to such an extent. The number of fatal explosions resulting from it have been an obstacle to its more general use, but these are claimed to have resulted generally from improper manufacture, exposure to too great heat in transportation, or carelessness in handling.

Fig. 3330.



Mowbray's Nitro-Glycerine Apparatus.

Among the most prominent accidents occurring from these sources were the explosions at Aspinwall and in the office of Wells, Fargo, & Co. at San Francisco, by the former of which forty-five and by the latter six lives were destroyed. In the case of the Aspinwall disaster the nitroleum had been shipped from Hamburg, where the temperature was 55° or 60° to a tropical climate where the temperature in the hold of the steamer was probably more than double this. It was inclosed in cork-stopped vessels, packed in cases with sawdust. The explosion has been attributed to the disengagement of gas, which,

Digitized by Google

by the corrosion of the corks, escaped into the surrounding sawdust, forming a new and easily ignited compound, which, becoming mixed with the undecomposed nitroleum which escaped, was easily exploded at such a high temperature by the rough handling to which it was subjected by the stevedores. The sheriff, surveyor, and four other persons were killed by an explosion at Newcastle on Tyne, England, while engaged in burying some cases of this compound in a pit beyond the city limits for safety.

It is noticeable that most of the accidents recorded have occurred in moving, transporting, or liquefying the compound after congelation, and not in blasting.

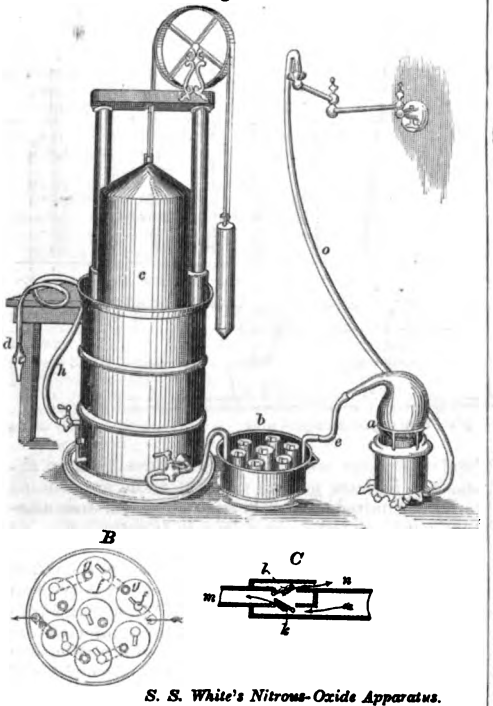
Ni-tro'le-um. A name for NITRO-GLYCERINE (which see).

Ni-trom'e-ter. An instrument for detecting the quality of niter.

Ni'trous-ox'ide Ap'pa-ra'tus. Nitrous oxide (N O), commonly called laughing-gas, is frequently employed in dental surgery as an anæsthetic. It may be procured by simply heating nitrate of ammonia, or by the action of nitric acid on copper or mercury.

Fig. 3331.



S. S. White's Nitrous-Oxide Apparatus.

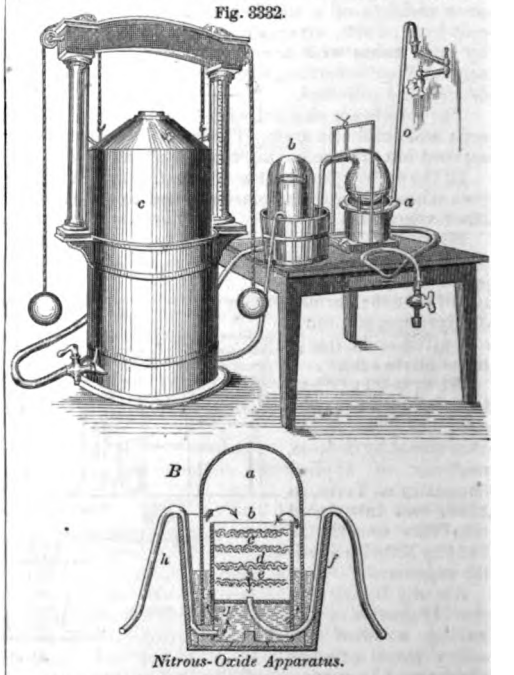
The apparatus shown in Fig. 3331 is designed for the production and retention of this gas on a large scale, for the purpose of inhalation.

It consists of a retort and heater *a*, purifier *b*, gasometer *c*, which may contain 40 to 50 gallons, and inhaler *d*. The gas generated in the retort passes through the pipe *e* to the purifier *b* containing a solution for removing impurities; in this are arranged seven inverted tumblers, shown in plan at *B*, through which the gas successively passes from one to another by the pipes *f g*; on leaving the last tumbler it is received into the gasometer *c*.

The inhaler *d*, shown in section at *C*, is connected by pipe *h* with the gasometer, and has two valves *k l* opening in opposite directions. On applying the mouth to the end *m* and making an inhalation, the valve *k* opens, while during the act of expiration it closes; the valve *l* is at the same time opened, allowing the gas, which has passed through the lungs, to escape through the opening *n*. *o* is a pipe conveying gas to a burner which heats the retort.

The general arrangement of the apparatus shown in Fig. 3332 is identical with the foregoing, but the purifier *B* consists of a glass dome *a* covering the cylinder *b*, which has several disks *c d e* of wire-gauze on which lime is placed for absorbing impurities. The gas enters through the pipe *f* opening above the diaphragm *g*, and circulates, as indicated by the arrows, through the cylinder *b*, finally passing into the gasometer by the pipe *h*.

Fig. 3332.



Nitrous-Oxide Apparatus.

Johnston Brothers of New York furnish liquefied nitrous-oxide gas for dental purposes. They compress 1,200 gallons of gas into a cylinder 24 inches long and 6 inches in diameter; or over 100 gallons into a cylinder 12 inches long, 3½ in diameter. The pressure is about 800 pounds to the square inch at 60°. It is shipped in chilled wrought-iron bottles with steel faucets.

Nob. A head; a knob.

(*Artillery.*) The plate under the swing-bed for the head of an elevating screw.

Digitized by Google

Nobert's Test-plate.

"F. Nobert, a manufacturer of optical instruments, residing at Barth, Pomerania, has, during the last twenty-five years, been renowned for producing the finest rulings on glass which have hitherto been executed. These rulings are used for two purposes; as a test of the defining power of microscopic objectives, and as a means of determining the wave-lengths of the undulations of the several portions of the solar spectrum.

"Those intended for microscopic use are known as *Nobert's test-plates*. They are executed on the under surface of a piece of exceedingly thin glass (1 200 of an inch thick or less), which is either cemented to a slip of ordinary plate-glass such as is used in mounting microscopic objects, or, in exceptional cases, to another piece of thin glass, about 1 100 of an inch thick, the two being mounted over a circular hole drilled in a thin plate of brass. The latter arrangement is intended to permit the ruling to be illuminated from below by achromatic combinations of short focus.

"When one of these test-plates is examined with the naked eye, it looks as if a single straight line not wider than a hair had been engraved beneath the glass cover, and this when held in the light glows with spectral colors as the plate is moved. If this apparent line be examined with a microscope of adequate power, it is found to be composed of a number of bands, each consisting of a group of fine lines, the distances between which vary according to a fixed rule. Nobert has issued a number of kinds of these plates, which differ in the number of bands and in the distance of the lines of the finest band from center to center. The following are the best-known varieties, arranged in the order of the date of their issue: —

Designation of Plate.	Distance of the lines from center to center, in fractions of a Paris line.*	
	In the coarsest band.	In the finest band.
Ten-band plate	1/1000	1 4500
Fifteen-band plate	1 1000	1/5000
Twenty-band plate	1/1000	1/6000
Thirty-band plate	1 1000	1/8000
Nineteen-band plate	1/1000	1/10000
New twenty-band plate	1 1000	1/20000

* The Paris line is rather longer than the English line. One English inch equals 11.25933 Paris lines.

"Of these, the nineteen-band plate has been most used during the last ten years. The new twenty-band plate has only recently appeared, as will be explained hereafter.

"The following table gives the number of lines in each band of the nineteen-band plate and of the new twenty-band plate, so far as known, with the distance of the lines of each band from center to center, in fractions of a Paris line, and the number of times this distance would be contained in an English inch.

Number of Band.		No. of lines in each band.	Distantia linearum in fractions of Paris line.	No. of spaces to the English inch.
In the nineteen-band plate.	In the new twenty-band plate.			
I.	I.	7	1 1000	11,259
II.		10	1 1500	16,889
III.	II.	13	1 2000	22,519
IV.		15	1 2500	28,148
V.	III.	17	1 3000	33,778

	XX.		1 20000	225,187

"It will be seen by this table that the first ten bands of the new twenty-band plate correspond to the alternate bands of the nineteen-band plate, and that the ten remaining bands are all closer than its nineteenth band, the lines of the twentieth band being just twice as close.

"Long after copies of the nineteen-band plate had found their way to all parts of the civilized world, the lines of the finer bands remained invisible to the most skillful microscopists. This resulted not merely from the closeness of the lines, but also from their extreme delicacy and paleness. Nobert, who was himself unable to see them, supposed that there was a physical reason why lines separated by a distance less than the shortest wave-length of visible light, would forever resist resolution; an opinion which has since been shown to rest upon a misinterpretation of the physical law invoked. In 1869, however, the lines of the sixteenth, seventeenth, eighteenth, and nineteenth bands were not only seen and counted, but they were photographed by Dr. J. J. Woodward and one of his assistants in the Army Medical Museum at Washington, and the feasibility of resolving them was thus placed beyond doubt. Prior to this, various microscopists had believed that they had resolved these bands, but as they had not succeeded in ascertaining the number of lines in each individual band their claims were not universally accepted.

"On the receipt of the Museum photographs, Nobert for the first time acknowledged that the highest four bands had been resolved, and promised that he would endeavor to rule still finer lines. The new twenty-band plate was the result of his subsequent efforts. One of these plates was furnished by him to President Barnard of Columbia College in 1872, and in the spring of 1873 another was received at the Army Medical Museum. Systematic endeavors with the best modern objectives have failed as yet to resolve any of the bands of this plate beyond the tenth, and hence perhaps some will be disposed to deny that they have actually been ruled as stated, but it must be remembered that similar doubts were raised with regard to the finer bands of the nineteen-band plate before they were resolved; and the appearances presented by the new bands are so similar to those of the higher bands of the old plate, when viewed by a power inadequate to resolve them, that it seems probable that Nobert has again succeeded in outstripping the present resolving power of our best microscopes, as he did in former times; that the new bands are actually ruled as claimed, and that they will serve, as the higher bands of the old plate did, a most useful purpose by stimulating practical opticians to still farther improvements in the construction of objectives.

"The method by which Nobert prepares these rulings has been kept secret. Various attempts have been made to imitate them, but without success, because no one else has been able to construct a point suitable for executing such work; the best diamond splints make marks which are ragged and uneven when examined by high powers, and diamond-points, prepared by grinding with diamond-dust in the most careful manner, are yet too coarse to imitate the beauty and regularity of even the lines of the coarsest bands of Nobert's plates. Could a suitable point be prepared, there would appear to be no serious difficulty in constructing a machine to execute the rulings.

"Used, with suitable precautions, as a test of the resolving power of microscopic objectives, the plates of Nobert appear to offer great advantages over diatoms and other natural objects. In the case of the latter, individuals of the same species vary greatly in dimensions and in difficulty of resolution, while in Nobert's plates the variation is reduced to a minimum. The ruling is executed with such marvelous precision that no perceptible differences can be detected in the dimensions or difficulty of similar bands on different plates, and they afford also a convenient means of assigning numerical values to the resolving power of the objectives tested.

"To resolve the highest bands of the nineteen-band plate or the corresponding ones of the twenty-band plate, objectives of the best quality are required, and should be used with oblique illumination. A coal-oil lamp may be employed as the source of light, but the most satisfactory results are attained by using monochromatic (blue) sunlight, which may be obtained by means of a suitable prism, or by reflecting the sunlight from a mirror through a thin layer of a saturated solution of the ammonio-sulphate of copper.

"Any of the test-plates of Nobert can also be used for determining the wave-lengths of light. Nobert has, besides, prepared a variety of plates especially for this purpose. When closely ruled lines on glass are illuminated by an oblique pencil of light, and viewed with a low power of very small aperture, the line of vision being perpendicular to the plane of the ruling, the latter will appear as a colored band, the color varying with the angle which the luminous pencil forms with the plane of the ruling. Now it has been shown that this angle, the wave-length of the color seen, and the distance of the lines apart, stand in a fixed mathematical relation to each other; so that if the distance of the lines is precisely known and the angle carefully measured, the wave-length of the color seen can readily be computed. The fidelity with which Nobert's rulings are executed at the distances stated by their maker gives them a high value for this purpose. One of the most ingenious of these plates is the so-called *wave-plate*, in which there are seven bands, the lines of which stand in such a relation to each other as to distance, that when they are illuminated with light

Digitized by Google

thrown with such obliquity that the first or coarsest band appears red, the second is orange, the third yellow, the fourth green, the fifth blue, the sixth indigo, and the seventh violet. Viewed with a suitably high power these bands are seen simply as groups of fine black lines, the distances of which from center to center can readily be measured by a micrometer.

"For further details with regard to Nobert's plates, the reader may consult F. Nobert in 'Poggendorff's Annalen,' Bd. 58, 1852. The treatises of Carpenter and Harting on the Microscope, and a number of papers published in the 'Quarterly Journal of Microscopical Science,' and the 'Monthly Microscopical Journal,' since 1838."

Kindly furnished for this work by Colonel J. J. Woodward, M. D., United States Army.

Nock. (*Nautical.*) The upper front corner of a 4-cornered, fore-and-aft sail; such as a *spanker*, a *trysail*. Also called the *throat*.

Noc'to-graph. *a.* A writing-frame for the blind.

b. A nightly account or report. The converse of the *diary*.

c. An instrument or register which records the presence of watchmen on their beats.

Noc-tur'nal; Noc'tur-la'bi-um. (*Nautical.*) An instrument to take the altitude or depression of some of the stars about the pole, in order to find the latitude and the hour of the night. — ADMIRAL SMYTHE.

Nod'dy. A small, two-wheeled, one-horse vehicle.

Node. A small hole in the gnomon of a dial to indicate the hour by its light, as the gnomon itself does by its shadow.

Nog. 1. (*Mining.*) One of the square blocks of wood which are piled on one another to support the roof of a mine.

2. (*Building.*) A wooden block of the size of a brick, built into a wall as a hold for the nails of the finishing work which is nailed thereto.

3. (*Shipbuilding.*) A treenail driven through the heel of a *shore* which supports a ship on the *slip*.

Nog'ging. (*Building.*) A wall or partition of scantling with the interstices filled in with brick. Brickwork carried up in panels between *quarters*.

Nog'ging-piece. Horizontal scantling laid between courses occasionally.

Noils. Combings, waste, tangles, and knots of wool removed by the comb.

Non-cir'cu-lar Wheel. A wheel whose perimeter is not circular; a pair of such being used to transmit a variable velocity ratio between a pair of parallel axes. Such wheels may be elliptical, scroll, hyperbolar, etc.

Non-con-dens'ing Steam-en'gine. A steam-engine, usually high-pressure, in which the steam on the non-effective side of the piston is allowed to escape into the atmosphere. In contradistinction to an engine in which the steam in advance of the piston is condensed, to create a partial vacuum and thus add to the effective value of the steam which impels it.

Non-condensing engines are lighter than *condensing* engines of equal power, as the latter contain a large number of bulky and heavy parts of which the other is destitute. Condensing engines are generally more economical of fuel.

The comparative lightness and compactness render the *non-condensing* engine suitable for locomotives and steamboats of light draft. The Western and Southern rivers are comparatively shallow at certain points or seasons, and *non-condensing* engines are used in those sections of the country. The Eastern rivers and Northern lakes are deep, and the *condensing* engine is used thereon.

Pumping and *factory engines* of large size are usually *condensing*. A notable example to the contrary is George Shield's pair of horizontal pumping-engines at the Cincinnati Water-Works. They were put in operation about 1846.

The escaping steam of non-condensing engines is usually made to heat the feed-water. In locomotives it is exhausted into the chimney to increase the draft. This was first done by Trevethick in 1802. It was at first designed probably to put out the sparks, avoid noise, and get rid of the steam without the addition of a second pipe.

The following from Haswell is based upon a uniform steam pressure of 60 pounds per square inch (steam gage), cut off at one half the stroke, deducting one sixth for friction and losses, with a mean velocity of piston of 250 feet per minute: —

Nominal Horse-Power of several Non-condensing Engines.

Non'i-us. A sliding graduated scale on a graduated plate adapted to subdivide the divisions of the scale on which it moves. So called from Peter Nonnez or Nonnius (his Latinized name), a Portuguese mathematician of Alcazar, born in 1497. See VERNIER.

The nonius scale of a quadrant or sextant is fixed to the oblong opening near the lower end of the index-bar. It divides degrees into minutes and these into seconds.

Non-pa-reil'. (*Printing.*) A size of type between agate and minion.

Agate.
Nonpareil, 143 ems to the foot.
Minion, 128 ems to the foot.

Noo'dle. (*Domestic.*) A strip of rolled dough, used in soup.

A noodle-making machine, patented January 13, 1874, has a frame in which two rollers revolve, with a plate between them, which roll out a sheet of dough. Above the upper roller is another, armed with a series of circular disk-cutters that project below slots in a metallic guard. The metallic plate, with the sheet of dough upon it, is passed between the upper plain roller and the roller with the cutters, thus forming the dough into strips.

No'ri-a. A water-raising device (Arabic, *Na' Ura*), which has traveling pots or buckets, submerged below and discharging at their point of greatest elevation.

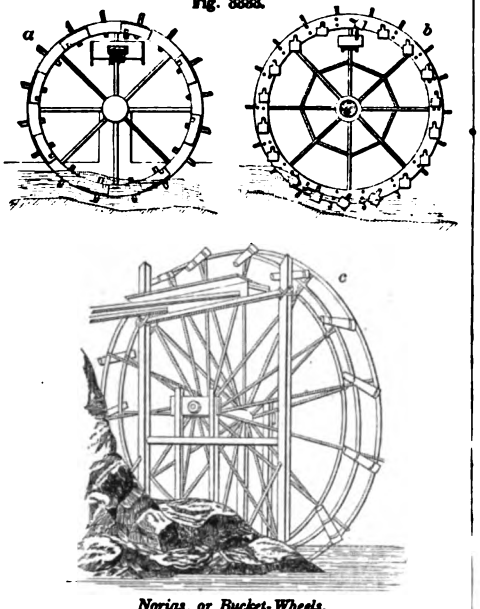
Digitized by Google

The modes of constructing and operating are various: —

1. The original form seems to be a wheel with buckets or pots each pivoted to the rim at a point above its center of gravity, so as to hang perpendicularly. These are submerged in the water at their lowest point, and, rising, are upset by contact with a fixed obstacle at their highest point, discharging into a chute or trough which conducts the water to a reservoir. *a b*, Fig. 3333, show two forms of the device, — a wheel with boxes in its rim, and one with suspended buckets.

The Chinese *noria c* is made of bamboo, excepting the hub of the wheel and the posts on which it rests. The buckets are bamboo tubes, inclined so as to hold nearly to their capacity till they reach their culminating-point. The wheels are from 20 to 40 feet in diameter, according to situation, and are driven by the impinging of the stream upon peripheral float-boards. One described by Sir George

Fig. 3333.



Norias, or Bucket-Wheels.

Staunton was 30 feet in diameter; had 20 buckets, 4 feet long and 2 inches diameter in the clear, holding $\frac{11}{16}$ of a gallon; 12 gallons to a revolution, 4 revolutions and 48 gallons per minute; over 300 tons per day.

The reference to water, and to means for obtaining it, are very frequent in the Bible. In the much-misunderstood text in Ecclesiastes we find a reference to the *noria*: —

"Or ever the silver *cord* be *loosed*, or the golden *bowl* broken, or the *pitcher* be broken at the fountain, or the *wheel* broken at the cistern."

These wheels have been used from time immemorial in raising water for irrigation, in Assyria, Egypt, Persia, Syria, Arabia, and Palestine, and no doubt in China and India, but have undergone many modifications.

Thompson, in his "The Land and the Book," says: "This system of water-wheels is seen on a grand scale at Hums Hamath and all along the Orontes. The wheels there are of enormous size, 80 or 90 feet. They are driven by the river itself, paddles being attached to the rim, upon which the stream is turned by means of a low dam, carrying the huge wheel around with its load of ascending buckets. There is perhaps no hydraulic machinery in the world by which so much water is raised to so great an elevation at so small an expense. With their loads they slowly revolve on their groaning axles, each singing a different tune, — a concert wholly unique and half infernal, which, once heard, will never be forgotten."

The wheel with jars attached is one form of the Roman *antlia*, known by the same name also in Greek.

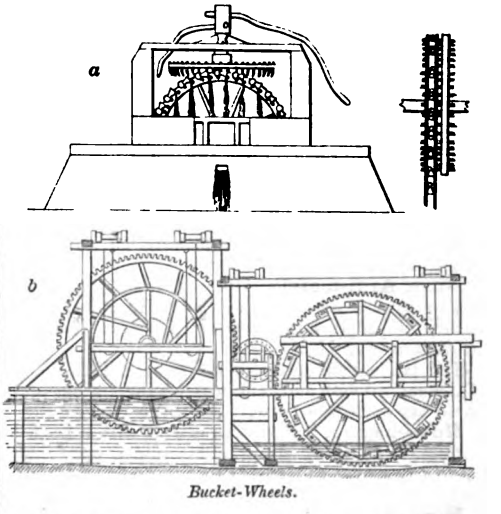
A substantially similar form of wheel is used on the river Eisbach, in the Tyrol; it also is rotated by the force of the current impinging on radial floats on or near the periphery of the wheel.

In other places in the East the wheel is driven by manual or animal power.

Another form of the *noria* is much used in Syria and Palestine, in raising water for irrigation (*a*, Fig. 3334). A central post has a circular sweep-pole, to which a mule is attached. Cogs on the central shaft engage others on a horizontal shaft, and operate the wheel upon which traverses a continuous rope furnished at intervals with jars or wooden buckets. The rope descends on one side with empty buckets and rises on the other side with full ones, which discharge into a chute leading to the cistern. These wheels are kept going day and night by relays of men and mules; in some cases being the joint property and care of the inhabitants of a whole village.

The great bucket-wheel (*b*, Fig. 3334) employed by Perronet at the construction of the Bridge of

Fig. 3334.



Bucket-Wheels.

Neuilly, France, was 16½ feet in diameter, 4½ feet in width, and had 16 buckets and 118 cogs. The water-wheel by which the bucket-wheel was driven was 18 feet in diameter and had 128 cogs. The float-boards were 20 feet long, 3 feet wide, and were set at an angle of 15° with the radius. The lantern-wheels which acted as pinions to the large cog-wheels of the bucket-wheel and water-wheel were 4 feet in diameter and had 30 trundles. The axle of the trundles was 12 inches in diameter, and varied in length according to the relative proximity of the water-wheel and the bucket-wheel. The former was in the Seine,

Digitized by Google

and was rotated by the current of the river; the latter was in one of the coffer-dams which were constructed for the purpose of establishing foundations for the piers of the bridge. The axles of the lantern-wheels varied in length from 38 and 54 to 108 feet.

The term *noria*, having been applied generally to traveling water-raising buckets, has included the chain-pump, which in some treatises is called the *Spanish noria*. A new feature, however, is found in this, namely, a tube up which the pistons — no longer buckets — ascend.

The true Spanish *noria* has earthen pitchers secured between two ropes which pass over a wheel above and are submerged below. See CHAIN-PUMP.

No'ri-um. A metal discovered in combination or in company with zircon, and but little known.

Nor'ma. 1. A square used by carpenters, masons, and others to lay off and test their work.

2. A pattern, templet, gage, or model.

Nor'man. (*Nautical.*) A bar or pin in a hole of a windlass or capstan, or on the cross-piece of the bitts, whereon to fasten or veer a rope or cable.

Nor-we'gi-an Stove. An apparatus which may be used either to retain heat derived from other sources or serve as a refrigerator. It consists of a square wooden box lined with a soft, non-conducting substance; cows' hair is the substance actually employed. The lid is similarly lined. The interior is arranged for one or more saucepans, which, when inserted in the stove, are completely surrounded by the material. The meat or other substance in the saucepan being brought to the boiling-point in the ordinary manner, the pan is inserted in place in the stove, where, the radiation of heat being prevented by the lining, the contents remain at a boiling heat a sufficient time to insure their being thoroughly cooked.

When used as a refrigerator, the lining prevents the access of warm air to the cooler object within. No heat is of course ever applied to the apparatus, which is designed merely to maintain the temperature of an object already heated.

It is only adapted for articles cooked by water or steam.

Nose. 1. (*Machinery.*) A pointed or tapering projection in front of an object.

2. A nozzle, as of a bellows, a pipe, a tuyere.

3. The beak or rostrum of a still.

4. (*Lathe.*) The end of a mandrel on which the chuck is secured.

Nose, Ar'ti-fi'cial. A prosthetic nose, made of india-rubber or gutta-percha, colored in imitation of nature and applied in place of the organ removed by disease or accident.

The taliacotian operation makes an artificial nose of the natural flesh and skin, which adhere to the prepared base and grow there. See RHINOPLASTIC PIN.

Nose-bag. A bag of stout canvas with a leather bottom, and having straps at its upper, open end, by which it may be fastened to a horse's head while he is eating the contained provender.

Nose-band. (*Saddlery.*) The lower band of the military bridle, passing over in front and attached to the cheek-straps. A *musrole*.

Collapsible nose-bands and similar devices to check runaway horses by stopping respiration are described in English patents: —

No. 1,576 of 1858.
No. 1,014 of 1858; pallets to stop nostrils.
No. 2,597 of 1858; pallets to stop nostrils.
No. 529 of 1859
No. 1,184 of 1859; pallets to stop nostrils
No. 1,881 of 1860; pallets to stop nostrils.
No. 13 of 1861.
No. 1,924 of 1831; closing the blinkers.

Nose-bit. Another name for the *pump-bit* or *shell-auger*, used in boring out timbers for pump-stocks or wooden pipes. (See BIT.) A *slit-nose* bit.

Nose-hole. (*Glass-making.*) The open mouth of a furnace at which a globe of *crown-glass* is exposed during the progress of manufacture, in order to soften the thick portion at the neck, which has just been detached from the *blowing-tube*.

Fig 3335.

Double Nose-Piece.

Nose-key. (*Carpentry.*) A fox-wedge.

Nose-piece. 1. (*Optics.*) That which holds the object-glass of a microscope. Double, triple, or quadruple nose-pieces are sometimes attached to the nose of a microscope, and hold as many object-glasses of varying power, which are brought into requisition as desired.

2. (*Harness.*) The nose-band of a bridle.

Nose-pipe. The section of pipe containing the contracted orifice attached to the end of the blast-pipe, and placed within the tuyere of a blast-furnace.

The nose-pipes, through which the air issues into the furnace, vary in size with the nature of the coke and the ore. In Staffordshire they are usually from $2\frac{4}{10}$ to $2\frac{8}{10}$ inches in diameter.

Nos'ing. (*Carpentry.*) *a.* The rounded front edge of a *tread* which projects over the *riser* of a stair.

b. The prominent edge of a molding or drip.

Notch. An indentation cut in an object. A *croze*, for instance.

Notch-board. (*Carpentry.*) The board which receives the ends of the steps and risers in a staircase.

Notch'ing. 1. (*Railroad Engineering.*) A system of carrying forward excavations for railroads by a series of steps, upon which the work is simultaneously proceeding. Also called *gulleting*.

2. (*Carpentry.*) A mode of joining timbers or scantling in a frame. It is either square or dovetailed, and is made use of for connecting the ends of wall-plates and bond-timbers at the angles, letting joists down on girders, binders, sills, plates, or purlins.

Halving, *scarfing*, and *caulking* are forms of notching, and form a *lap*-joint.

Notch'ing-adze. (*Carpentry.*) A light adze with a bit of large curvature or nearly straight for notching into timbers in making gains, etc.

Note. 1. (*Printing.*) These are of three kinds: —

a. Shoulder-notes. At the top of the page, giving book, chapter, and date, as in reference Bibles.

b. Side-notes. Marginal or *set-in* notes, containing abstracts of the text, as in law-books, or reference notes to parallel passages.

c. Bottom-notes. Containing commentaries and annotations.

2. A size of paper.

3. (*Music.*) A character whose shape indicates its duration, and whose place on the staff indicates its pitch.

Nou-e'. (*Surgical.*) A bandage with knots to press upon the parotid region after extirpation of the parotid gland.

Now'el. (*Founding.*) The inner portion of the mold for casting of large hollow articles, such as tanks, cisterns, and steam-engine cylinders of large size. It answers to the *core* of smaller castings. See *loam-work*, under MOLDING.

Noyl. The short refuse left upon the teeth of

Digitized by Google

the combs in preparing long-stapled wool for drawing and spinning. See WORSTED.

Noz'zle. 1. (*Hydraulics, etc.*) A spout or projecting ventage, as of —

a. The fireman's pipe at the end of the hose.

b. The snout of a pair of bellows or a tuyere.

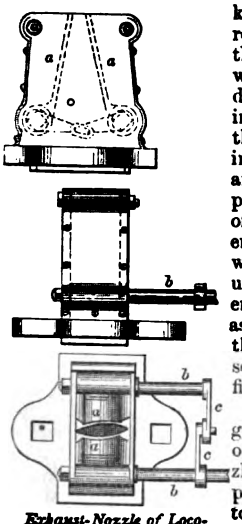
c. The projecting ventage of a faucet, of rain-water spouting, any discharge-pipe, etc., etc.

2. (*Steam-engine.*) *a.* The steam-port of a cylinder.

b. In English practice the *nozzle* includes those portions of a steam-engine in which are placed the valves that open and close the communication between the cylinder and the boiler and condenser in low-pressure or condensing engines, and between the cylinder and boiler and atmosphere in high-pressure or non-condensing engines.

c. The exhaust of *locomotives* and some other engines, such as the agricultural and saw-mill engines, known as *portable*, is directed into the chimney, the original purpose of which was to urge the draft. This was adopted in the locomotive of Trevethick in 1802, by Hedley in his locomotive of 1813, and by several of the competitors at the great trial of locomotives on the Liverpool and Manchester Railway in 1829. It is a valuable feature in agricultural engines, besides its function as a blast, in dampening the sparks which might set buildings or straw on fire.

Fig 3336.



Exhaust-Nozzle of Locomotives.

The locomotive engineer governs his blast by means of a variable exhaust-nozzle, which he opens or partially closes according to the requirements of the engine, its immediate duty, and the state of the fire.

In the illustration the nozzle is shown as having two leaves *a a*, on axes *b b*, which are moved simultaneously by means of the link *c c*, one of the axes *b* being connected to a hand-lever in the cab of the locomotive. For position of the nozzle, see PETTICOAT-PIPE.

Noz'zle-block. One in which two bellows-nozzles unite.

Noz'zle-mouth. The aperture. A *tuyere.*

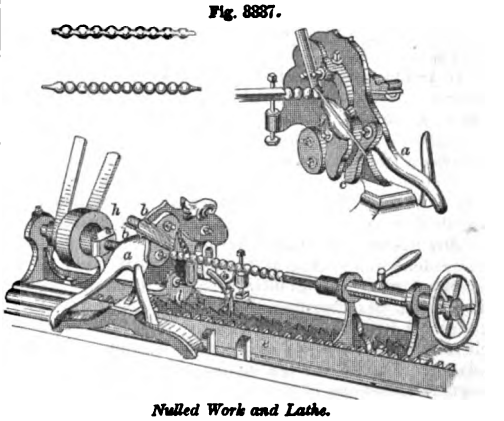
Noz'zle-plate. (*Steam-engine.*) A seat for a slide-valve of a steam-engine.

Nulled-work. Turned work resembling a series of beads strung on a rod. Much used in spindles and rolls for bedsteads, chairs, cribs, and other articles of furniture.

It is made in lathes whose cutter is automatically raised and depressed as the feed-screw draws it along on the bed. Fig. 3337 shows Alcott's lathe with Rennie's attachment. This consists of the lever *a*, with the adjustable knife-holders *b b* and attached arm *c*, back-rest *d* and rack *e*, with which the arm *c* engages.

In operating the machine, the lever *a* is turned up and the carriage propelled forward, the stick being rounded by the knife *g*; the carriage is then brought back to its first position, and by moving the lever up and down, the carriage is, through the arm *c* engaging with the rack *e*, advanced the proper distance and the nulls or beads formed by the cutter *h*.

Fig. 3337.



Nulled Work and Lathe.

A device for forming tenons on the ends of the piece may also be attached.

Num'ber-ing-ma-chine'. A machine for impressing consecutive numbers on account or record books (a *paging-machine*), coupons, railway certificates, bank-notes, railway tickets, etc.

The notes of the Bank of England were numbered by a machine invented by Bramah, 1806. It printed the numbers upon them consecutively at a rate which dispensed with the labor of 100 clerks out of 120 who were detailed for that duty during the issue of £1 notes.

The foundation idea is that of Blaise Pascal (1650), and consists of disks or wheels decimally numbered on their peripheries, the whole mounted on one axle, upon which they turn freely, acting upon each other in serial order, as explained under ARITHMOMETER. The first wheel of the series containing the units is moved one figure between each impact, and when the units are exhausted the tens come into action, and act in coincidence with the units, which continue their action. So on of the 100s, 1,000s, etc.

Bramah's numbering-machine, improved by Oldham, had 5 brass circles with studs carrying the numerals, so as to be able to number up to 99,999. The bank-note was presented on a table above, and the tympan brought down upon it, forcing the paper against the numbered studs, which were presented through openings in the bed. After each impression the first wheel of the train was rotated one spoke, bringing the next unit into presentation. The unit-wheel acted upon the 10-wheel as soon as the number 9 was reached and printed; the 10-wheel acted upon the 100-wheel, and so on, as seen in Watt's *registering-machine*, *gas-meters*, *arithmometers*, and numerous analogous machines and contrivances. The type-wheels were inked by a *dabber*. The machine had several crude movements, but is interesting as among the first of the automatic shifting instruments for serial indications or work, including the modern numbering and paging machines, calculating-machines and registers, the indicating-apparatus of meters, etc.

Trouillet's numbering-machine (French) is adapted either for hand or for use in a press. It consists of an axle containing a number of wheels, having on their perimeters the ten numerals separated by spaces. An instrument with 6 wheels will number from 000,001 to 999,999. The position, after every impact, is changed by means of a small lever that

Digitized by Google

rises alongside of the wooden handle, the immediate change being on the unit-wheel, and that acting upon the 10-wheel as its own numerals become exhausted, and it prepares to commence again at 1. So on with the 10 and 100 wheels to the end of the series.

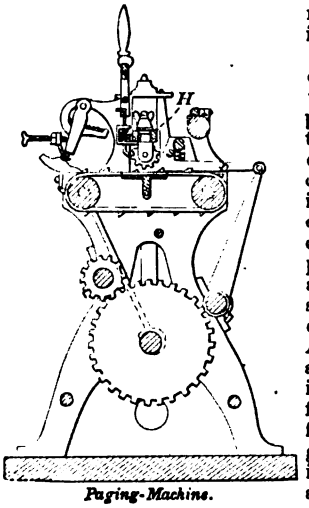
In the machine used in the Bank of France each note receives five impressions from the machine at once, distinctive of its relations to the remainder of the issue. One of these is its number of order, and increases from note to note; the others are significant of the class or of the particular series to which the note belongs, and change with the commencement of each new series. It is entirely automatic, taking up each note separately from the supply on one side, transporting it to the printing-table to be stamped, and subsequently removing it and depositing it in the receptacle for finished notes. The notes are lifted by a gentle force of aspiration produced by an air-pump, and acting through a hollow plate perforated on the under side, and having a regular succession of movements.

Bailey's machine is designed for imprinting successive numbers on railway-tickets and their coupons at one operation. It also partially separates the coupons from each other and from the ticket, so that they may be readily torn apart.

Edmonson's prints the names of places on tickets, at the same time numbering them consecutively. The cards are fed singly to a horizontal table under a type-box containing the form, which is vertically reciprocated to receive ink from the rollers and to print the cards, which are held in place by guides extending from the feeding-tube to the receiving-tube. The numbers are engraved on the peripheries of wheels by which they are impressed on the cards.

Hoe's machine has peculiar mechanism for rotating the registering disks and a separate apparatus for inking them.

Fig. 3338.



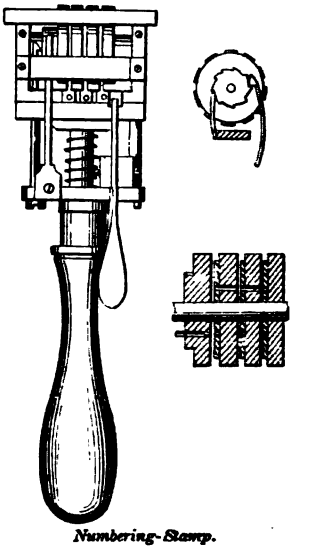
Paging-Machine.

In Hill's machine (Fig. 3338) the numbering-apparatus moves with the bed of a press operated in the ordinary manner, the inward movement of the bed-plate causing a spring-pawl to engage with a ratchet, and presenting the required number. A cross-head *H* is arranged to slide in vertical guides formed in the side-frames. In the longitudinal opening in the cross-head are fitted the stems of a number of hangers, each of which carries a numbering-wheel, and each wheel has a number of projecting types for imprinting the numerals. The desired movement is imparted to the numbering-wheels by rods, one of which is arranged to slide vertically in a bracket attached to each hanger. These rods have bent lower ends, which are made to engage with the teeth of a ratchet-wheel adjacent to the numbering-wheels, and thus impart the desired motion to the latter. See also PAGING-MACHINE.

Num'ber-ing-press. See NUMBERING-MACHINE.

Num'ber-ing-stamp. One for delivering consecutive numbers by successive impressions. A series of wheels have the series of figures from 0 to 9, and these have the usual connection by which pressure applied to an object sets in motion the unit-wheel. This is communicated to the next, carrying the tens, hundreds, and so on throughout the series. See NUMBERING-MACHINE.

Fig. 3339.



Numbering-Stamp.

Num'ber-print'-ing. The process whereby successive numbers are printed automatically on tickets, bank-notes, etc.

Various machines have been invented for this purpose, prominent among which are Bramah's, Shaw's, Edmonson's, and Trouillet's. See NUMBERING-MACHINE. Called a *numbering-machine* or *paging-machine.*

Nun-buoy. A buoy of a spindle shape, or formed of two cones joined at their bases.

Nurl'ing. The indentations or fluting on the edges of coins, the heads of temper and set screws, and similar objects. It is sometimes called *milling*, and in the mint is called *reeding.* The crenated edge on coin is intended to prevent clipping or filing the edges of the coin, which might otherwise be done to some extent without discovery, except by careful weighing.

Fig. 3340.

Nurling-Tool and Nurled Head.

Nurling applied to the edges of temper-screws is to make them more easy to grasp by the fingers and thumb. It is very common in surveying-instruments, on compasses, dividers, calipers, etc., and generally upon all instruments where a screw is to be loosened or tightened, in the ordinary uses of the instrument.

A *nurling-tool* has a roller whose periphery has a sunken groove, indented so as to form the counterpart of the bead which is to be nurled on the head of the temper-screw. It is held against the portion of the object to be nurled, while the said object is rotated in a lathe.

The nurling on the edge of a coin is made in the coining-press. By the great pressure (from 40 to 75 tons), the metal of the blank is forced outward into the indentations of the collar, which holds it while pressed between the two dies, forming the obverse and reverse respectively.

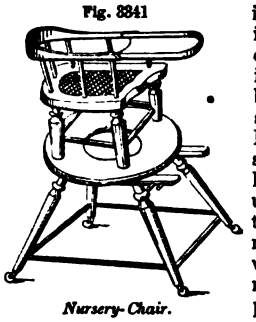
Nurl'ing-tool. (*Turning.*) A milling-tool. One for indenting the heads of temper and tangent screws, etc.

Nurs'er-y-chair. One for nursery uses; the example is convertible into a high-chair for table use, or with shelf in front for toys; or, when the upper part is removed, the lower forms a pan-chair.

Nurs'ing-bot'tle. One arranged to enable an

Digitized by Google

Fig. 3341

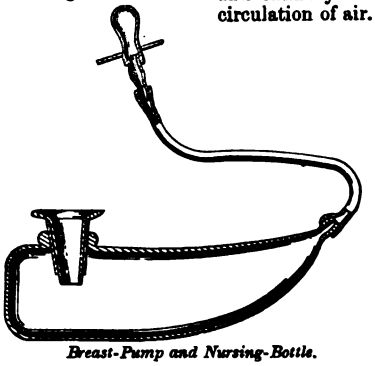


Nursery-Chair.

infant to draw milk from it by the natural action of sucking. Fig. 3342 is adapted to be used both as a breast-pump and a nursing-bottle. In Fig. 3343 the tubular stopper has a flexible leather tube extending up from the bottom of the bottle, so that it may nearly empty the bottle without drawing air. A nipple is attached to the projected end.

Nurs'ing-lamp. One for heating infants' food at night. The lamp-case is water-tight, and is submerged to heat the water in a bath. Pipes and chimneys afford a circulation of air.

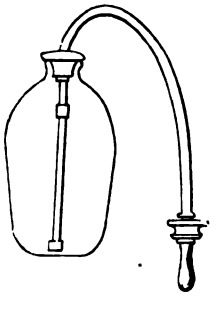
Fig. 3342.



Breast-Pump and Nursing-Bottle.

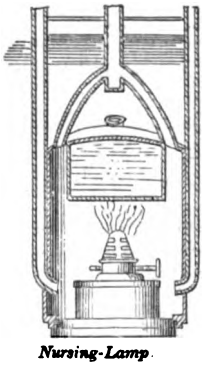
Nut. 1. (*Machinery.*) A piece of metal *a* tapped and adapted to be screwed on the end of a butt *b*.

Fig. 3343.



Nursing-Bottle.

Fig. 3344.



Nursing-Lamp.

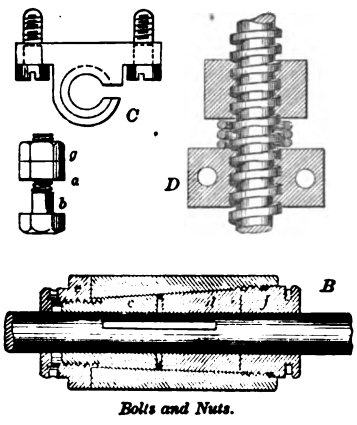
A second nut *g*, screwed down upon the first, is called a *jam-nut*, *check-nut*, *pinching-nut*, or *lock-nut*. (See NUT-LOCK.) A *nut-lock* is a device of any kind for fastening a nut; a *lock-nut* is a nut or bur which fastens another nut.

B shows a shaft and sleeve with two bushes *c d*, one drawn by a *drawing-nut e*, the other driven by a *forcing-nut f*.

C D are forms of elastic nuts. One has an opening which permits expansion, and the other screws down upon a spiral spring.

2. (*Vehicle.*) Axle-nuts are screwed on to the ends of the spindles or arms of carriage-axles, to

Fig. 3345.

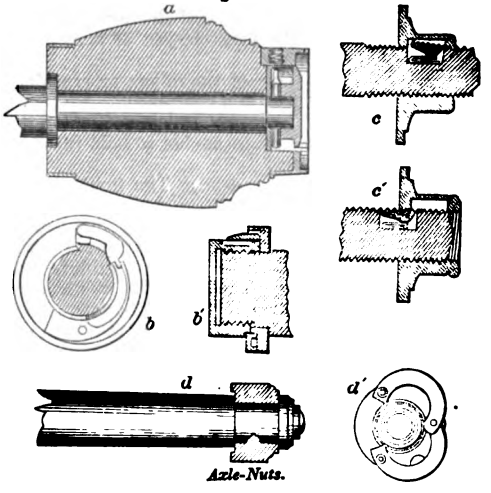


Bolts and Nuts.

hold the wheels on the spindles. The exercise of ingenuity in this line has been in devices to prevent the nuts from becoming unscrewed, and thus allowing the wheels to roll off. In the ordinary method, a closely fitting nut is screwed on the threaded end of the spindle, the threads on the near side of the carriage being left-hand threads, and those on the off side, right-hand threads, so that the ordinary motion of the wheels tends to roll the nuts on, and not off.

Sometimes the nut is fastened by a key of metal or leather, sometimes by a jam-nut. In the examples, *a* has a flanged cap instead of a screw-nut, and this is held by a transverse key slipped through a hole in the hub-band. *b b'* are views of an axle-nut

Fig. 3346.



Axle-Nuts.

which is secured on the axle by combining with it a spring friction-brake, which acts on the thread of the screw. The lever or arm of the brake extends beyond one of the faces of the nut, so that the brake may be withdrawn from the thread of the screw by the act of putting on the screw-wrench, to take off or put on the nut.

In *c c'*, when the nut is screwed up to its place, the lever-key is thrown into such position as to prevent the nut becoming unscrewed. To unscrew the nut, the lever-key is turned to a horizontal position

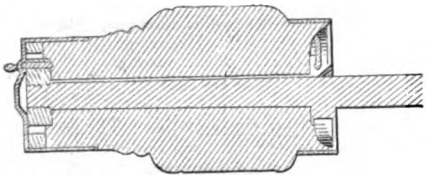
Digitized by Google

by entering a small iron pin through a hole and causing it to bear upon the key while the nut is started back. The two figures illustrate the respective positions of the lever-key.

In *d d'* the divided nut is clamped in a groove of the spindle, the shoulders of the groove being formed respectively of the enlarged, bearing portion of the spindle and of the outer boss. One portion of the nut may be hinged to the other, and the jaws opened to enable it to be placed in its seat; or the two pieces may be locked together in any convenient manner.

In Fig. 3347, a cap covers in the outer end of the hub, and is not removed for the purpose of taking

Fig. 3347.

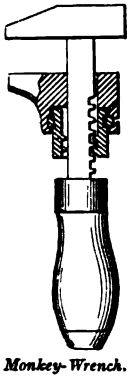


Young's Axle-Nut.

off the wheel. A pin is thrust in from the outside through a hole in the cap, and engages with a groove in the axle-nut, so as to lock the two together. The wheel being then rotated in the proper direction, the cap and nut revolve, and the latter is unscrewed from the end of the spindle, releasing the wheel without soiling the fingers by handling the nut.

Many devices to prevent nuts from becoming unscrewed are found in machinery subject to jar, and particularly in railroad-rail fastenings and fish-plates. See NUT-LOCK.

Fig. 3348



Monkey-Wrench.

3. The screwed sleeve which operates the movable jaw of a monkey-wrench.

4. One of the rollers or crushing-cylinders of a cider-mill.

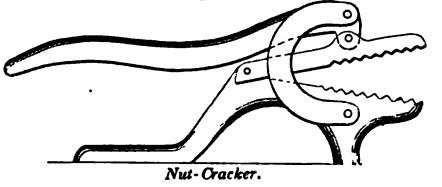
5. (*Nautical.*) A projection on the *shank* of an anchor to hold the *stock* in place.

6. (*Fire-arm.*) The tumbler of a gun-lock.

Nut-crack'er. An implement with jaws for cracking hard-shell nuts, such as hickory, walnut, Brazil, etc. The short arm of the lever is pivoted to the moving jaw, and it has fulcrum bearing in shackles which are pivoted to the fixed jaw and curved backward to give access to the jaws.

Nut-fas'ten-ing. See NUT-LOCK.

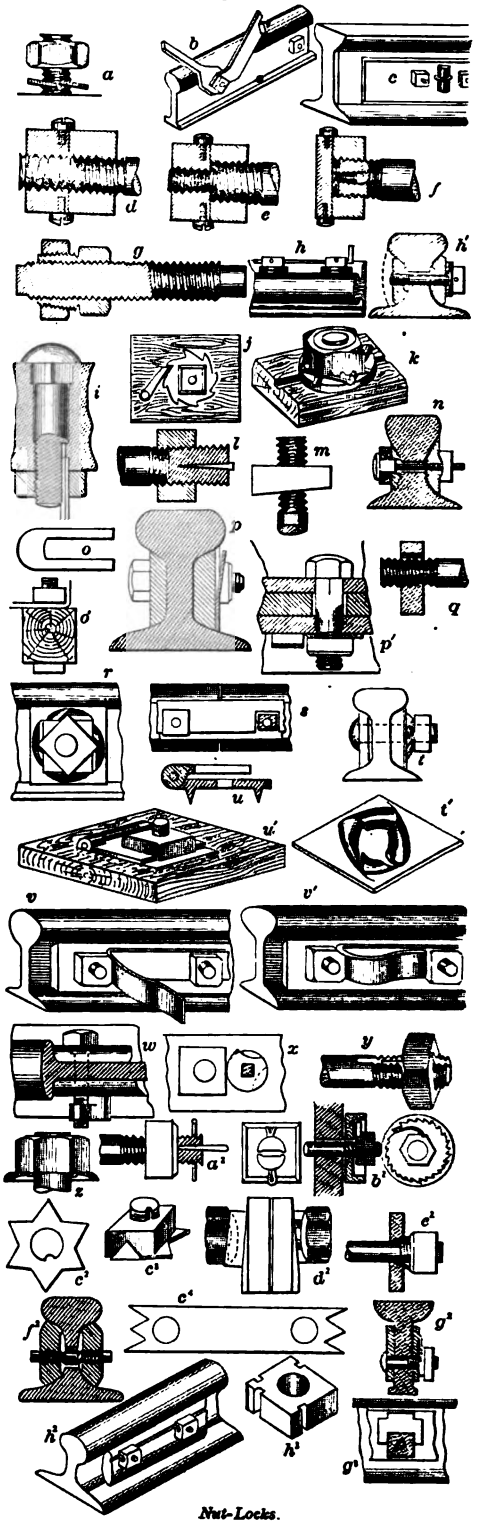
Fig. 3349.



Nut-Cracker.

Nut-lock. (*Machinery.*) A means for fastening a bolt-nut in place, preventing its becoming loose by the jarring or tremulous motion of the machinery. Such are used upon fish-bars of railways,

Fig. 3350.



Nut-Locks.

Digitized by Google

upon harvesters, and in many other places. In railways especially there has been a great demand to hold the nuts from being loosened by the shocks of the passing trains.

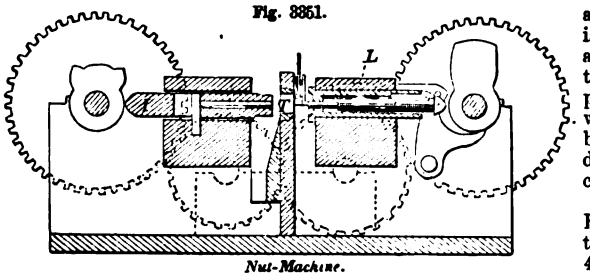
Fig. 3350 shows a number of these devices, some of which are American, others foreign. They require but little description, being simple and readily represented by drawing.

a has a washer cut obliquely so as to present cutting edges which sink into the nut and bar respectively.
b has a plate which fits between the two nuts of a fish-bar.
c has a plate which fits over the nuts, and is held by a staple and key.
d e are forms of jam-nuts, right and left handed, the outer one being of smaller diameter and allowing the lower nut to be slipped over it. They also have exterior set-screws.
In *f* the left-hand screw is interior, and its head jams against the face of the lower nut.
g has a conical screw portion, having longitudinal slits which allow it to be pinched down upon the bolt-screw by the outer nut.
h h' has a through-pin which transfixes the nuts.
i has a feather which lies in a longitudinal groove in the bolt and a spline-way in the nut.
j has a ratchet-washer and a click; the nut is partially imbedded in the washer.
k has pins which enter opposite grooves in the contacting faces of the washer and nut.
l has a split bolt and spreading wedge.
m has an unequal-sided washer, which causes one side to jam against the object and partially imbed itself.
n has a concave-faced nut which slips on to a seat on the washer or fish-bar.
o o' show a bifurcated washer, the legs of which are bent up against the nut.
p p' has a split washer, one part of which springs up against the side of the nut.
q is a gravitating nut, being heavier on one side.
r has a washer with wings which spring up against the sides of the nut.
s has a notched plate which slips over recesses in the nuts.
t t' has spring wings on the washer to hold the nut.
u u' are two views of a washer with a hinged section which holds the nut.
v v' show forms of flexible washer-strips.
w has a nut with a gravitating extension-piece.
x has a cam which jams against the nut.
y is a bolt with groove for spline, and a corresponding groove on each side of the nut.
z is a nut which jams down upon a yielding washer.
a^2 shows two views of one having a split bolt, and a wedge held by a key.
b^2 shows two views of a nut with internal ratchet and a spring-click on the bolt.
c^2 c^3 c^4 are the Noblet washer, which has a portion to turn up against the nut, and a farther portion which may be turned down against the object, if desired.
d^2 is the Nicholson (1852) bolt with a semi-spherical bearing surface, and nut made to suit.
e^2 is Adam's wedge-formed washer (1856).
f^2 has a right and left double-ended screw-bolt.
g^2 g^3 are two views of a form in which a washer beneath the nut has a lip which projects into a slot in the fish-bar.
h^2 has a long washer-slip with a piece turned up to form a key.
h^3 shows the grooved nut.

Nut-ma-chine'. A machine for forming nuts from the solid bar by cutting or swaging.

In Fig. 3351, the heated bar is placed against a gage, the slide *I* is forced forward and the blank is cut from the bar; the blank is forced into the die *T*, to which the rounded header has been advanced by the movement of the slide *L*. The advance of the punch perforates the nut and forces the piece into the hollow left by the recession of the slide *I*, whose second forward movement discharges the nut.

Fig. 3351.

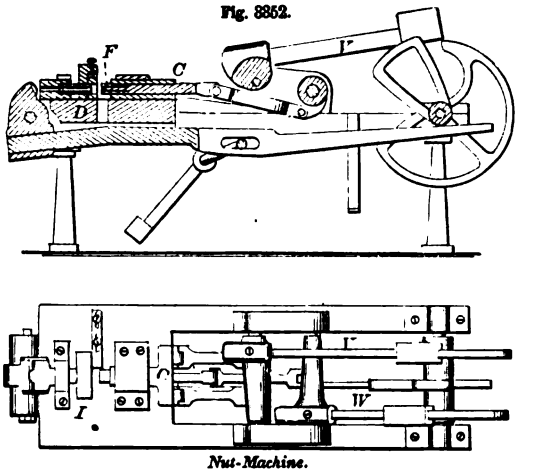


Nut-Machine.

In Fig. 3352, the blank is cut from the heated rod by the punch *D*. The ram *C* moves forward, carrying the holing-punch *F*, which is advanced, making the hole in the nut, after which they recede from each other, allowing the nut to be pushed out by the follower *I*. The swaging and holding punches are actuated by toggle-joint connection with the levers *V W*, producing a hammering action rather than a positive limited pressure.

In Fig. 3353, the sliding carriage *B* carries the cutter *H* (the cutting edge of which is beveled to cause any desired chamfer), and the borer *J*. The rod *E*, of hexagonal or other shape adapted to the kind of nut required, passes through similarly shaped rings, which prevent it from slipping during

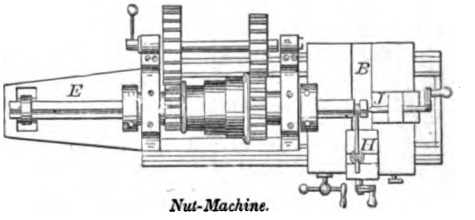
Fig. 3352.



Nut-Machine.

rotation. When 6 or 8 blanks have been cut by advancing the carriage, this is drawn back, the bar

Fig. 3353.



Nut-Machine.

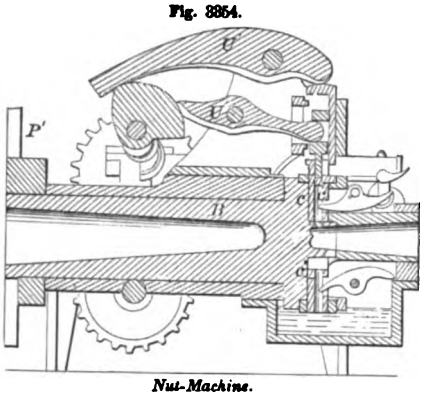
is fed forward, and a new series of turning and drilling operations commences.

In the machine (Fig. 3354) the dies are arranged around the bed-roller *B*, which is intermittingly moved by the curved arms *P P'*, etc., so as to bring each die at the proper moment under a corresponding punch, actuated by the levers *U U'*, which cut out the nuts from the heated bar. They are then delivered from the die by plungers *c*. Punches, operated by cams, perforate the nut.

Nut'meg-grat'er. The largest four Banda islands are exclusively devoted to the growth of nutmegs, producing yearly 400,000 pounds of nutmegs and 130,000

Digitized by Google

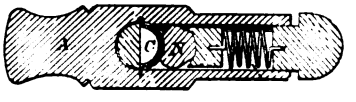
Fig. 3354.



Nut-Machine.

pounds of mace. The nutmeg-tree grows 30 feet high, and resembles the orange, the pale yellow flowers and fruit, in various stages of maturity, be-

Fig. 3355.



Nutmeg-Grater.

ing all together on the tree. The fruit is at first of a light green color, becoming yellow when ripe, with a longitudinal form. The external covering, at first thick and fleshy, and filled with acrid astringent juice, subsequently becomes dry and separates into two valves, disclosing the scarlet network known as mace. Within the latter is a thin brown shell containing the nutmeg. The fruit is gathered and divested of its outer coverings, the mace being carefully collected and dried in the sun. The nuts are dried in the sun, or in an oven, and smoked until the kernel rattles. The shells are then broken open and the kernels, having been steeped in lime-water, are packed in chests for exportation. The tree is produced from the seed, flowers in the ninth year, and continues bearing fruit and flowers all the year round for seventy years.

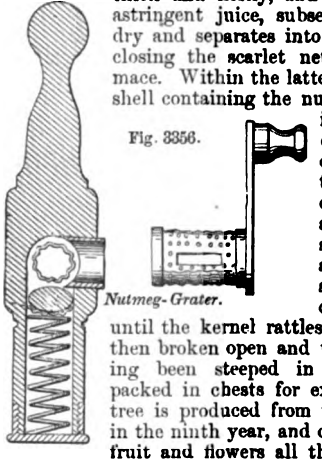


Fig. 3356.

Nutmeg-Grater.

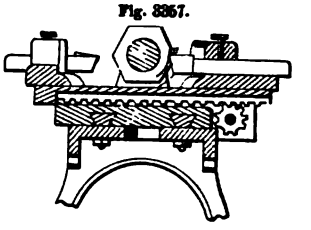
Besides the old-fashioned grater, in which the nut and the knuckles are impartially rasped, may be mentioned two other kinds. In Fig. 3355, the nutmeg *N* in the tube of the stock *A* is pressed by the spring against the grater *C*, which is reciprocated in the transverse opening.

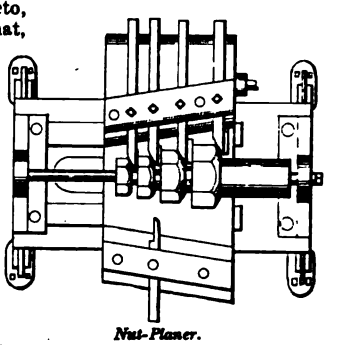
In Fig. 3356, the grater revolves in a stock, and the nutmeg is pressed against it by a spiral spring which bears against a removable cap, covering the opening by which it and the spice are introduced.

Nut-plan'er. A series of nuts of different sizes are screwed to the mandrel, and one side of the latter is a sliding tool-rest, to which are screwed a series of tools, having each two cutting edges, by which a number of nuts can be simultaneously faced and beveled.

Nut-roast'er. A rotary cylinder is confined in a hot-air case, and provided with gas-burners. A warming-apparatus, to which the tube that supplies gas to the roasting-apparatus is connected for supplying heat thereto, is so arranged that, after the nuts have been roasted and placed in the said warming-apparatus, the flow to the roasting-burner may be stopped, while that to the warming-apparatus continues.

Fig. 3357.

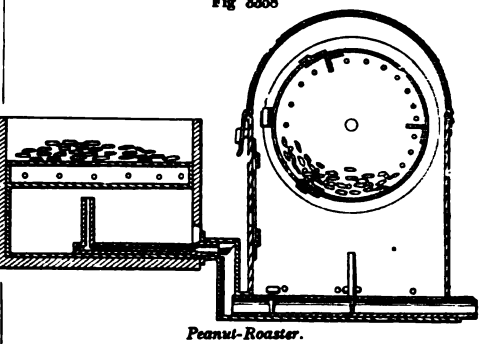




Nut-Planer.

Nut-shap'ing Ma-chine'. A machine for the purpose of shaping the external faces of hexagonal nuts. Six horizontal revolving cutters are arranged radially at the same level, and

Fig 3358



Peanut-Roaster.

driven by a single bevel-wheel gearing into the six bevel-pinions that carry the cutter-spindles. The cutters are so fixed in their spindles that when the cutting edges of one tool are horizontal, those of the adjoining one are vertical, and they consequently miss one another in revolving, and can thus operate on work the faces of which are narrower than the breadth of the cutters; by this means the contiguous faces of hexagonal nuts are all shaped simultaneously by the revolving cutters. The nuts to be shaped are threaded upon a vertical center mandrel, to which a vertical feed-motion is given, traversing the nuts upward or downward in the middle of the revolving cutters; and the shaping of the six faces of the whole row of nuts on the mandrel is completed in a single traverse of the machine.

Nut-tap'ping Ma-chine'. For cutting screw-threads in punched nut-blanks. A machine resembling a drill-bench, with taps mounted on the ends of its mandrels.

Nut-wrench. A spanner for rotating nuts. See MONKEY-WRENCH, and list under WRENCH.

Digitized by Google

O.

Oak'um. (Anglo-Saxon, *acumba.*) 1. The coarse portion separated from *strick* (strike: A.-S., *stricau*) of flax or hemp in hackling.

2. Untwisted rope; used for *calking* the seams of a ship's plank, being forced thereinto by chisel and mallet. A first-rate ship of war requires 67,000 pounds of oakum to close the seams.

Oar. 1. (*Nautical.*) An instrument for rowing. A long paddle which rests in tholes on the gunwale in rowing.

A long oar, used occasionally to assist a vessel in a calm, is a *sweep*, and is operated by two or more men.

Small oars are *sculls;* one rower wielding a pair, sitting midlength of the *thwart. Sculling* a boat is performed by an oar shipped in a half-round hole at the stern, the oar being moved with a twisting action from side to side.

A *rigged oar* is one in which the oar is pivoted to the gunwale and moved by a rod, or otherwise by a rower sitting abaft it, so that he may face forward.

The *blade* of the oar, also known as the *wash*, is the broad flat part which is dipped into the water in rowing. The *blade* was formerly known as the *pala*, which survives in the term *peel*, yet applied to it. The term *pala* meant a spade; the older forms of paddles might be used for digging.

The *loom* of the oar is the shaft, beginning at the blade, and terminating in the *handle*, which is of rather smaller diameter than the *loom*, in order to afford a good hand-hold to the rower.

The oar when in use rests in *rowlocks* in the gunwale of the boat or between *thole-pins*, which are round pegs, inserted in holes bored in the gunwale.

To *boat* oars means to cease rowing and lay the oars in the boat.

To *feather* oars is to turn the blades in a horizontal position on lifting them from the water at the end of each stroke, to afford as little resistance as possible to the water in withdrawing, and to the air.

To *ship* oars is to place them in the rowlocks or between the thole-pins, ready for use.

An oar is frequently used for steering: in which case it is sometimes an ordinary oar shipped in a swiveled fork at the stern, as in whale-boats; or it may be a broad paddle attached to a long arm, working on a swivel near its center, or similar device, as is often the case in keel-boats, scows, etc.

To *lie on the oars* is to raise them from the water and hold them horizontally.

To *muffle the oars* is to put sheepskins in the rowlocks to prevent any sound in rowing.

To *toss the oars* is to raise them vertically, resting on the handles. It is a form of salute.

To *unship the oars* is to take them out of the rowlocks.

Single-banked is when the oars are rowed, one to each thwart, starboard and port sides alternately.

Double-banked is when two opposite oars are pulled by two rowers seated on the same thwart, or by two men at each oar.

The term *bank*, as applied to galleys, meant a tier of oars, as *double-banked, single-banked*, etc.

Says Pliny: "The Copæ invented the oar, and the Platæans gave it its broad blade." We suppose he means a fair distinction between the oar which rests in tholes and the paddle which is handled without receiving a fulcrum support on the gunwale.

The great ship of Ptolemy Philopator had forty ranks of rowers; the oars of the longest row were 38 cubits in length (say, 57 feet). These were loaded with lead on the part inside of the rowlocks, so as to evenly balance.

The scarcity of timber in Eastern lands had a great deal to do with the importance and peace of nations thereabouts. The possession of Lebanon and Bashan was not one of the least of the points in dispute between the two branches of the Macedonian Empire represented by the Seleucidæ and the Ptolemies.

These struggles fill up the time between the death of Alexander and the absorption of the country by the Romans, and form the history which was so remarkably portrayed in prophecy by Daniel several hundred years before. See the 11th chapter of Daniel.

While the fir-trees of Senir furnished the planks, and the cedars of Lebanon the masts, the oaks of Bashan contributed the oars of the famous galleys of Phœnicia. Being the great carriers of that day, and having direct dealings with Britain, India, Greece, Spain, Africa, and many ports whose names remain but whose localities are difficult to determine, these "princes of the sea" and artificers upon the land were in demand wherever an extra amount of intelligence, taste, skill, and daring was required. Two lands at least contributed the timber of their vessels, another the cordage, another the sails, another the oars, others the ivory, ebony, and sandalwood for adornment; Palestine contributed its iron.

Copper from the same land and the Caucasus was mingled with the tin from the far-off Cassiterides, the first contribution of Britain to the common stock of the world's merchandise, and which had the honor of forming with copper the alloy which made the brazen (*bronze*) laver and furniture of Solomon's Temple.

Though littoral Tyre was destroyed by Nebuchadnezzar, and insular Tyre by "young Ammon," the "rough he-goat, the king of Grecia," yet she survived in her colonies until the Roman maelstrom drew them all into its vortex and swamped the distinctiveness of many nations.

The best picture of the time is that given in Ezekiel xxvii. (which see).

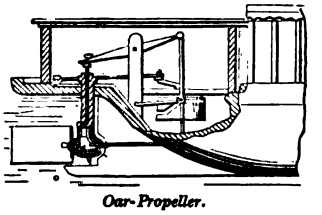
Machines are made for dressing, planing, riving, and splitting oars, but do not differ so specially from machines for getting out and dressing stuff for other purposes as to require elaborate description here.

2. (*Brewing.*) A blade or paddle with which mash is stirred in the tun.

Oar-lock. (*Nautical.*) A means of pivoting an oar on the gunwale. A ROWLOCK (which see).

Oar-pro-pel'ler. 1. A device to imitate by machinery the action of sculling. Two submerged blades at the stern are attached to an oscillating, vertical shaft and brought broadside to the water and feathered, alternately, so as to make an effective and a return stroke. The horizontal shaft

Fig 3359.



Oar-Propeller.

Digitized by Google

of the blades receives an oscillation in a vertical plane, while the sleeve to which its hub is secured is oscillated in a horizontal plane, so that it receives a double oscillation, once around its own axis and also around the axis of the vertical shaft.

Fig. 3360.

Oar-Swivel.

In another form, the blades are oscillated with their rock-frame, and are feathered, so as to move forward edgeways and move backward flatways to propel the boat.

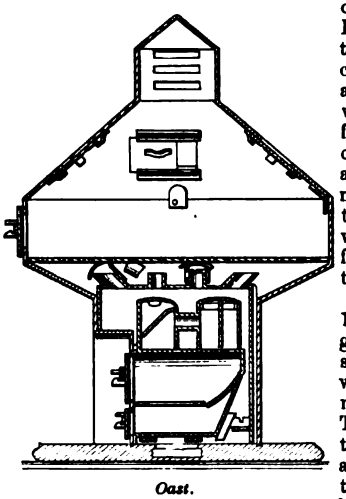
A canal-boat, propelled by oars, was used on the Sankey Canal, Lancashire, England, in 1797. The oars made 18 strokes per minute, and were operated by a steam-engine.

Oar-swiv'el. A pivotal device for an oar on the gunwale. A *rowlock*. In the example, the oar is hung in gimbals, which allow it vibration in any plane, and it has besides a capacity for rotation on its own longitudinal axis in feathering. See ROWLOCK.

Oast. A hop-drying kiln.

The kiln has an upward draft, the floor being perforated and the hops lying upon hair-cloth. In the example, the furnace is covered by an arch of brickwork or metal, forming an air-chamber around the furnace from which the air is conveyed to the foraminous bottom of the kiln.

Fig. 3361.



Oast.

Ob'e-lisk. 1. A quadrangular, slender stone shaft, with a pyramidal apex. The width of the base is usually about one tenth of the hight, and the pyramidal apex has about one tenth of the whole length. It is Egyptian in its conception and execution. Obelisks were erected in pairs, and are yet numerous on the ancient sites, and no doubt many prostrate ones are buried in the soil of Egypt, which has risen from the deposit of the Nile 9 feet in 1,700 years at Elephantine, and 7 feet at Thebes. The deposit of mud at Thebes, therefore, since Amunoph I., would be about 17 feet.

There are about a dozen Egyptian obelisks erected in Rome. The largest is that from Heliopolis. It is of granite, and now stands before the north portico of the Church of St. John Lateran, where it was erected in 1588. Its whole hight is about 149 feet; without the base, 105 feet. It was removed to Alexandria by Constantine, and to Rome by his son Constantius, and placed in the Circus Maximus. It was overthrown, broken into three pieces, and a piece was removed from its base before re-erecting. It weighs about 985,600 pounds. Its partner yet stands at Heliopolis. It is marked with the name of Osirtasen I., about 2100 B. C. Roman obelisks were also imported by Augustus and Caligula.

Other obelisks are found at Constantinople, Paris, Arles, Florence, etc.

The Egyptian obelisks are usually of granite, but there are two small ones in the British Museum made of basalt, and one at Philæ of sandstone. The date of the Flaminian obelisk, which is covered with hieroglyphics, is supposed to be about 1600 B. C.

The obelisk in Paris, erected in 1833, was brought from Luxor. It is 76 feet in hight. Of the needles of Cleopatra, so called, one is standing, 63 feet in hight, and the other is lying upon the ground.

"The mode of raising an obelisk seems to have been by tilting it from an inclined plane into a pit, at the bottom of which the pedestal was placed to receive it. A roller of wood was fastened at each side to the end of the obelisk, which enabled it to run down the wall opposite to the inclined plane to its proper position." — WILKINSON.

For a full description of the mode of moving and re-erecting an Egyptian obelisk, see the quarto "L'Obélisque de Luxor, Histoire de sa Translation à Paris," Paris, 1839. See also Cresy's "Cyclopedia," ed. of 1865, pp. 38, 40; also pp. 1013–17.

2. A reference-mark in printing (†); also called a dagger.

Ob'ject-find'er. (*Optics.*) A means of registering the position of a microscopic object in a slide, so that it may be readily found in future.

Maltwood's finder is a glass slide 3 × 1¼ inches with a scale occupying 1 square inch ruled into 2,500 squares. See "Beck on the Microscope," p. 67.

Ob'ject-glass. (*Optics.*) The glass at that end of a telescope or microscope which is presented toward the object. The *objective*. By it an image of the object is formed, to be viewed by the eye-glass. In good instruments of either kind the object-glass is achromatic and composed of several lenses, one being of flint-glass and the other or others of crown-glass. See ACHROMATIC-LENS; LENS; TELESCOPE; EYE-GLASS; FIELD-GLASS.

Ob-ject'ive. (*Optics.*) That lens or combination of lenses in a microscope or telescope which brings the image of an object to a focus in order to be viewed through the eye-piece. The object-glass. Though acromatic lenses had been applied to telescopes by Dollond near the middle of the eighteenth century, yet in 1821, according to Biot, opticians regarded the construction of a good achromatic microscope as an impossibility.

In 1827 Professor Amici of Modena exhibited in England and Paris a horizontal microscope whose object-glass, of large aperture, was composed of three superimposed lenses. A microscope constructed by Chevalier, on Amici's plan, was awarded a silver medal.

The theory of the subject was about this time investigated by Sir John Herschel, Professor Airy, and others, and, acting on their theoretical views, Mr. Joseph Jackson Lister succeeded in effecting one of the greatest improvements in the manufacture of achromatic object-glasses by uniting a plano-convex flint lens with a convex lens by means of Canada balsam.

This diminishes by nearly one half the loss of light occasioned by reflection where the surfaces unite, and prevents the dampness or the formation of mold at the junction.

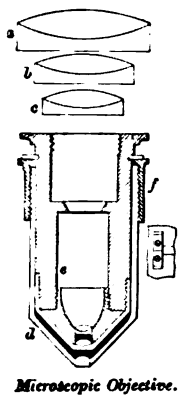
Mr. Ross, who subsequently devoted much time to the improvement of objectives, employs three lenses of this kind in order to correct the chromatic and spherical aberrations corresponding to varying

Digitized by Google

distances of the object, when it has to be viewed through an interposed plate of glass.

This is effected — supposing the posterior and middle combinations *a b* to have together an excess of negative aberration — by causing the anterior combination *c* to have an excess of positive aberration, and varying its distance from the other pairs.

Fig. 3362.



Microscopic Objective.

For this purpose the anterior lens is set in the end of a tube *d* (as shown in the lower portion of the figure), which slides on a cylinder *e*, containing the remainder of the combination, and is caused to approach or recede therefrom by turning the screwed ring *f* or by simply sliding the tube on the interior cylinder, afterward clamping it.

An aperture is made in the tube *d*, through which is seen a mark engraved on the cylinder. A longer and shorter mark are engraved on the tube; and by bringing the former into coincidence with the mark on the cylinder the adjustment is perfected for an uncovered object. When the shorter mark is made to coincide with the mark on the cylinder, the proper adjustment is attained for correcting the aberration occasioned by glass $\frac{1}{100}$ of an inch in thickness.

Ob'ject-staff. (*Surveying.*) A staff the same hight as the level, forming a sight to be viewed from thence in determining levels.

A leveling staff consists of a graduated strip sliding in the dovetail groove of an upright bar, and provided with a cross-bar to whose crucial point the eye of the leveler is directed. The said bar is raised or lowered until it meets the level, and the hight is read on the staff. The sliding is for purposes of extension when the level is above the top of the main bar.

Ob-lique' Arch. One which conducts a road or railroad across a river, canal, etc., in an oblique direction; also called a *skew-arch*.

O'bo-e. (*Music.*) Or *hautboy*. A double-reed instrument with a compass of two octaves and a sixth, and written on the G clef. It has three pieces besides the reed-piece.

b. A reed-pipe stop of an organ, tuned in unison with *open-diapason*, and depending for the peculiar quality of its tone upon the shape of the tube through which the sound of the reed is transmitted. See STOP.

Ob-serv'a-to-ry. 1. A building provided with instruments for astronomical observations. See ASTRONOMICAL INSTRUMENTS; ARMILLARY-SPHERE, etc. See list under OPTICAL INSTRUMENTS.

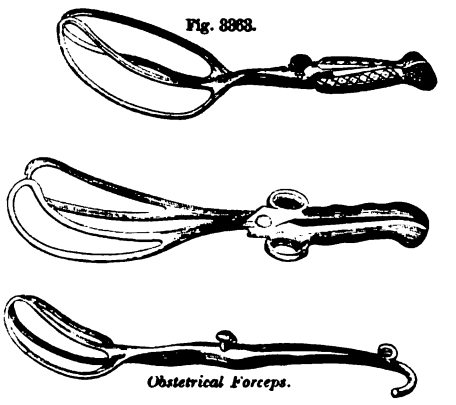
2. A chamber of observation at such an altitude as to look over adjacent objects and afford an extensive view. Used as a lookout-station for the fire-alarm service, for signaling, for meteorological observations, etc.

The iron observatory on the roof of the Equitable Life Insurance Company, on Broadway, New York, is 22 feet high above the roof of the building, which is 130 feet above the sidewalk. The probabilities of the weather are indicated by balls 12 feet in diameter, displayed upon two signal-staffs and visible from various points on Long Island Sound, Sandy Hook, and the inland waters of the Hudson and Harlem rivers. In the building is a large map, displaying the territory throughout which the service has its stations, reaching from Mexico to Canada, and from the Atlantic to the Pacific coast. The state of the weather is indicated by dials at each of these stations on the map, from which reports are received every five hours.

Ob-stet'ri-cal Chair. One capable of affording convenient position for the delivery of the child and access of the midwife.

Ob-stet'ri-cal For'ceps. (*Surgical.*) An accoucheur's instrument for grasping the head of the child and facilitating delivery. They are of varied shapes and construction, and have specific means,

Fig. 3363.



Obstetrical Forceps.

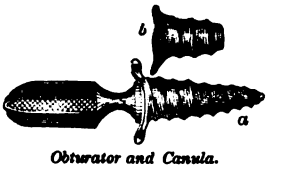
such as rings or hooks, to assist the hand when force is applied. The instrument was described by Butler in 1732.

Ob-stet'ri-cal In'stru-ments. (*Surgical.*) For assisting delivery, measuring the pelvic opening, etc. Among them may be enumerated the *cephalotribe, crochet, forceps, obstetrical supporter, pelvimeter, perforator, placenta-forceps*, and *hook*. Herophilus of Alexandria, of the school of Ptolemy, wrote on obstetrics.

Ob-stet'ri-cal Sup-port'er. One having braces around the hips and knees, and affording holds for the hands, to assist the muscular exertions of the mother during parturition.

Ob'tu-ra'tor. (*Surgical.*) An instrument for distending an opening, as in the example, which shows a pointed screw-shaped appliance, used in cases of lithotomy. The instrument shown at *a* is thrust through the portion *b*, and together with it is driven, by pressure and rotation, through the opening made by the gorget, distending it. The *obturator a* is then withdrawn by backward rotation, leaving the *cannula b* in situ, to form a channel through which the *lithontriptor* or *lithoclast* is introduced to crush the stone.

Fig. 3364.



Obturator and Canula.

Ob'verse. The face of a coin or medal. The other side is the *reverse*.

An *obverse* tool has the smaller end toward the haft or stock.

Oc'ta-chord. (*Music.*) A musical instrument having 8 strings.

Oc'tant. (*Optics.*) An instrument for measuring angles, resembling a quadrant or sextant in principle, but having an arc of 45°, the eighth part of a circle. See SEXTANT.

Oc'tave Flute. (*Music.*) A flute having a pitch

Digitized by Google

an octave higher than the ordinary flute. A *piccolo*. See MUSICAL INSTRUMENTS, Fig. 3263.

Oc-ta'vo. A sheet printed with 8 pages on each side. 8vo.

Oc'to-bass. (*Music.*) An instrument of the viol family, the low octave of the violoncello. It has three strings tuned in fifth and fourth. It has movable keys to press the strings upon frets of the neck. The keys are moved by lèvers governed by the left hand, and by pedal keys on which the foot of the player acts. Its compass is one octave and a fifth.

Oc-to-dec'i-mo. A sheet printed to make 18 pages on a side. 18mo.

Oc'to-style. (*Architecture.*) Having eight pillars on a front.

Oc'u-lar; Oc'u-laire. The eye-piece of a telescope or microscope.

Odd-side. (*Founding.*) When many castings are required from one pattern, or from a number of patterns, molded in the same flask, the *false-part* is prepared with care in an odd-flask, and is preserved indefinitely. By the use of a good *odd-part*, much time is saved in making the parting.

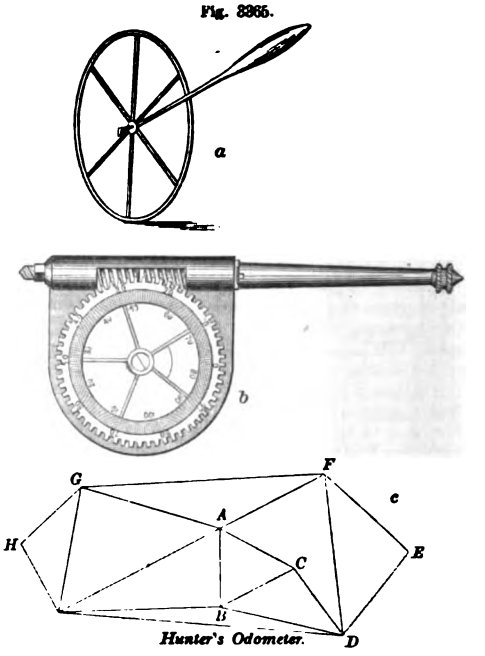
O-dom'e-ter. "The machine for *measuring distances when traveling*," Vitruvius says, "was discovered by the ancients and is yet found very useful." (50 B. C.) When adapted for a chariot or traveling carriage, the wheels were made of such a diameter that every revolution would advance the vehicle 12½ feet. Thus 400 revolutions passed over 5,000 feet, or a Roman mile. The diameter of the wheels was therefore nearly 4 feet. A drum-wheel was fixed to the inner side of the hub of the wheel, and had one small projecting tooth, which, at each revolution, turned one tooth of a cog-wheel journaled in a box above and having 400 teeth. This cog-wheel had a single projecting tooth which acted on a third wheel which had holes equal in number to the number of miles in an ordinary day's journey.

In each hole of the third wheel was placed a small ball, and these were brought consecutively to an opening in the case through which they dropped into a metallic vase; indicating audibly the transit of one mile at each sound of the ball. By the numerical proportion of the gearing, a ball was dropped at every 400th revolution of the carriage-wheel to whose hub the first drum-wheel was attached. At the end of the journey the number of balls indicated the number of miles traveled.

Vitruvius, in his tenth book, describes a machine of this kind for a carriage, and which, in his opinion, would answer for a ship. We are told by Capitolinus, in his life of the Emperor Pertinax, that among the effects sold, of the Emperor Commodus, there were carriages which "measured the road and pointed out the hours" (et alia iter metientia, horasque monstrantia).

Hunter's odometer *a*, the working parts shown enlarged at *b*, has a light wheel, 6 feet in circumference. This is driven by a handle grasped by the pedestrian. On the axis of the wheel is a worm, which engages two cog-wheels which have 100 and 101 teeth respectively. 100 revolutions of the axis will turn each wheel 100 teeth, so that the zeros of the wheels will be one degree of the scale apart. Another 100 revolutions of the wheel will make their zeros 2 divisions distant, and so on. In the cut the zeros are 78 divisions apart, and the upper index points to 26 of the scale. As each revolution of the wheel is 2 yards, and the revolution of the first cog-wheel is $2 \times 100 = 200$, each degree of variation is equal to 200 yards. $78 \times 200 + [26 \times 2] = 15{,}652$ yards.

Fig. 3365.



Hunter's Odometer.

The range of the instrument is when the zero of the second cog-wheel has again reached the zero of the first, which shows $101 \times 100 = 10{,}100$ revolutions of the axis, which being 6 feet, the range is found to be $10{,}100 \times 6 = 60{,}600$ feet = nearly 11½ miles.

The odometer is employed in mapping districts of country, filling details of roads and lanes in triangulations. One form used by the United States Coast Survey is a wheel 2 feet 7½ inches in diameter, 8 feet 3 inches in circumference, traversing one rod in 2 revolutions. The index in the box points to miles and rods traversed.

Odometers are sometimes used in hacks and carriages for casual hire, to determine the distance.

Fernel, physician to Catharine de Medici, Queen of France, measured with an instrument of this kind, in 1550, a degree of the meridian between Paris and Amiens, and found it to be 303 toises less than Picard afterward found it to be. It is supposed that the revolutions of the wheel were noted by striking on a bell.

The measurement of a degree of latitude has been made and recorded not less than fourteen times in the last 1,000 years. Its length varies in different countries, as the facts show and theory had supposed.

Eratosthenes, B. C. 276, attempted the measurement of the size of the earth, by ascertaining the distance between Alexandria and Syene, the differences of latitude between which places he had found to be $\frac{1}{50}$ of the earth's circumference.

Some previous measurements are mentioned under ARMIL (which see). Hipparchus of Nicæea in Bithynia, 162 B. C., laid down a map by the determination of the latitude and longitude of places. A degree was measured on the shores of the Red Sea by the Khalif al Maimoun, the son of Haroun al Raschid, about A. D. 820.

The exact determination of the length of a degree was considered of so much importance that, in 1735, the Academy of Sciences of Paris dispatched two commissions, one to Peru, the other to Lapland.

Digitized by Google

The latter party accomplished their mission and returned in 16 months; the former party, after contending with great hardships for 10 years, accomplished their mission, as Frenchmen in pursuit of an idea will do, if anybody can.

Since the work of the French Academicians, measurements have been taken in India, France, England, Hanover, Lithuania, and Sweden. One curious discovery resulted, as stated by Sir John Herschel: —

"The earth is not exactly an ellipsoid of revolution. The equator itself is slightly elliptic, the longer and shorter diameters being respectively 41,852,864 and 41,843,096 feet. The ellipticity of the equatorial circumference is therefore $\frac{1}{1743}$, and the excess of its longer over its shorter diameter 2 miles."

The polar axis is 41,707,796 feet in length.

It is many years since better devices superseded the old plan of measuring the surface, as adopted by Fernel in 1550. Picard's more correct estimate was made in the next century, but it is not recorded whether he made it by a direct measurement by rods and chains, or by a measured base-line and subsequent triangulation.

The base-line on which the Ordnance Survey, the triangulation of Britain, is founded, is 5.2 miles nearly. It is said that the greatest *possible* error in the length of this line is 2 inches. See SURVEYORS'-CHAIN.

The diagram *c*, Fig. 3365, will explain.

"A level piece of ground is selected near the meridional arc proposed to be measured. On this a straight line *A B* is traced, and its length accurately found by the application of rods of metal, wood, or glass. The ground adjoining the arc to be measured is then divided into triangles by means of signals *C, D, E, F, G, H, K*, erected at convenient distances or on remarkable points of the country; and the angles which the signals make with each other determined by a theodolite or similar instrument. The sides *A C, B C*, are then deduced from the measured base *A B*, and thence successively the sides of the other triangles. In this manner the whole distance between the stations which form the terminal points of the arc is determined by a series of trigonometrical calculations. The reductions for the differences in the levels of the respective stations must next be applied, and also for their altitude above the level of the sea."— BRANDE.

The following table shows the length of a degree of latitude at every tenth degree: —

Latitude.	Length of degree in English feet.	Latitude.	Length of degree in English feet.
0	362,734	50	364,862
10	362,843	60	365,454
20	363,158	70	365,937
30	363,641	80	336,252
40	364,233	90	366,331

The length of the degrees of longitude at every tenth degree is as follows: —

Latitude.	Length of degree of longitude in English feet	Latitude.	Length of degree of longitude in English feet.
0	335,152	50	235,171
10	329,640	60	183,029
20	343,263	70	125,254
30	316,498	80	63,612
40	280,106	90	0

Odometers were possessed by Augustus, the Elector of Saxony, A. D. 1553–86, and the Emperor Rodolphus II. 1576–1612. In the eighteenth century they became common, and descriptions are found in scientific reports and works of that date.

Hohlfield, born at Hennerndorf, in Saxony, in 1711, seems to have much improved the instrument.

A new French instrument, termed a "compteur mécanique," or calculating-machine, not only reckons the distance traversed, but indicates as well the exact sum of money due to the driver. Two dials are fixed on the back of the driving-seat; one contains a clock, while on the other the distance traveled is indicated by a hand acted on by the wheels; it is entirely beyond the control either of cabby or his "fare." The apparatus is put in and out of gear by the lowering and raising of a lever bearing the word "libre," which is only visible when the cab is empty, and the "compteur" consequently unemployed. There is no danger of the driver omitting to lower this lever as soon as he is hired, it being evidently his interest to have the greatest possible distance paid for; while, on the other hand, it would be useless for him to try to make a fictitious fare by driving about with his "compteur" in motion, for a card in the interior of the machine registers the distance traversed during the day, and the money to be accounted for to the cab-owner. The great difficulty has hitherto been to find a means of marking the time spent in visits, shopping, blocks in the streets, etc., when the wheels and the tell-tale are necessarily at a standstill. M. Bruet, the inventor of the new register, has now overcome this difficulty by a contrivance, by means of which, as soon as the wheels cease to act on the indicator, the clock which forms part of the machine keeps the tell-tale hand moving at a rate which credits the driver with eight kilometers (about five miles) an hour, or two francs, according to the Parisian tariff.

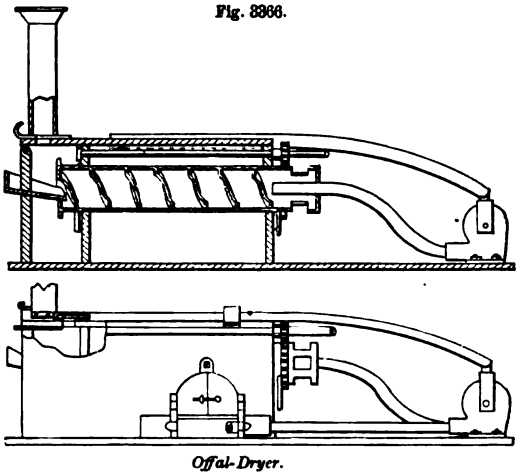
O-don'ta-gra. A form of dental forceps.

O-don'to-graph. (*Gearing.*) An instrument for marking or laying off the teeth of gear-wheels; invented by Professor Willis. It consists of a graduated card or thin board, having one edge beveled at an angle of 75°. This is applied to the radii terminating at the centers of the interspaces between the teeth and the centers from which the curves forming their flanks and faces are laid off from tables printed on the instrument.

Œ-nom'e-ter. A hydrometer adapted to determine the strength of wines.

Off'al-dry'er. The bones, offal, manure, or other material to be dried, being passed into the rotary cylinder, are caused to traverse the same throughout

Fig. 3366.



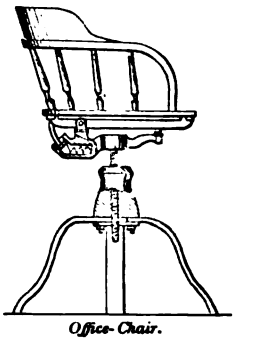
Offal-Dryer.

and discharged at the end adjacent to the fan. The hot fan-blast, together with the steam and offensive gases, may be allowed to pass off directly through the chimney, but by closing a damper they may be conducted to the fan and driven into the ash-pit of the furnace.

Off-cut. That part of a sheet which is cut off before folding, and then placed within the other previously folded portion. This occurs in some modes of imposing.

Office-chair. Preferably a chair which may be raised or lowered by a screw, on which it may be rotated, and also admitting of being tipped back. Casters complete the list of adaptabilities, and leave but strength and sumptuous upholstery to be desired.

Fig. 3367.



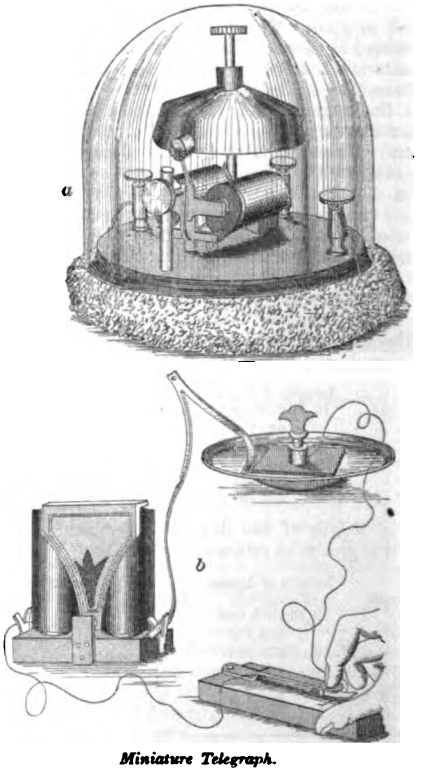
Office-Chair.

Office-tel'e-graph. A form of miniature telegraph for signaling from one room to another in a building.

It consists of a little electric bell, shown at *a*, Fig. 3368; these instruments are placed upon the desks in the various departments of an establishment, and from them wires extend to the desks of the managers, on which buttons are fixed, which connect with the wires. When the manager wishes to communicate with any particular person on the premises, he touches the button corresponding to the wire leading to the bell where the individual is at work. The touch sounds the bell, and, as a variety of signals may be sent, one bell may serve to signalize different persons who are within its hearing. This instrument, with bell, battery, and some yards of wire, is made for $5.

Another form of telegraph, shown at *b*, Fig. 3368, is used for purposes of experiment and instruction as well as communicating messages, and consists of an electro-magnet, sounding armature, a galvanic bat-

Fig. 3368.



Miniature Telegraph.

tery, telegraph-key, connecting-wires, and chemicals, all complete for working. The battery is composed

Digitized by Google

of two small plates, one of lead, one of zinc, the latter covered with paper as a septum, both plates set in a common saucer, in water in which a few grains of sulphate of copper are dissolved.

Off'set. (*Masonry.*) *a.* A ledge on the face of a wall at the point where its thickness is decreased.

b. A break or recess in a front, setting back from the general surface.

O-gee'. 1. A wave-like molding, having an inner and outer curve, like the letter S. Swelling in the upper part and hollow below, is the *cyma-reversa;* hollow in the upper part and swelling below, is the *cyma-recta.* (See MOLDING.) In its peculiar forms, or with other members of peculiar character, the ogee is known as *rampant ogee, quirked ogee,* etc.

2. A pointed arch, the sides of which are each formed of two contrasted curves. See ARCH.

O-gee'-plane. A joiner's plane for working ogee-moldings.

O'give. Arches or branches of a Gothic vault, which, instead of being circular, pass diagonally from one angle to another, and form a cross with the other arches which make the sides of the squares, whereof the ogives are diagonals. The middle, when the ogives cut or cross each other, is called the key, sometimes carved in the form of a rose. The members or moldings of the ogives are called nerves, branches, or veins; and the arches which separate the ogives, double arches.

Oil-bag. A sack of horsehair or cocoa-nut fiber, used in pressing oleine from the stearine in a press.

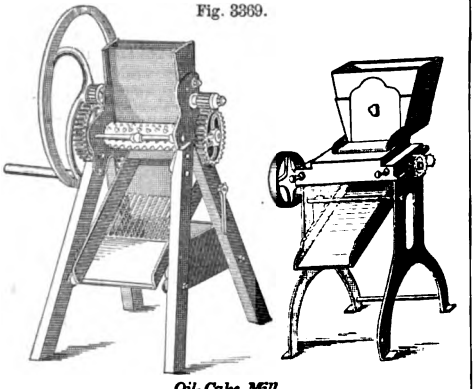
Oil-box. A box containing a supply of oil for a journal, and feeding it by means of a wick or other device. An *oil-cup.*

Oil-cab'i-net. A box or reservoir in which oil is kept in store, either by a retail dealer or in the storeroom of a factory or machine-shop. Cans or oilers are filled from the cabinet by means of a small pump.

Oil-cake. The marc or refuse after oil is pressed from flax, rape, or hemp seed; or from cocoa-nut pulp. Used for cattle-feed or manure.

Oil-cake Mill. A machine to crumble flaxseed oil-cake as a food for stock. The illustration shows

Fig. 3369.



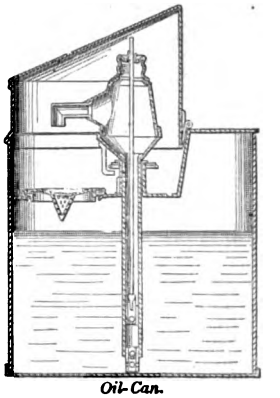
Oil-Cake Mill.

a machine with a pair of studded rollers which may be set at such a distance apart as shall give the result required. The machine may be set to nine different grades of fineness without affecting the mesh of the gearing.

The other illustration is a machine to be run by band and pulley.

Oil-can. 1. One for storage of oil, from which it is withdrawn for sale or use, as the case may be. In the example, the oil-can from which the oiler is filled is placed in the tray, whose floor has an opening for the stock of the pump, which is steadied by a sleeve, and held down by a hook, which engages a flange on the sleeve.

Fig. 3370.

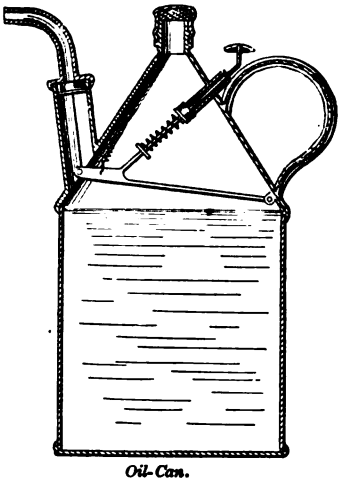


Oil-Can.

2. One for holding oil for supplying lamps, oil-cups, or journals, as in the example, Fig. 3371, in which the spout and vent-hole have stoppers projected against their outlets by the spiral springs and pivoted bar. The sliding trigger opens both at once.

3. An *oiler* for lubricating bearings; one on a larger scale is shown in Fig. 3372, in which the tubular handle has a plunger, which is depressed by

Fig. 3371.



Oil-Can.

the thumb to force the oil from the nozzle. The plunger is connected to the stem of a valve near the point of the nozzle; the valve is opened simultaneously with the depression of the plunger.

For the smaller kinds of oilers, see OILER.

Another kind of oil-can is that in which oil in measured quantities is shipped and sold. The ingenuity in this case consists in the nozzle, in the means of making and fastening the joints, so as to be economical of material, ready in construction, and convenient in use. See also PAINT-CAN.

Oil-car. Oil-cars may be seen upon our railways carrying large cylindrical vessels resembling the Western two-flue steamboat-boiler, and with a dome at the midlength. Another form of car-tank is a frusto-conical vat, like a mash-tun; two or three of which are accommodated on a platform-car. Another form is like that in the figure, in which oblong square tanks are built so as to occupy the carbed, upon which they are fastened by cleats and stay-rods. The tanks are made of matched planks bolted together.

See OIL-TANK.

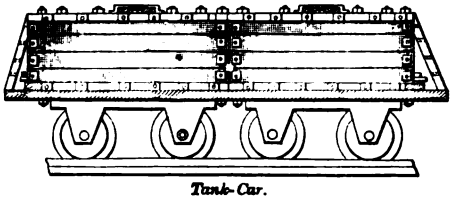
and contraction of the oil without overflow of the liquid or collapse of the tank.

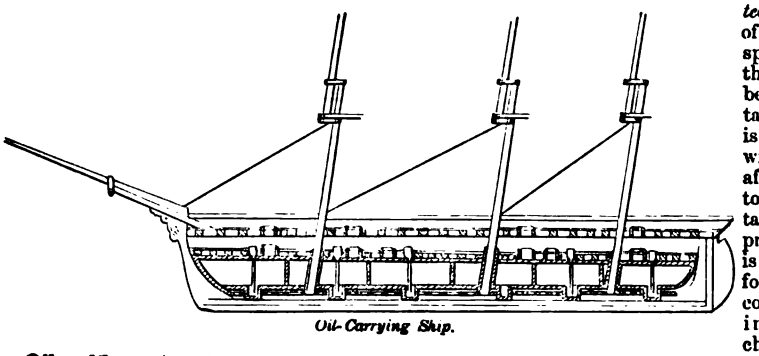
Fig. 3375.



Tank-Car.

Molasses is also carried in bulk from the West Indies to Portland and elsewhere.

Fig. 3376.



Oil-Carrying Ship.

Oil-cel'lar. An oil-reservoir in the bottom of a journal-box.

Oil-cloth. A tarpaulin.

Painted canvas for floor-covering. The latter description is prepared from cloth especially woven for the purpose, frequently of great width, and covered on each side by a peculiar series of processes, with paint. Figures or patterns in oil-colors are afterward printed on one side by means of wooden blocks. See FLOOR-CLOTH.

Floor oil-cloth is manufactured from jute, made principally at Dundee, Scotland. This is woven into widths of frequently from 18 to 24 feet, in looms at which two men, one on each side, are employed in throwing the shuttle. The length of the warp often exceeds 100 yards. The pieces are cut to the desired size, and these smaller pieces are stretched upon upright wooden frames, each of which has a series of scaffolds, reached by a ladder at one end of the frame.

When the canvas is perfectly stretched, a weak solution of size is laid on with a brush, and while yet damp it is well rubbed with pumice-stone, filling up the interstices between the threads and preventing the paint from penetrating too far, so as to render the fabric brittle. When this is dry the paint, which is of a very thick consistence, containing little or no spirits of turpentine, is applied in dabs with a short thick brush. These are then partially scraped off with a long elastic trowel, the paint at the same time worked into the cloth, leaving a level surface. This is allowed to dry from 10 to 14 days, when a second and sometimes a third coat of thinner paint is smoothly applied with the trowel, finishing the under side. In the mean time the other side, which is to be finished, is similarly sized and pumiced and a coat laid on with the trowel, and carefully pumiced so as to remove all knots or inequalities from the surface. To this succeed two more layers, each laid on with the trowel and rubbed with pumice, over which a fourth coat, called the *brush color*, forming the ground of the future pattern, is thinly laid on with a brush.

The whole series of operations occupies from two to three months, and when the final coat is dry the cloth is removed to the printing-room. The printing is performed on a long flat table, by means of engraved wooden blocks, the cloth being drawn along the table as required.

One block is required for each color forming the pattern.

The process is thus performed: A number of cushions, one for each color, is placed upon a table, and by the side of each cushion is a pot of color. The cushions consist of a pad of flannel covered with smooth floor-cloth. A boy, called the *tierer* or *tearer*, takes up a portion of color on a brush and spreads it evenly over the cushion. The cloth being spread upon the table, its upper surface is slightly roughened with a steel scraper and afterward with a brush, to enable it better to take the color. The printers, each of whom is provided with a block for containing a separate color, follow one another in succession; each charging his block by pressing it down on the cushion. The first takes it to the cloth and, applying it to his part of the pattern, hits it several taps with the handle of a heavy hammer, leaving an impression in one color only; the second, third, etc., follow, each printing in a similar way his own portion of the pattern in a different color from his predecessor. As the work proceeds the cloth is turned over and descends, through an

Digitized by Google

opening in the floor, to the drying-room, where it sometimes remains several months.

Oil-cock. A faucet admitting oil from an oil-cup to the journal. See OIL-CUP; LUBRICATOR.

Oil-cup. When portable, for oiling machinery, they are considered as OILERS (which see). When attached to a boxing, or otherwise permanent, and devoted to a special bearing, valve, piston, etc., they are considered as LUBRICATORS (which see). Devices for holding oil, in which capacity and storage are elements in their usefulness, are considered under OIL-CAN; OIL-TANK; OIL-CAR.

Oiled Leath'er. Leather dressed with oil; as CHAMOIS-LEATHER (which see).

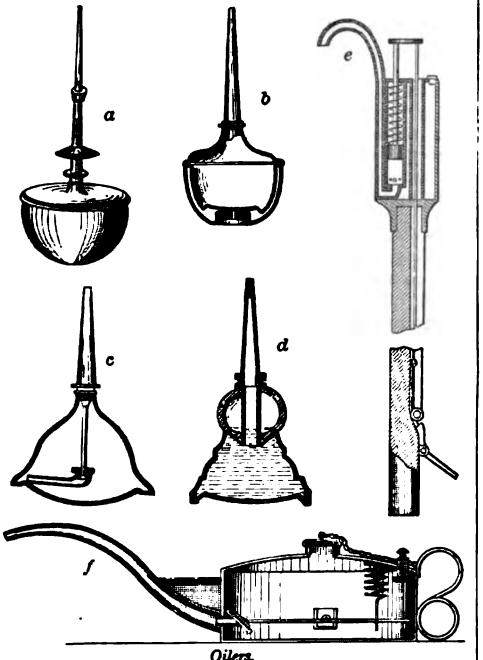
Oiled Pa'per. Transparent paper used for tracing. See TRACING-PAPER.

Oiled Silk. (*Fabric.*) Silk which has been treated with a boiled oil, so as to render it water and perspiration proof. Used as sweat-pads, as a lining in hats and bonnets to resist the perspiration, and over wet dressings of wounds to prevent evaporation.

Oil'er. A can for applying oil to a journal. From the numerous forms the following may be selected:—

a is Olmstead's oiler, made of thin sheet-metal,

Fig 3377.



Oilers.

the bottom of the bulb being weighted so that it always stands upright.

b is Broughton's oiler, having an outer shell, an internal reservoir of elastic material, and an opening in the bottom for a thumb-piece, by which the reservoir is compressed to discharge oil.

c has a swiveled tube attached by an elbow to the discharge-tube, and which reaches the oil collected at the lower portion of the can when tilted.

d has a transparent chamber between the nozzle and the reservoir.

King's oiler, *e*, is for reaching shafting in an elevated position; the oiler is placed on the end of a handle, and the oil ejected at the goose-neck by a plunger actuated by a wire and a trigger-lever on the handle.

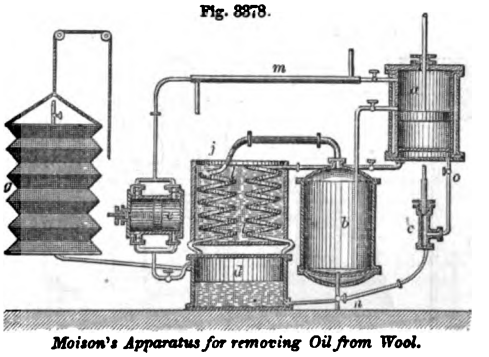
f is an oiler for large machinery, steamships, etc. It is air-tight, and will not discharge when upset, nor when tilted, until the air-valve is pressed by the thumb, although the spout is always full.

An early form of this useful little appliance is to be seen in the British Museum. It is a small horn with a plate on the end, and a nozzle through which the oil exuded. Whether the flat end at the base of the horn is elastic, so as to assist in ejecting the oil, does not appear. It was found at Thebes by Mr. Burton, associated in a basket with several other carpenter's tools, all of which are in the same magnificent collection. The other tools are chisels, drills, drill-bow, saws, mallet, and nail-bag. See cut under MALLET.

Oil-ex-tract'ing Ap'pa-ra'tus. Other than the grinding-mill and press, chemical means have been used for extracting oils from seeds, nuts, grain, fruit; also oil from wool. The seeds or nuts are crushed or ground, immersed in bisulphide of carbon, which extracts the oil and resin they contain, but leaves the substance otherwise unaltered. The solution is then removed, the bisulphide distilled off, leaving the oil, like the raw oils extracted by pressure, contaminated to some degree with resinous and coloring matters, which are removed by a second process of refining.

This process was invented by Moison of Mouy, in France, and used by him in cleansing wool from the

Fig. 3378.



Moison's Apparatus for removing Oil from Wool.

suint, as also from the grease and tar with which the sheep had been treated or marked. It was afterward adopted to separate oils, fats, and resins from the substances with which they are combined, and for supplementing the mechanical processes by operating upon oil-cake, the marc of olives, etc.

In Moison's process the wool to be subjected to treatment is introduced into a cast-iron cylinder *a*, surrounded by a jacket into which steam may be conducted when it is necessary to raise the temperature. 214 pounds of wool are placed in this cylinder at once. Within the cylinder is a false bottom perforated with numerous holes, with a small free space beneath it. Upon the top of the wool is placed a circular follower or compressor, fitting the interior of the cylinder, and perforated also with holes like the false bottom. Three rods connected with this follower pass through stuffing-boxes in the lid, and may be driven downward by means of fixed screw-nuts, the rods having screw-threads cut upon their prolongations above the cylinder to compress the wool to about one half its original volume. The lid being luted on, bisulphide is introduced by

Digitized by Google

pump *c* from reservoir *d*, forced through the layer of wool and overflows into the still *b*, where it is volatilized by steam in the jacket. The vapor of the bisulphide is conducted from the still to the refrigerator *j*, where it is condensed in the spirals *l l* and returned to the reservoir *d*. When no more oil comes over, the pump is stopped, the vessel *a* discharged by the stop-cock *o* leading to reservoir *d*, and the oil remaining in the still from the distillation of the bisulphide is withdrawn at the stop-cock *n*. The proper changes of stop-cocks being made, the air-pump *e* is brought into requisition to fill the upper portion of chamber *a* and drive the bisulphide downward out of the wool. To make this more complete, at the latter stages, the air from pump *e* is led through the steam-jacketed chamber *m* to enable it to volatilize the bisulphide of carbon in *a*. *g* is a gas-holder to hold any superfluous gas, to keep the capacity adjusted to the varying volume of the contents. The boiling-point of the bisulphide of carbon is 118° Fah.

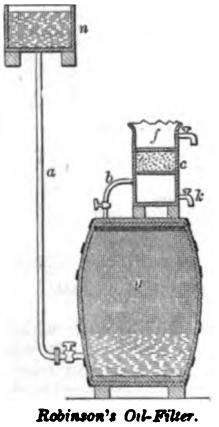
The process is adapted to dissolving the oils contained in the strippings of machine-cards in factories, and saving the waste from the axles of car-boxes, the journal-boxes of machinery. See also Sim's and Hutchinson's processes and machines, patented 1869, 1870, 1871. These are also particularly intended for extracting fusel-oil from grain.

Oil-fil'ter. Robinson's oil-filter acts by the upward pressure of a column of water below the oil.

The operation is as follows: —

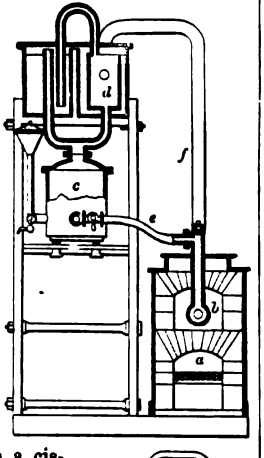
The butt *g* of oil being placed on a stillion, communication is made with its lower portion by means

Fig. 3379.

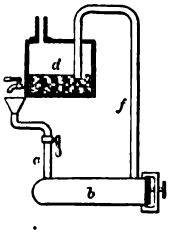


Robinson's Oil-Filter.

Fig. 3380.



of a pipe *a* leading from a cistern of water *n*. As the water flows into the butt, it displaces the oil, which passes by pipe *b* to the lower chamber of the filter which stands on the head of the butt. It thence passes through the perforated plate, a body of charcoal *c*, and a second perforated plate, to the upper chamber *f*, from whence it is discharged by the faucet. Impurities in the lower part of the filter are discharged by the faucet *k*.



Oil-Gas Apparatus.

Oil-gas. Gas was distilled from oil by Dr. Henry in 1805; and from refuse oily and fatty matters by Taylor, and patented in 1815.

The apparatus for the distillation of oil to obtain a permanent gas consists of a furnace *a* and retort *b*, the latter being charged with coke or brick, on whose heated surfaces the oil drips continuously from a reservoir.

The retort is a cylindrical vessel with a luted cover, and the oil is supplied in graduated quantities through a pipe *e* from a copper reservoir *c*. The gas evolved passes by an eduction-pipe *f* to a cistern, where, after passing through water, it is led by a pipe to the holder. The reservoir *c* also serves to receive the oil which may condense in the gas-holder *d* above. The double walls of the gas-holder contain water to cool the gaseous products of distillation.

There are many minor variations of the apparatus, but it is a simple process, requiring an occasional change of the coke.

Oil-gild'ing. A process of gilding in which the gold-leaf is laid on a surface prepared by a *priming* of whiting and size; several coats of *clear cole*, or transparent size; and an upper surface of *oil-gold size*, made of boiled linseed-oil and ochre, laid on by a brush. See GILDING.

Oil'ing. (*Wool.*) A stage in the manufacture of wool, which is first *opened* by the *devil* or *willy*, and then *burred* in a machine to remove impurities. The *oiling* follows, to prevent the fibers from becoming felted in the subsequent *scribbling* and *carding*.

Oil-leath'er. (*Leather.*) Oil-leather is prepared by currying hides in oil. Neat's-foot oil is used, but fish-oil is more commonly employed; to this the French add potassa. It is both more economical and more effective. The hides are somewhat moist, that the oily matters may be gradually and thoroughly absorbed.

"A coating of oil is uniformly spread over the grain and flesh sides, after which the hides are hung up to dry, the direct rays of the sun or too violent a draft being guarded against. In summer time the drying is effected in 12 hours, in winter it may extend to 3 or 4 days. When dry, the hides are again fulled, oiled, and dried. This is repeated. Finally, the grain-side is cleansed by rubbing it well with a brush and weak potassa lye. The coloring of the grain or flesh side, as the case may be, follows these operations, and is effected by a dye." As, for instance, the solution of sulphate of iron, which unites with the gallic acid of the tan to produce a black dye. "After receiving one coat the leather is pommeled crosswise; another layer of blacking is applied; dried, pommeled, or stretched, according as it is deemed necessary; rubbed over with a cork pommel to give it a smooth surface, and finished by giving a light coat of oil on the hair-side." — MUSPRATT.

Oil-mill. There are several varieties of oil-mills: —

1. With cylindrical rollers rotating on parallel axes and with their peripheries in contact, or nearly so. These rollers are of cast-iron, turned truly in a lathe, and with gudgeons running in brass boxes in the cheeks of the frame. A difference of speed adds a certain grinding action to the mere forcible pressure, and may be attained in one of two ways: —

a. By giving an equal axial speed to the rollers, which have varying diameters; or

b. By driving rollers of equal diameter at varying axial speeds.

The variation in speed is best attained by an unequal number of teeth in the driving-pinions.

2. Another form of oil-mill is the ancient *Phœnician* or *Chilian mill*, which has two rollers journaled to a horizontal shaft projecting from a vertical and

Digitized by Google

rotating post, the peripheries of the rollers traversing on a flat circular bed.

This is a grinding and crushing action, inasmuch as the flat face of the stone is parallel to the axis, and the portions of the face farthest from the vertical axis of revolution tend to traverse farther than the portions nearest to the said axis, so that, a compromise being effected, one portion or the extremes of each are obliged to rub as they rotate. The same principle is involved in this that is found in the traversing of a curve by the pair of wheels of a railway car. The wheel traversing the outer rail of the curve has farther to go than the inner wheel, and the latter will compel the outer one to slip back or the outer one will slip the inner wheel forward, — if the rails be in a horizontal plane. This brings a torsion on the axle, and is a fruitful cause of accidents; but is a valuable feature in the Chilian mill, so called, as it tends to mix and macerate the material, instead of packing it into a cake. See CHILIAN MILL.

The rolling-mill is sometimes employed as a preliminary, in the case of seeds with compact and slippery rind, such as those of flax and rape. Such seeds may then be subjected to the first expression, for the first quality of *cold-drawn oil*.

The press for the expression of the oil may be worked by screw, wedge, or hydrostatic power. See HYDROSTATIC PRESS; SCREW-PRESS; WEDGE-PRESS.

The magma after the first expression may be reground in the *Chilian mill*, or subjected to vertical stamps, which mash the seeds in mortars placed beneath them. See STAMPING-MILL.

The first and second expressions of oil having been obtained cold, the magma is now subjected to heat in a pan, being constantly stirred by a machine-driven spatula. It is then ready for the third pressure, which is final, if the resulting cake is to be used for cattle-feed. If, however, the last atom of grease is to be obtained, the magma is boiled, and the result of the fourth expression is so complete that the cake has no value except as manure.

In this recitation of processes it must not be overlooked that the repetitive method is only used where the various grades are required, and the system varies with different seeds and nuts. The resulting oils derived from the pressure of different vegetable productions bear different values, and the plans adopted vary to some extent with the kind.

It is common in the case of flaxseed, which leads the list in point of importance, to grind and heat the seed and then subject it to the hydrostatic press, securing all the oil at a single or once-repeated pressure.

Castor-oil is valued more highly, and is cold drawn, or should be.

A list of the more important expressed oils is given, with some particulars as to each.

Variety.	Quality.	Specific Gravity.	Oil per cent. Ure *et al.*

OILS, WAX, ETC.

Common Name.	Botanical Name.	Native Place, or where chiefly grown.	Qualities, Uses, etc.
Almond	Amygdalus Communis	S. Europe, etc	One of the finest of fixed oils; used chiefly in medicine.
Argan	Argania syderoxylon	Morocco	Obtained from the kernels of the fruit; resembles olive-oil.
Beech	Fagus sylvatica	Europe	The mast affords an oil used for burning and in cooking.
Ben	Moringa pterygosperma	India and Arabia.	Oil from the seeds of the horse-radish tree. Used in perfumery and by watchmakers on account of its not readily freezing.
Birch	Betula alba	Europe	Bark affords an oil by distillation. Used in the prepara-
Brazil-nut	Bertholletia excelsa	Brazil	Used for burning in lamps. [tion of Russia leather.
Butters			Term applied to the semi-solid greasy substances that exude from trees, as shea-butter, butter and tallow tree, vegetable butter, etc. Used for cooking and burning.
Cacao	Theobroma cacao	Hot climates	The "cocoa-nibs" of the shops. Used as a beverage. Afford an oil or butter which can be used for burning.
Camelina	Camelina sativa	Europe, etc	Oil from the seeds. Used for burning in lamps.
Candleberry	Myrica cerifera Myrica cordifolia	N. and C. Amer. Cape of G. Hope	The berries contain a wax-like matter, which is converted into candles, producing an aromatic odor as they burn.
Candle-nut	Aleurites triloba	S. Sea Islands	Seeds contain oil Used for food and for burning in lamps. Are strung on sticks by the natives, and so used as candles.
Carapa	Carapa guineënsis	W. Africa, etc	Seeds afford oil used by the natives for burning and anointing. In S France made into soap.
Cocoa	Cocos nucifera	Hot climates	The oil of the cocoa-nut is the chief material from which composite, stearine, and other candles are made. Used also in soap-making and for "railway grease."
Colza	Brassica campestris	Europe	Seeds of a variety of the cabbage tribe afford this oil. Used in lamps; largely used in lighthouses.
Cotton	Gossypium herbaceum	Hot climates	Oil used for burning.
Crab	(See Carapa.)		
Dodder	(See Camelina-oil.)

Common Name.	Botanical Name.	Native Place, or where chiefly grown.	Qualities, Uses, etc.
Fusel	Triticum, etc	Europe, etc	Seeds produce a peculiar oil. It gives the flavor to raw whiskey and is used for making flavoring extracts. Formerly used for burning.
Gingilie	(See Sesamum.)		
Ground-nut or earth-nut	Arachis hypogœa	Europe, etc	Affords oil used in cooking, burning, and for making soap.
Hazel	Corylus avellana	Europe, etc	Nuts afford oil. Sold as "nut-oil." Used by painters, perfumers, and medicinally.
Hemp-seed	Cannabis sativa	Europe, etc	Used for burning, paints, varnishes, and for soft soaps, etc.
Insect wax Japan wax Java wax	(See Wax.)		
Linseed	Linum usitatissimum	Europe, etc	Boiled with litharge produces the "boiled oil" of paints and varnishes. Used in burning, etc. The refuse of the seeds affords the oil-cake for fattening cattle.
Maize	Zea mays	Warm climates	Oil extracted from the seeds.
Mee	Bassia longifolia	Tropics	Obtained from the seeds. Used for burning, etc.
Myrica wax Myrtle wax	(See Candleberry.)		
Mustard	Sinapis alba et nigra	Europe, etc	The husks and seed afford a fixed oil. Used for burning in lamps, etc.
Naneel	Bassia latifolia	Tropics	Oil obtained from the seeds. Used in burning, etc.
Nut-oil	(See Hazel and Walnut.)		
Olive	Olea europœa	Europe, etc	One of the purest of vegetable oils. Used in the arts and for salads. In Italy is used in lamps.
Palm	Elais guineensis	W. Africa	The fruit affords the palm-oil used in candle and soap making.
Pine	Pinus sylvestris	Europe, etc	Leaves afford an oil which can be made into soap.
Poppy	Papaver somniferum, var. nigrum	India, etc	Oil used extensively in the arts and for adulterating more expensive oils.
Rape	Brassica oleracea, etc	Europe, etc	Extensively used for burning in lamps. Colza is similar to it. When refined is equal to sperm-oil.
Sesamum	Sesamum indicum	India, etc	Seeds afford an oil used in India for cooking, burning, anointing, etc. Elsewhere used in lamps and for making soap.
Shea butter or oil	Bassia parkii	W. Africa	Seeds afford an oil used in Europe for candle and soap making, etc.
Souari-nut	Caryocar nuciferum, etc.	S. America	Contains a sweet oil. Much used in S. America.
Sunflower	Helianthus annuus	Europe, etc	Seed yields an oil. Used in making fancy soaps, etc.
Tallow (vegetable)	Pentadesma butyra	Sierra Leone	Tallow, a term often applied to solid fatty substances obtained from plants. That produced from the seeds of the *Stillingia sebifera* is used for candles by the Chinese.
	Stillingia sebifera	China	
	Bassia butyracea	N. India	
Walnut	Juglans regia, etc	Europe and America	An oil often sold as "nut-oil." Used in the arts and to adulterate other oils.
Wax (bees)	.....	....	Beeswax, although not strictly a vegetable production, is primarily derived from the pollen of flowers.
Wax (insect)	Fraxinus sinensis	China	A kind of wax deposited by an insect, the *coccus pe-la*, on the leaves of this species of ash.
Wax (Japan)	Rhus succedanea	Japan	A vegetable wax afforded by the fruit of the tree. Used in candle-making
Wax (palm)	Copernicia cerifera	Brasil	Wax obtained from the surface of the young leaves of the plant.
	Ceroxylon andicola	Andes	Wax obtained by scraping the trunk of the tree. Used with tallow to make candles.
Wheat-oil	(See Fusel-oil.)		

Essential Oils.

Aniseed	Pimpinella anisum	Europe, etc	Seeds afford an oil used in medicine and flavoring spirits for liquors.
Bergamot	Citrus aurantium	S. Europe, etc	Rind of fruit affords an oil. Much used in perfumery, essences, etc.
Cajeput	Metaleuca cajeputi	Moluccas	A volatile oil which dissolves india-rubber.
Camphor	Camphora officinarum	China, etc	A solid essential oil. Used in medicine, etc.
Cedar	Cedrus rubra	Generally	Wood yields an essential oil. Used in perfumery, etc.
Chamomile	Anthenus nobilis	Europe	The dried flowers afford an essential oil.
Citron	Citrus medica	Europe	Fragrant oil. Used by perfumers.
Citronelle	Andropogon citratum	India, etc	Obtained from lemon-grass. Used in perfumery.
Clove	Caryophyllus aromaticus	Tropics	Fragrant oil. Used in perfumery.
Fennel	Fœniculum vulgare	Britain, etc	Used in medicine.
Grass	Andropogon (various)	India	Obtained from various Indian grasses. Used in perfumery and medicine.
Jasmine	Jasminaceæ	Asia, Europe	A perfume. Obtained from the flowers by placing them in tallow and extracting by means of alcohol the volatile principle.
Lavender	Lavendula vera et spica	Europe	Oil used largely in perfumery and medicine.
Lemon-grass	Andropogon citratum	India	A delicious essential oil.
Lemon	Citrus limonum	Warm climates	The rind affords an oil used in perfumery, flavoring, etc.
Neroli	Citrus (various)	Europe	Perfumed oil obtained from various species of the orange family. Affords the "orange-flower water" of the shops, etc.
Nutmeg	Myristica moschata	Moluccas, etc	Essential oil. Used in perfumery.
Otto or attar of rose	Rosa moschata Centifolia, Damascena	Turkey and Syria	A fragrant oil obtained from the Eastern species of rose.
Orange	(See Bergamot, Neroli.)		
Patchouli	Pogostemon patchouli	India	Plant affords an oil. Used as a perfume.

Common Name.	Botanical Name.	Native Place, or where chiefly grown.	Qualities, Uses, etc.
Peppermint-oil.....	Mentha piperita.....	Britain, etc.....	Used in medicine.
Rosemary.....	Rosmarius officinalis...	Europe, etc.....	Tops of plant afford an oil. Used in perfumery, medicine, etc.
Sandal-wood or santal-wood	Santalum	India.....	Yields an essential oil heavier than water. Used in perfumery.
Winter-green	Gaultheria procumbens.	N. America.....	The plant affords an essential oil. Used in medicine, perfumery, and for flavoring.

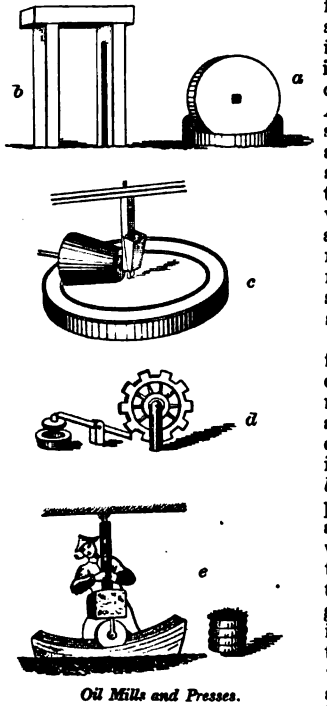
The most ancient oil-mills are those used for mashing the olive. They were used in Palestine at a very early date. Although Solomon, A. D. 1015, supplied Hiram with 20,000 baths of oil, in addition to the grain and wine, in return for the "timber of cedar and timber of fir," yet the Phœnicians themselves were great cultivators of the olive and traders in oil. The means they used were the mill, such as we now call the "Chilian," followed by a lever-press. The stones, bed-plates, and press-frames yet remain in the country to attest the fact.

Olives were known in ancient Egypt, and their cultivation was imported thence into Greece. Cecrops (1556 B. C.) is credited with the introduction of the tree, and Aristæus the Athenian (1450 B. C.) was deified as the inventor of expressing-machinery.

They were introduced into Italy about 562 B. C., during the reign of Servius Tullius, which was coeval with that of Nebuchadnezzar, and with the prophecies of Daniel. This was nearly 100 years before Marathon.

The Phœnician mill is shown at *a* in the accompanying cut, which is taken from Thompson's Researches in Palestine. It is drawn from one at Em el' Awamêd. The stone wheel had an eye for the shaft, to which the draft animals were attached, and the fruit was mashed by the revolution of the stone in the basin.

Fig. 8831.



Oil Mills and Presses.

The press-frame (*b*) consisted of two upright posts and a very heavy cross-piece, being evidently a *beam* or *lever* press. A beam above the platen which rested on the olive-cheese traversed in grooves on the inner faces of the posts, and was depressed by a weighted beam. This was before Archimedes and the screw.

The basin represented is 8 feet in diameter, and a stone trough in the vicinity was doubtless used to receive the oil as it flowed from the press.

The basins and posts with huge stones on top are numerous in some sections of Palestine, where the long-lived olive has rotted away and left no trace. 2,400 years have passed since these lands were fully tended; the Assyrian, Persian, Greek, Roman, Saracen, and Turk have overrun the land, and the modern Syria is now occupied by a million and a half of people divided, by race or religion, into 16 tribes, who are Ishmaelites in *deed* and many of them in *blood*.

The Spanish olive-mill (*c*) is used for crushing that fruit to obtain the oil, which stands instead of butter and lard in a land that once afforded Columella a subject for praise in the conduct and productions of the dairies of Andalusia. The Spain of to-day is not what it was in the time of Cato, nor indeed what it was under the occupancy of the Saracens. It has probably retrograded in health, wealth, morals, productiveness, and in scholastic and executive ability.

Loudon remarks, that although the olive is grown in Spain in greater perfection than in Italy, owing to some manorial rights or a system of farming the taxes, all the olives of a district are brought to one place to be ground and pressed; and as each heap has to wait its turn, the olives in many of the heaps become black and rancid.

A friend of the missionary W. M. Thompson, who farmed the district of el Mughar, near the lake of Tiberias, states that a black color does not hurt the olives as they lie in the heap. The modern Syrian plan embraces two modes of grinding the fruit and expressing the oil: —

1. The *m' aserah*, which is worked by hand and used for grinding the early fruit before the streams are raised by the winter rains which start the water-mills. In the *m' aserah* the fruit is ground by a revolving stone in a stone basin, much as in the ancient Phœnician method just described. It is pressed in a beam or screw press, the mass being packed into straw baskets, which are piled one above another in the press. The cheeses, after one pressure, are broken up, put in copper pans over a fire, sprinkled with water, heated, and re-pressed.

2. The *mutruf*, driven by water-power, and pounding the olives with a stamp in a heated, vertical stone cylinder. The face of the stamp is of iron cross-bars, and it is rotated as it works. The mass is taken out below, put in baskets, and pressed. The process is repeated. The details of the operation are probably almost identical with those in vogue 3,000 years ago.

In China, the pestle and mortar (*d*) are used in reducing to powder the seeds of the oil-bearing tea-plant. The meal is boiled in bags and pressed to yield the oil. The lever is tripped by the cogs of the sprocket-wheel, and falls by gravity.

e shows the press used in China in crushing the seeds of the tallow-tree. The weighted wheel is suspended by a rod from a beam, and is oscillated to and fro by the workman, traveling upon the seeds which are placed in the trough below. The oil procured from the bruised seeds by heat and pressure is added to vegetable oil and wax to the required consistence for candles.

b, the amount being regulated by an adjustable plate, and pass between the crushing-rollers *c d*, the smaller one of which has adjustable bearings, so that the distance between them may be varied. The larger roller is driven by belt and pulley, and has a spur-gear which moves the smaller one.

B shows a mill, heater, and press combined.

Fig. 3383 is the olive-mill of Barbary.

Fig. 3383.

Olive-Mill of Barbary.

Oil-of-brick. An empyreumatic oil used by lapidaries as a vehicle for emery, by which precious stones are sawn or cut.

The brick is soaked in oil and subjected to distillation at a high temperature.

Oil-painting. The process of painting with colors held in solution by volatile or evaporable oils which, on drying, leave the pigment combined with the solid constituents of the oil, upon the surface to which it has been applied.

Linseed-oil was undoubtedly used as a medium for painting in very early times, but the term "oil-painting" has by custom become restricted to the fine arts.

The pictorial representations of the ancient Egyptians were executed upon a ground of plaster or calcareous wash; the colors, according to modern analysis, were mixed with a resinous size or animal glue, and the whole covered with a coat of varnish.

Analogous substances for holding and fixing the colors appear to have been in use down to the latter part of the thirteenth or early part of the fourteenth century.

The oldest painting in oil-colors at present known was painted in the year 1297, by Thomas de Mutina or de Mutterfdorf, in Bohemia. It is in the Imperial Gallery of Bohemia. Two other paintings are in the same collection, by Nicholas Wurmser of Strasburg, and Thierry of Prague, respectively.

These paintings antedate by many years those of Hubert and John Van Eyck of Bruges, who lived during the earlier part of the fifteenth century, and to whom the invention of oil-painting is generally ascribed.

Oil-press. A press for extracting oil from the seeds of various plants. Formerly, linseed constituted by much the largest source of supply, but within the past few years cotton-seed is largely used, it as well as linseed yielding a large proportion of oil, beside meal or cake well adapted for feeding cattle or hogs. Cotton-seed (excepting Sea Island) is preferably decorticated previous to being ground and pressed, otherwise the treatment of these and linseed is the same.

The seed is first passed between two rollers, one of which revolves more rapidly than the other, subjecting it to a drawing as well as a crushing action; from these it is transferred to the chasers, two heavy circular stones turning upon a third stone, and moistened with water to prevent the meal from adhering; when thoroughly ground it is put in a heater; of this there are several forms: that shown at *A*, Fig. 3384, consists of a cast-iron cylinder *c* supported by the brick foundation *a*, surrounded by a steam-jacket *d d*, to which steam is admitted through the pipe *h*, the water of condensation being drawn off through *i*. A charge of meal is introduced into the cylinder and agitated by a rotary stirrer stepped in the depression *e*; the steam is let on, and when a temperature of 180° to 190° Fah. is attained the gate is opened and the meal withdrawn, falling through the aperture *g* into a bag beneath; the bag being partially filled, its unfilled portion is turned over so as to close its mouth, and it is placed within a squeezer made of horsehair cord covered with leather, and having a handle attached by copper rivets. These are then introduced within the boxes *a a a* of the hydraulic press *B*, and subjected to pressure; *b* is the pump, and *c* the pipe by which its pressure is transmitted to the ram of the press.

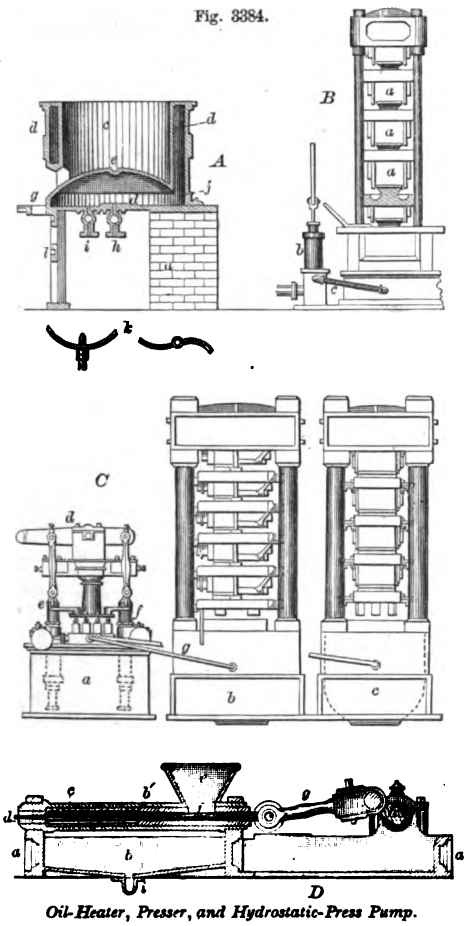
C represents Blundell's press, *a b* a side and *c* an end elevation; *d*, the operating-lever; *e f*, plungers and pump-cylinders; *g*, pipe transmitting pressure to the ram.

D is a plunger-press, to be presently described.

The product of oil is about 2 gallons from a bushel of linseed, or 56 pounds of hulled cotton-seed; that

Digitized by Google

Fig. 3384.



Oil-Heater, Presser, and Hydrostatic-Press Pump.

from Sea Island seed, which does not require hulling, is about 90 gallons from each 100 bushels.

"The oil-press was invented by Aristæus, the Athenian"; so says Pliny. To find the date at which he flourished, we must consult the marriage register. He was a son of Apollo, but married a daughter of Cadmus about 1450 B. C., let us say. He found time between his spells of running after Eurydice to instruct men in the culture of the olive and of bees. This was about the time of Joshua. Archæologists have shown it to be probable that the Phœnicians practiced both the arts before Aristæus destroyed the harmony in the household of Orpheus.

The oil-press used by the Phœnicians in the time of Solomon, and substantially in use at the present day in Syria and Palestine, consists of two posts and a very heavy lintel. The press is illustrated in OIL-MILLS (which see) in connection with the basin and revolving stone by which the fruit is ground. The crushed fruit in straw baskets was (and is) placed on a bed-piece, the platen adjusted, an upper beam laid upon the platen, its ends traversing in grooves on the inner faces of the posts as it was pressed down by a lever above. This accounts for the lintel being so heavy, as it was required to resist the upward thrust of the lever. The screw-press was then unknown.

The olive is a native of Asia, from which it has been transported to Africa and Southern Europe.

The wedge-press, which is sometimes used for expressing linseed-oil from the hot magma, is a somewhat crude but powerful press. The bags of ground seed are placed in bags between followers, which are driven toward each other by wedges driven in above and below.

The hydraulic press does not differ substantially from that employed for other purposes, and is described under HYDROSTATIC PRESS (which see).

In the English practice, the flaxseed is crushed between rollers, then ground beneath an edge-stone, heated, filled into bags, and then pressed in a wedge-press or a hydraulic press.

The castor-oil plant (*Ricinus communis*) was well known to the Egyptians, and is called *silli-cyprium* by Herodotus, and *kiki* by the inhabitants of Egypt. The oil was then extracted by pressure or by boiling, and used for anointing. It was probably Jonah's plant, *kikion*, being mistranslated *gourd*. Herodotus and Pliny claimed that it smelt badly, but had its uses medicinally.

Bessemer and Heywood's machine (*D*, Fig. 3384) for expressing oil from seeds (English) consists of a bed-plate or framing *a a*, cast in one piece and having a receptacle *b* for receiving the expressed oil. The frame supports a gun-metal cylinder *b'*, within which is fitted a tube *c*, having a spiral exterior perforated groove, and lined with an open-ended bag of coarse fabric containing a cylinder of wire gauze or perforated metal. The cylinder *b* is contracted at *d*, so as to support the interior tube against longitudinal pressure, and prevent the rapid escape of the pressed seed. The seeds are placed in the hopper *e*, and as the plunger *f* is drawn back by the connecting-rod *g* on the crank-arm *h*, a portion falls into the tube, and on its return movement is forced into the bag before described, where the seeds are crushed, a portion of the cake thus formed being at the same time expelled through the contracted end of the tube. The expressed oil passes through the openings in the inner and outer cylinders, whence it is withdrawn by the pipe *i*.

Oil-pump. A pump to raise oil from a can or reservoir and discharge it on to a journal.

Oil-re-fin'ing Ap'pa-ra'tus. The apparatus employed for separating the various ingredients contained in crude petroleum in the process of obtaining kerosene consist of an iron still having a wrought-iron worm-pipe, which is submerged in a tank containing cold water. The still having been filled with crude oil, a fire lighted beneath it causes the oil to boil, and drives off the more volatile vapors which at ordinary temperatures pass over without being condensed. By surrounding the coil with ice or by compressing these gases by means of an air-pump, they may be condensed into the form of very volatile liquids, termed *rhigolene* and *chymogene*.

After these have been eliminated, the vapors begin to condense in the coil, the resulting oil being received in a tank at its farther end. That first formed has a gravity of about 95° Beaumé, but the product becomes heavier as the process proceeds. It is usually customary to direct the stream into one tank until the gravity reaches from 65° to 59° B., forming crude naphtha, when it is diverted into the kerosene tank, into which it is allowed to flow until a gravity of about 38° B. is reached, or the oil becomes of a yellow color. This second fraction is the burning-oil, which requires a farther purification to fit it for use. The stream is next directed into the paraffine oil-tanks, and allowed to run until nothing remains in the still except coke. When, however, very large stills of 1,000 barrels capacity or upward are employed, the distillation is stopped when the

Digitized by Google

residuum has attained a tarry consistence, the remaining oil being extracted in smaller stills.

By slow distillation in high stills, the production of the heavier oils may be avoided, they being "cracked" into lighter oils, so that only crude naphtha, kerosene, and coke result.

The burning-oil is purified by the addition of about two per cent of sulphuric acid to improve the color and deodorize it. The acid is poured into the oil, and the liquid thoroughly agitated and then allowed to stand, when a dark tarry residuum separates. This is removed, and the clear oil is then agitated with water and afterward with caustic soda or ammonia. This neutralizes any remaining traces of acid, and is removed by water. In some instances it is then heated to expel a small proportion of naphtha or benzine which it may contain, or is redistilled.

The crude naphtha is redistilled for gasoline, benzine, or refined naphtha, or is poured into the oil-wells, nominally for the purpose of cleaning them. In some instances it is used for adulterating the crude oil sold to the refiner.

In the details of the process of refining, manufacturers somewhat differ. Some blow steam through the crude oil, thus taking off the naphtha previous to distillation. In other instances, the heavier portions of the distillate are separated, forming safer oils than those in ordinary use. Thus, "astral oil," averaging 49° B., flashes at 125° of Fahrenheit's scale, and "mineral sperm," having a gravity of 36° B., only yields inflammable vapor at temperatures above 262°.

Oil which flashes at or above 100° F. is considered safe for ordinary use, but the temptation to allow the heavier portion of the crude naphtha, an article which commands a much lower price than oil, to flow into the tank designed for the latter is so great that many kinds of oil in the market are very dangerous, their vapors exploding at a much lower point.

Instead of continuing the flow of naphtha into its proper tank until a gravity of 58° or 59° B. is attained, it is diverted into the burning-oil reservoir while yet as light as 63° to 65°.

Dr. White of New Orleans found that one per cent of naphtha added to an oil which flashed at 133° Fah. caused it to flash at . . . . 103°

2 per cent	92°
5 per cent	83°
10 per cent	59°
20 per cent	40°

Ordinary kerosene, having a gravity of 47° B., flashes at 86° Fah. An oil which will not flash below 100° may be made by running off the naphtha to 58° B., and exposing the oil in shallow tanks to the sun or a strong light for a day or two.

The average yield of crude Pennsylvania oil is stated to be : —

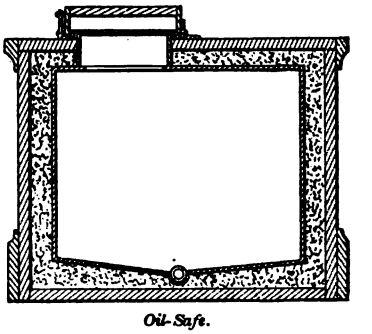
Gasolene	1½
Refined naphtha	10
Benzine	4
Refined petroleum or kerosene .	55
Lubricating oil	17½
Paraffine	2
Loss, gas, and coke	10
	100

By *cracking* it can be made to yield, —

Crude naphtha	20
Burning oil	66
Coke and loss	14
	100

Oil-safe. A storage-vessel for oil, protected from access of fire, and measurably from the heat of the surrounding atmosphere. It consists of a vessel of

Fig. 3385.



Oil-Safe.

sheet-metal with soldered joints in a box of wood with an intervening material which is a poor conductor of heat. Oil is poured in at the top and discharged by pipe and faucet at the bottom.

Oil-skin. Cloth treated with oil to make it water and perspiration proof.

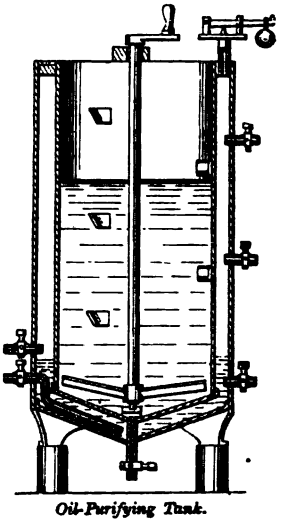
Oil-still. A still for hydrocarbons, notably petroleum. See PETROLEUM-STILL.

Oil-stone. A slab of fine-grained stone, set in a wooden block and provided with a wooden cover, used for imparting a keen edge to tools: it is so called because oil is used for lubricating its rubbing surface. See WHETSTONE. See list under GRINDING AND POLISHING.

Oil-tank. A large vessel for holding oil for —

1. Treatment.
2. Storage.
3. Transportation.

Fig. 3386.



Oil-Purifying Tank.

1. Tanks for treatment are usually large reservoirs or vats. Two illustrations may be given.

In Fig. 3386, the oil or fat is placed in the inner tank, which has a vertical shaft having radial stirrers and a discharge-pipe at its lower conical end. It is surrounded by a water or steam chamber, by which the oil or fat is heated to 90° or 100° Fah., respectively, and yeast, 3 parts, added to 40 parts of the grease. The whole is stirred while warm, and then left to ferment, when sediment is drawn off at the bottom. The tank may be used in the manufacture of stearine. See also LARD-TANK.

Fig. 3387 shows an arrangement of tanks for carrying out successively the operations of oxidizing, neutralizing, steaming and heating for evaporation, oils to be purified; and of special devices to be employed in connection with one or more of the tanks for the addition of oxidizing and neutralizing chemicals to the oils, for stirring and agitating the same, and for

Digitized by Google

indicating the condition of the contents of the several tanks.

The oxidizing-tank *A* is provided with a detachable stirring-shaft *H*, and diffusing-sieve *P*. On the next step is a neutralizing-tank *B* with sieve *P'* at top, and steam or hot-air pipes *Q* within the same. Third in the series is a steaming-tank *C*, containing suitable steam-jet pipes *R*, and fourth is an evaporating-tank *D*, the whole being adapted and made to operate

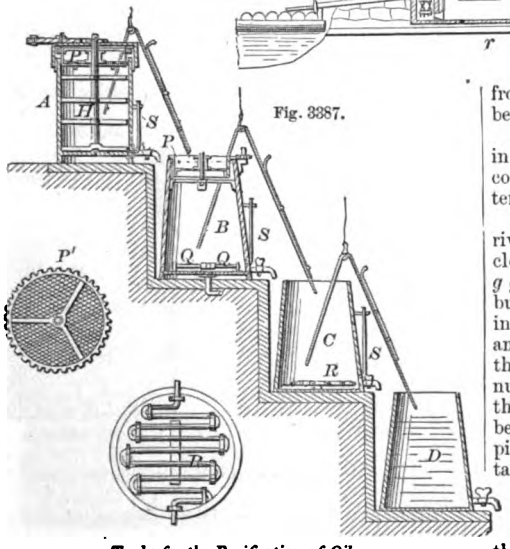


Fig. 3387.

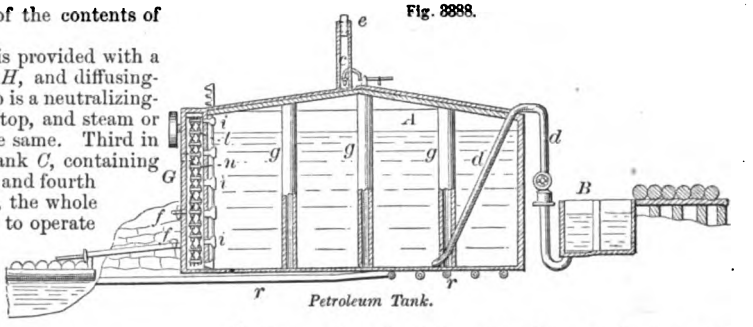
Tanks for the Purification of Oil.

consecutively upon the same body of oil as it flows from one to another in the series.

Each vat has its gage-glass *S*, and the discharge

Fig. 3388.



Petroleum Tank.

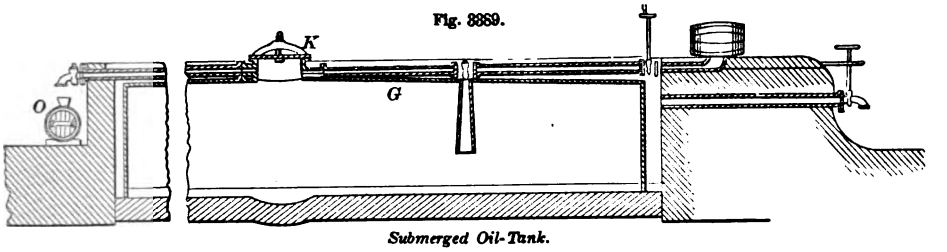
from each tank of the upper three to the one next beneath it is by siphon.

2. *Tanks for storage* are usually on a large scale, in obedience to the law of economy of material in construction, being much less per cubic foot of contents for large vessels than for small.

Fig. 3388 is a petroleum tank, shown as upon a river-bank. The tank *A* is of metal, is hermetically closed, and its roof is supported by hollow columns *g g*. Above is an escape where volatile gases are burnt as at a gas-burner. *B* is the receiving-tank into which the barrels of oil from the well are emptied, and from which the oil flows into the tank *A* through the siphon *d*. *G* is the delivering-chamber with a number of valves *i i* at different hights leading from the tank *A*, so that oil of different gravities may be drawn from different altitudes. The entrance-pipe *d* delivers the fresh oil into the bottom of the tank in contact with the heavier stratum of oil, depositing the paraffine at the bottom. *r* is a heating coil, for use if necessary. *f f* are delivering faucets to the pipe which leads to the barrels in the boat alongside the river-bank.

Fig. 3389 shows a form of submerged tank, the iron oil-chamber being placed in a pit with water around and above it. The oil is introduced and discharged by pipes. The induction and overflow of the water

Fig. 3389.

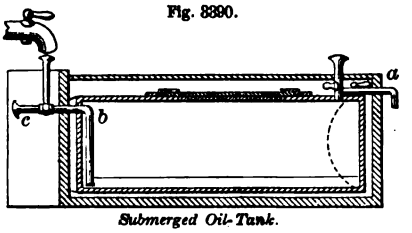


Submerged Oil-Tank.

is also by pipes. *K* is the man-hole cover. Water enters below the oil in the tank, the level being evidenced by a gage.

In Fig. 3390, the water in the submerged tank is

Fig. 3390.



Submerged Oil-Tank.

displaced by oil introduced from above; the stratum of water escapes by rising through a pipe *b* and overflowing. Oil is discharged at *a* by admitting water.

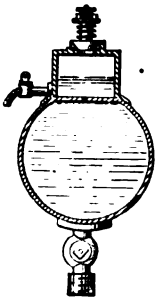
3. *Tanks for transportation* are made of a size to form a load for a platform, on which they remain, being filled and discharged by pipes and hose (see OIL-CAR); or are of such a size that they may be swung or rolled on to the car. The latter includes boiler-iron barrels, and those of wood, pitched or otherwise treated to render them impervious to oil.

Church's petroleum tank (Fig. 3391) has upon its top a chamber with a safety-valve to enable it to be kept full without endangering it when the contents expand or contract by changes of temperature.

In Fig. 3392 the tank has an air-chamber in any convenient part provided with a safety-valve. A bent tube extends from the petroleum-tank into the air-chamber, the ends terminating a short distance

Digitized by Google

Fig. 3391.



Church's Oil-Tank.

above the bottom of the tank and air-chamber. The tank is filled with petroleum, and enough is placed in the air-chamber to cover the end of the bent pipe under all circumstances of expansion and contraction, so as to prevent the accession of air to the main chamber.

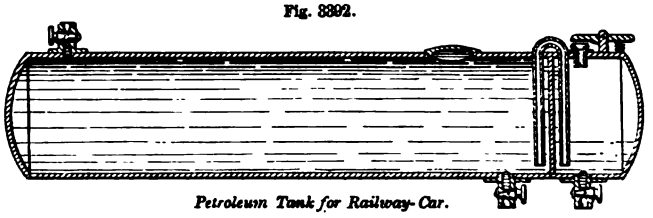
As the petroleum expands it flows into the air-chamber, condensing the air; as contraction of its bulk occurs it flows back to the main reservoir.

In Fig. 3393, the safety-chamber is introduced to afford a space into which the oil may expand, and from which it returns when contracting. The chamber is detachable and capable of introduction into the tank or barrel at the ordinary opening for filling.

Other forms of tanks for transportation are built of metal, inside box-cars, with devices for staying, filling, emptying, etc.

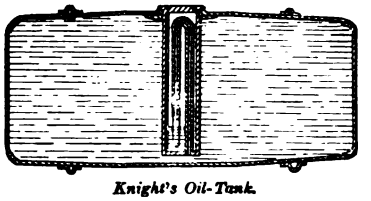
Much ingenuity has been expended in making barrels of wood or of metal for shipping petroleum and coal-oil.

Fig. 3392.



Petroleum Tank for Railway-Car.

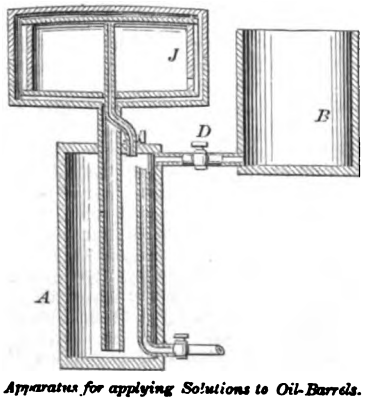
Fig. 3393.



Knight's Oil-Tank.

Day and Chapman's metallic barrel is inclosed in one of wood.

Fig. 3394.



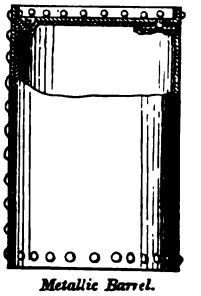
Apparatus for applying Solutions to Oil-Barrels.

Fig. 3394 shows an apparatus for applying solutions to oil-barrels to render them impervious to oil. The barrel *J* is placed in the upper chamber and the lid closed tightly. The solution from vat *B* is allowed to flow into *A*, and the faucet *D* is then closed. Steam is then admitted from the pipe entering the bottom of the closed vessel *A*, and, collecting in the top of the vessel, forces the liquid into the chamber in which the cask *J* is placed. When the cask is saturated, the steam is shut off and allowed to flow by faucet *D* into chamber *B*; the liquid sinks from the upper chamber, the lid is lifted, and the cask removed.

Barnum and McNoah's metallic barrel (Fig. 3395) is coated on both sides with lead, and the joints made by riveting and soldering.

There are many patents for compositions, modes, and machinery for thus impregnating, and for coating barrels for this purpose.

Fig. 3395.



Metallic Barrel.

Oil-test. For ascertaining the degree of heat at which the hydrocarbon vapors of petroleum are liable to explode.

That legally employed in Great Britain consists in heating the oil in a porcelain vessel surrounded by a hot-water bath. A wire is placed ¼ inch above the rim of the vessel, and when a thermometer whose bulb is submerged 1½ inches below the surface of the oil indicates the desired heat, say, 90°, a small flame is passed quickly along the wire over the surface of the oil; if no flash is produced, the heat is continued and the test applied at every 3° above this until the flashing-point is reached. The operation is then repeated with a fresh sample of oil, fresh water being used in the outer vessel, the source of heat being removed when a temperature approaching that obtained in the first experiment has been reached. A *fire-test.* See PETROLEUM-TESTER.

Oil-well. The first borings for oil were made at Titusville, Pa., 1859, by Mr. E. L. Drake. Previous to this the petroleum was collected by blankets on the surface of springs and bottled for medicinal use. Nothing was then known of its use for lighting or lubricating. Mr. Drake had great difficulty in obtaining competent drillers, so absurd was deemed the project of searching for a basin of oil beneath the surface. He then gave out that he was boring for a salt-well. He originated the practice of driving a tube to the rock, instead of excavating and cribbing. He drove a tube 32 feet, and then bored 37½ feet. He tubed the well, and obtained by hand-pump 25 barrels per day for two years. It was difficult then to find use for so much. The first refiners were McKeown and Kier of Pittsburgh.

Oil-wells are of various depths, but the mode of sinking them is substantially similar. They vary in depth from 100 to 1,100 feet. After a spot is decided upon, a derrick is built, having four diverging posts planted upon a base of about 12 feet square, and having a hight of 40 feet. So great interest has been felt in the subject, and so frequently has the

Digitized by Google

matter been described in the magazines and journals of the day, that we do not deem it advisable to afford much space to the description of the *modus operandi*. We give a condensation of the description given by a writer in "Harper's Magazine."

The engine-house being erected and the necessary machinery all ready therein, sections of iron pipe, 6 inches in diameter, are driven into the ground by means of a pile-driver until the first layer of rock is reached, which, in most cases, is found at a depth of 35 or 40 feet below the surface of the ground. Great care is taken that this iron pipe is driven plumb. After the rock is reached and the earth within the pipe is removed, a block and tackle is rigged at the top of the derrick, and the drilling-tools, weighing in some cases 900 pounds, are hoisted up and dropped into the driving-pipe down to the rock. A temper-screw is then attached to the top of the drill, by means of a rope, and made fast to the end of a walking-beam, which is a heavy horizontal piece of timber, vibrating on its axis and supported by a Samson-post. The other end of the walking-beam connects with the driving-pulley by means of a crank. The engine drives the pulley, the end of the walking-beam rises and falls, giving the vertical motion to the drill-rod and drill. At intervals, during the process of drilling, a tool called a *reamer* is inserted into the well, its duty being to bring the bore to the proper size and shape. A sand-pump is a metallic tube, from 5 to 10 feet in length, and having a valve in the bottom, opening upwardly. (See SAND-PUMP.) This sand-pump is lowered into the well at intervals, and when it reaches the bottom the valve opens and admits the borings; when the pump is raised, the valve closes and the contents are brought to the surface. After the bore is thus cleaned, the drill is again inserted and the drilling is continued.

In boring a well, a correct journal is kept, showing the different kinds of rock and earth passed through, and the exact points where water-courses, gas, or shows of oil are found.

If a large vein of oil be struck, the well is immediately tubed with 2 or 2½ inch pipe, put together in sections with couplings. The water from veins and from the surface is prevented from running down the well, outside the pipe, by means of a leathern bag filled with flaxseed; the swelling of the seed completely closes all communication between the top and bottom of the well outside the tubing.

If the vein of oil struck prove to be large, and the pressure of gas is sufficient, the oil will flow out without the aid of a pump; but in most cases a pump is required, in which case a copper working-barrel is placed at the bottom of the well and attached to the lower section of the tubing, with a valve at the bottom. The upper valve is connected with a sucker-rod, the end of which is attached to the end of the walking-beam.

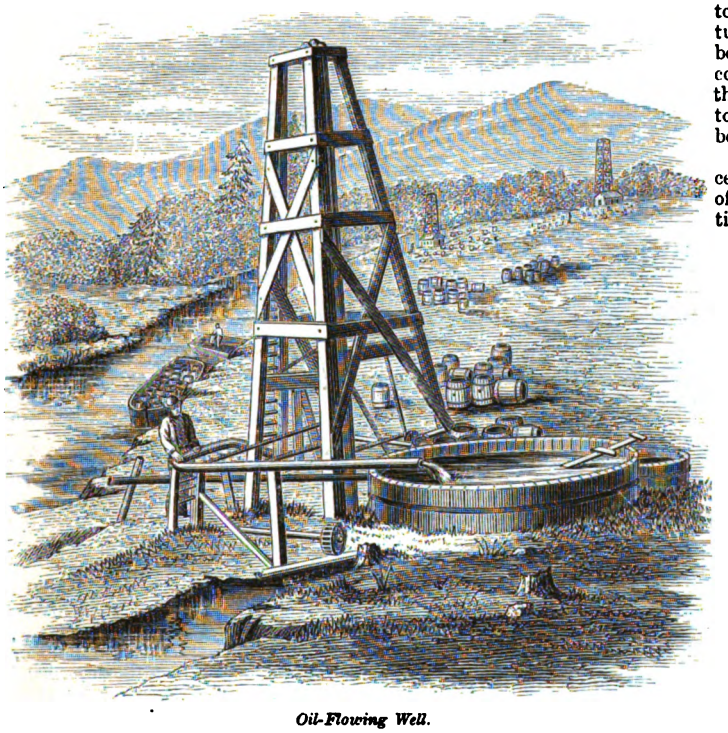
The tanks or tubs to receive the oil are mostly made of wooden staves, but sometimes of boiler-iron, and are placed at some distance from the well; they are connected with it by means of iron pipes attached to the spout of the pump.

It is almost impossible to give the exact cost of sinking and completing a well. Prices vary in different localities, and the cost of drilling ranges from $2 to $3.50 per foot. It may be estimated at an average of $5,500. The tools have been incidentally referred to, and are shown in the accompanying cut. The drill-stem consists of sections of iron rod connected by screw-couplings.

The ordinary drill has a chisel face, but a great deal of ingenuity has been expended on this part of the apparatus. Several varieties are cited under the captions ARTESIAN-WELL; ROCK-DRILL; WELL-BORING, etc.

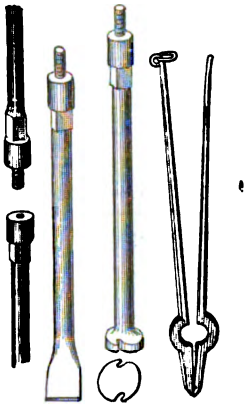
The reamer is introduced into the bore to *true* it; the drill fails to make a smooth hole, and the reamer

Fig. 3396.



Oil-Flowing Well.

Fig. 3397.



Drilling-Tools.

Digitized by Google

is about circular in its form, giving a perfect shape, and fitting the bore to receive the tube.

The pipe-tongs is adapted to grasp the drill-rod or tube while a new hitch is being taken in withdrawing or introducing either.

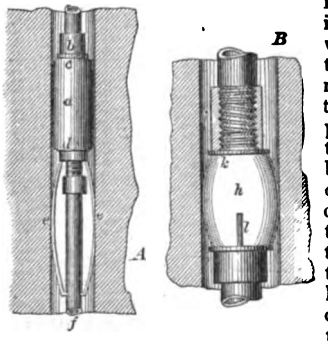
The presence of oil in springs has been noticed from time immemorial, and the rock-oil, Seneca oil, or whatever custom or charlatans have called it, has been famous either as having a sacred character or association, as in the famous wells of the Caspian, or as a liniment. Bitumen, asphate, bituminous shales and rocks, are found in many parts of the world, and the references to the subject are found scattered in the writings of Herodotus, Pliny, and very many others of the writers of antiquity.

"It is said that on digging near the river Ochus [in Bactria] a spring of oil was discovered. It is probable that as certain nitrous, astringent, bituminous, and sulphurous fluids permeate the earth, greasy fluids may be found, but the rarity of their occurrence makes their existence almost doubtful." — STRABO, A. D. 16.

See PETROLEUM.

Oil-well Pack'ing. The usual method of packing oil-wells has been by a *seed-bag*, so called, consisting of a leathern bag filled with flaxseed and placed around the tube, to fill the space between the latter and the sides of the well. The office of the seed-bag is to prevent the water which percolates through upper strata from reaching the bottom of the well, where it would float the oil, and require to be pumped out before the oil would sink to a point where the end of the tube could reach it. It has a farther office in some wells, where a heavy pressure of gas is present, as the said pressure would elevate the oil, perhaps to the surface, were not a way of escape found around the tube, between it and the wall of the well. The seed, becoming saturated with water, swells and forcibly presses the leathern bag against the well-tube and the wall, and the device has proved very effective. It is, however, almost impossible to withdraw it, for the purposes of removing the tubing. The practice has been to "spear" the bag, to allow its contents to escape and permit the leather bag to collapse; but this operation has proved tedious and uncertain, owing to the small limits of the working space and the distance from the surface of the ground. In *A* (Fig. 3398) *a* is an elastic substance surrounding the main tubing, *b* is the ordinary coupling, resting upon the washer *c*, their surfaces ground together and made water-tight; *d* is a loose nut, running upon a screw-thread cut on the main tubing. *e e* are elliptic springs, dovetailed or otherwise fastened to the sides of the loose nut *d*, and partially clasping the tubing at *f*, also pressing the walls of the well at *g*, thereby holding the loose nut firmly and preventing its rotation.

Fig. 3398.



Oil-Well Packing.

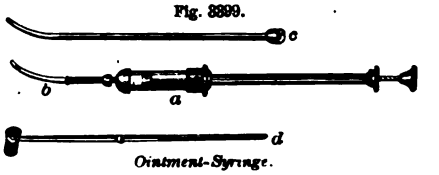
By rotating the tubing from the top of the well while suspended in the tackle, the loose nut *d* is drawn up, expanding the packing and effectually filling the bore of the well.

By rotating the tubing in the other direction, the nut descends and loosens the packing, thereby freeing the tube and allowing it to be withdrawn, if necessary.

Another form is shown at *B*. A cylinder *h* of any elastic substance not affected by oil is placed between two washers about the well-tube. The cylinder is slightly smaller than the bore of the well, and is easily let down therein; but on reaching its position it is compressed by screwing the tube itself down into a long coupling: this action forces the washer *k* against the packing, and squeezes it out so as to fill the passage completely. The packing rests at the bottom on a fixed washer, and has also four ribs *l* to hold it from turning while the tube is screwed up. It will be seen that the thread is not exposed at any point.

Oint'ment-syr'inge. (*Surgical.*) One employed to apply caustic, etc., in the form of ointment, to deep-seated places. The syringe *a* is shown

Fig. 3399.



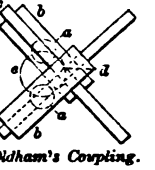
Ointment-Syringe.

with two silver flexible tubes, one *b* for the uterus and the other *c* for the male urethra. The instrument forms a *porte-caustic*.

d is a platinum spoon for melting caustic.

Old'ham's Coup'ling. A sliding coupling for parallel shafts, invented by Oldham. *a a* are the axes of two shafts; *b b*, two cross-heads on their ends; *c c*, bars sliding in grooves in the cross-heads: the bars are fixed together at their midlengths so as to form a cross, the middle point *d* of which revolves upon the dotted circle *e* described on the line of centers, so that its axis of rotation at any instant is at a point in that circle diametrically opposite to *d*. See TRAMMEL.

Fig. 3400.



Oldham's Coupling.

Old-sand. (*Founding.*) The sand forming the floor of the molding-shop to the depth of two or three feet, and filling the deep pits under the cranes. It is generally quite black, is weak and friable, and unfit for the face of any mold. On the other hand, its porous character makes it well suited for filling the flasks over the *facing-sand*.

O'le-ine. The fluid portion of fats and oils after the stearine or more solid portion has been removed.

O'le-o-mar'ga-rin. A substitute for butter. It is prepared by chopping clean animal fat fine, and boiling it; when cool it is churned with pure fresh milk, washed, worked over, salted, and packed for market. It is claimed that this article is scarcely distinguishable from pure butter, and that in consequence of its superior keeping properties it is peculiarly adapted for exportation to warm climates.

O'le-om'e-ter. A species of hydrometer adapted for determining the relative densities of oils.

One form of oleometer, invented by Professor Palmieri of Naples, consists of an electrical apparatus of great delicacy, the object of which is to detect the admixture of other oils with that of the pure olive. The instrument is founded on the fact of the variability in the powers of conduction possessed by the various oils, olive being lowest in the scale. The wires of

Digitized by Google

a battery are brought to a small elongated vessel containing the oil to be examined, and, an electrometer being attached, the degree of conductivity can be read off on a scale. The instrument, it is said, can detect any of the usual adulterants with the utmost nicety. It has also been applied to the detection of woolen or cotton fibers in silk fabrics.

Ol'ive. An escutcheon attached to the strap of a traveling bag or satchel and perforated for the passage of the swiveled stud or button.

Ol'i-ver. A forge-hammer whose handle is attached to an axle and which is worked by a treadle and spring.

It is usually a small lift-hammer, worked by the foot. The hammer-head is about 2½ inches square and 10 inches long, with a swage-tool having a conical crease attached to it, and a corresponding swage is fixed in a square cast-iron anvil-block, about 12 inches square and 6 deep, with one or two round holes for punching, etc. The hammer-handle is about 2 to 2½ feet long, and mounted in a cross-spindle nearly as long, supported in a wooden frame between end-screws, to adjust the groove in the hammer-face to that in the anvil-block. A short arm, 5 or 6 inches long, is attached to the right end of the hammer-axis; and from this arm proceeds a rod to a spring-pole overhead, and also a chain to a treadle a little above the floor of the smithy.

Om-brom'e-ter. A RAIN-GAGE (which see).

Om'ni-bus. 1. (*Glass-making.*) A sheet-iron cover for articles in a *leer* or annealing-arch, in order to protect them from drafts of air.

2. (*Vehicle.*) A large four-wheeled vehicle to carry passengers; the seats being usually arranged on each side, the passengers facing, and the door at the rear.

Established in Paris by a decree of Louis XIV., 1662, and made to hold eight persons. Re-established, 1819. In England in 1829. Amsterdam, 1839.

Om'ni-graph. A PANTOGRAPH (which see).

On'a-ger. An ancient military engine for hurling stones out of a cup-shaped receptacle.

Ooze. A solution of tannin obtained by infusing or boiling oak-bark, sumac, catechu, or other tannin-yielding vegetable.

There are many ways of extracting the ooze: —

1. By cold water.

2. By hot water, steam being conducted to the vats.

3. By boiling, the spent or weak liquor from the pits being employed.

4. By hydrostatic pressure; the ground bark is placed in a strongly bound vessel with a perforated false bottom; a column of water 20 or 30 feet high rests upon the bark and forces the water to filter through the mass.

O'pal-ine. A semi-translucent glass, also known as *fusible porcelain* or *milk-glass.* It is a glass whitened by the addition of phosphate of lime, peroxide of tin, or other ingredients.

O-pal'o-type. (*Photography.*) A picture on milky glass.

O-paque'-disk Re-volv'er. (*Optics.*) A stage disk mounted on a universal joint beneath the object-glass of a microscope, and intended to expose an object at various angles.

Op'ei-o-scope. An instrument for exhibiting the pulsations of sound. It consists of a tube from 1 to 2 inches in diameter, over one end of which is secured a thin membranous substance having a small mirror at its center. When a musical note is emitted into the open end of the tube, which is held so that the beam of light from the mirror may fall upon a white wall or screen, the image will vibrate, the vibrations differing for each tone. By a slight movement of the tube a series of sinuous lines is produced, forming either simple or compound waves according as the note is simple or compound.

O'pen-er. A machine for opening cotton taken from the bales in which it has been closely compacted. Is usually a box or casing with inwardly projecting blunt teeth, and with a screen-like bottom. A drum provided with blunt pins rotates within this casing, opens the cotton, and dirt falls through the grating. See OPENING-MACHINE.

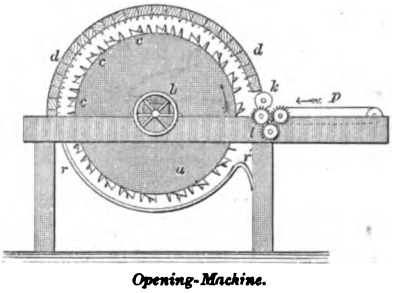
O'pen-ing-bit. A *broach* or *reamer.* A tapering tool with angular sides for widening an aperture.

O'pen-ing-knife. A blunt strong-bladed knife for opening oyster and fruit cans.

O'pen-ing-ma-chine'. A machine for loosening the tussocks of cotton as it comes from the bale, so that the offal and dust may be removed and the fibers parted. The machine has several forms, known as *willy, willower, devil, wolf, beating-machine, cotton-cleaner;* and when associated with a blast of air, as *blowing-machine, scutcher, blower,* and *spreader.*

It consists of a wooden drum *a*, having rows of iron spikes alternating on its circumference with upright iron ridges *c c c*, which prevent the cotton from passing through the machine too rapidly. The top of the drum is covered with a wooden lid *d d*,

Fig. 3401.



Opening-Machine.

consisting of *lags* of wood curved to the shape of the drum, and having similar spikes and ridges.

These lags are capable of being singly moved for the purpose of cleaning or repairing. The lower part of the drum is covered in with the brass wire-gauze *r*, which has an opening at *r'*, through which the cleaned cotton is removed, the dust and impurities falling through the gauze.

The machine is fed from the *feed-cloth p*, upon which the cotton is spread out by hand, and from which it is taken by the grooved nipping-rollers *k l*. The drum is driven by the pulley *b* at the rate of 400 to 450 revolutions per minute. The machine can prepare 1,000 to 1,200 pounds of cotton in a day.

O'pen Link. See OPEN RING.

Open Ring. (*Agriculture.*) A link with one side open, the ends lapping past each other, but not in contact.

Used for coupling the single-trees to the double-tree, and for analogous purposes in agriculture.

Also called *lap-ring,* as the ends lap over each other.

O'pen-sand Mold'ing. (*Founding.*) Heavy beams, foundations, and bed-plates are sometimes molded in the floor of the foundry, without any cope or top part. They are generally filled direct from the furnace. As such castings are never very sound, it is a method not often employed of late years.

Digitized by Google

Op'e-ra-glass. A binocular telescope of the kind invented by Galileo, and with which that philosopher first observed the planetary disks and Jupiter's four moons.

This has a plano-concave or double-concave eye-glass, so that the image is not inverted and little light is lost, thus securing great distinctness. See LENS.

The object-glasses are now made achromatic, and are adjusted simultaneously to the same focus by a milled-headed screw between the two tubes. These are usually made of hard rubber, ivory, papier-maché, or mother-of-pearl, so as to present an ornamental appearance, the use of the instrument being, in consequence of its limited magnifying power and narrow field, principally confined to the interior of buildings.

A larger and superior glass of similar appearance is used in military field service. (See FIELD-GLASS.) It is sometimes provided with a diagonal object-glass having a mirror within the tube at an angle of 45° with its axis, so as to show objects without apparently being directed toward them.

Op'e-ra-hat. A folding hat of felt, silk, or fur.

The *crush;* to fold flatly under the arm.

The *cocked;* the brim cocked up against the side-crown.

See G. Lloyd, English patent 4,900, 1834.
J. T. Tyler, 12,442, 1849.
Gibus, French patent, Fig. 17, Plate 22, Brevets d'Inventions, Vol. III. Loi de '44.

Op'e-ram'e-ter. An attachment to a machine to indicate the number of rotations of a shaft. It consists of a train of gear-wheels and pinions inclosed in a box and connected to or moved by the rotating shaft. A finger on the dial-plate indicates the count.

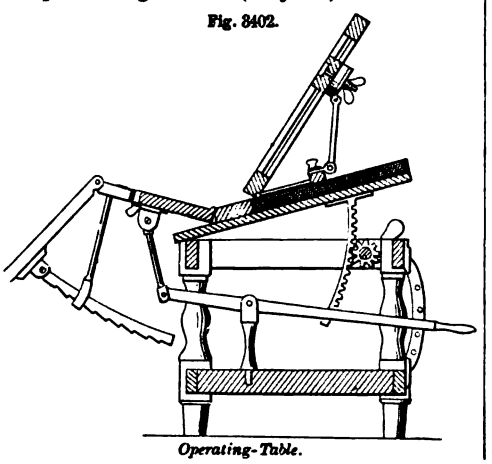
Operameters are used to count the revolutions of a shaft, axle, or wheel, the strokes of a piston, the copies from a printing-press, lengths of sheets from a Foundrinier or other paper-making machine or cloth measuring or printing machine.

A common form is the counter of a printing-press, which has a wheel for units, one for hundreds, and another for thousands. As the *fly* deposits a printed sheet, the unit-wheel moves forward one tooth. The complete revolution of this wheel moves the one of next higher order one tooth, and so on.

The accurate registration of the revolutions of a propeller or paddle-wheel is a matter of much importance to navigators, and many forms of operameters have been tried for this purpose. See REGISTER; ARITHMOMETER; SPEED-GAGE.

Op'er-at'ing-ta'ble. (*Surgical.*) One on which the patient is placed to expose prominently the portion to be operated upon. In the example, the table, back, thigh, and leg supports have individual vertical adjustments to support the patient in any position. The leg pieces have also a lateral adjustment to spread them apart for examinations and amputations, operations on the genitals, in lithotomy, applications of the speculum, etc.

Fig. 3402.



Operating-Table.

Oph'i-cleide. (*Music.*) A wind-instrument of metal, with keys and valves, and made *en suite;* that is, of various sizes and compass. (See HORN, *j*, Fig. 2563.) It is the largest brass wind-instrument of the trumpet species, and forms the bass to that class of instruments. Its compass is 3 octaves.

Ophicleides are the altos and basses of the bugle.

The *bass* ophicleide is written on the F-clef, and its compass is three octaves and one note. They are in two keys, C and B ♭.

The *alto* ophicleides are in F and E ♭; their compass is the same as the bass; they are written on the F-clef, like horns.

The *double-bass* ophicleides are in F and E ♭, a fifth below the bass ophicleides in C and B ♭.

The *bombardon* is a low-pitched instrument without keys and with three cylinders. It differs but little from the ophicleide.

Oph'thal-mo-di-as-tim'e-ter. (*Optics.*) An instrument contrived by Landsberg, a Hanoverian optician, and thus named by him, for adjusting the optical axes of lenses to the axis of vision. It consists of two tubes with adjustable plane glasses, each divided by a central line. On looking through this instrument at a mirror, each eye views its own image, and the glasses are adjusted until the line on the glass as viewed in the mirror is caused to bisect the pupil of the eye. — "Poggendorf Annalen," Vol. CX. p. 435.

Oph'thal-mom'e-ter. 1. (*Surgical.*) An instrument of the nature of compasses for measuring the capacity of the chambers of the eye in anatomical experiments.

2. (*Optics.*) An instrument invented by Helmholtz for ascertaining the true distance at which an object shall be viewed for the accommodation of each eye. It consists of two planes of glass at right angles to each other, and a sight-tube through which they and an object beyond them are viewed. By rotating the glasses on their common axis until the two images formed by reflection from their back surfaces coincide, the proper point of vision is ascertained. — "Poggendorf Ann.," Vol. CXI. p. 415.

Oph-thal'mo-scope. An instrument for inspecting the interior of the eye, invented by Professor H. Helmholtz, and described by him in 1851. He attributed the difficulty experienced in viewing images formed on the retina to the fact that the refractive humors of the eye cause it to be focused at the precise point *c* where the object forming the image is placed. In order to obviate the difficulty thus arising he employed a piece of plate-glass as a mirror, by which the rays from the object are at once both reflected and transmitted.

In the cut, *a* represents a candle, the rays of light from which, falling on the inclined reflector *b*, are thrown through the pupil of the patient's eye *c*, whose retina reflects the image back in the direction whence it was received; the transparent glass plate permitting it to be viewed by the eye *d* of the observer.

By this means the background of the eye is illuminated, enabling the observation of its delicate blood-vessels and tissues.

A great number of forms of this instrument are constructed. That of Dr. Liebrich is probably the simplest. It consists of a concave circular mirror

Digitized by Google

of about 1½ inches diameter and from 6 to 12 inches focus, having a central perforation, behind which is arranged a lens through which the eye, illuminated by the rays from a lamp reflected into it by a mirror, is viewed.

An instrument on the same principle, enabling a person to examine the interior of his own eye, is called an auto-ophthalmoscope. It is shown in the lower portion of the figure.

Dr. Knapp's instrument consists of two centrally perforated plates, connected by a handle, and having between them two disks each with a series of perforations near its periphery in which lenses are inserted, those in the one being convex and in the other concave, so as to form a varied series of magnifiers by turning the disk so as to bring different ones into coincidence over the central opening in the case. One side of the case has an annular concave mirror which reflects light into the eye while it is being examined by a magnifier or the naked

Fig. 3403.

Auto-ophthalmoscope.

eye, through the central opening. One of the openings in each disk is left unfilled, so that only a single lens, or no lens at all, may be used.

Oph-thal'mo-state. An instrument for holding the eye in a fixed position to facilitate operations. Such are the ophthalmostate of Jäger, the fine many-pointed forceps of Graife, etc. They have specific names, such as *fixation-forceps*, *iris-hook*, etc. *Ophthalmostatum*.

Oph'thal-mox-ys'trum. (*Surgical.*) A small brush with barbs like an ear of barley, to scarify the eyelids in cases of ophthalmia.

Op'si-om'e-ter. An instrument for measuring the limits of distinct vision in different individuals, for determining the focal length of lenses suited for remedying imperfect vision.

Lehot's device consists of a white thread placed on a narrow rule covered with black velvet, and having an arrangement for indicating the points at which the thread begins and ceases to be distinctly seen when held in a certain position with respect to the eye. See also OPTOMETER.

Op'ti-cal In'stru-ments. The first ascertained optical fact was probably the propagation of light in straight lines.

Alhazen the Saracen, about A. D. 1100, was the first to determine that the retina is the seat of vision, and that light comes from external objects to the eye. Before his time it had been uniformly taught that rays issued from the eye and impinged upon objects. Euclid treated the subject on that principle.

Alhazen also explained the reason that "we see single when we use both eyes, because of the formation of visual images on symmetrical portions of the two retinas." — DRAPER.

He also wrote on the reflection and refraction of light. Knowing that the air increased in density toward the surface of the earth, he determined that the path of a ray of light through the atmosphere would be curvilinear, and the apparent position of the heavenly bodies an illusion. He also determined the hight of the atmosphere to be nearly 58½ miles. There were philosophers before Torricelli and Galileo.

The discovery of the lens is lost in antiquity, but in its early uses it was a microscope. (See LENS.) For telescopic purposes, a combination of lenses is required, — an objective and an eye-glass. This was invented about 1608 by Lippersheim and by Galileo. The latter turned it on the moon, and saw the shadows of the lunar mountains; on Jupiter, and discovered his satellites; on Saturn, and saw his bulging sides. He supposed the planet to be triple, as his telescope was not of sufficient power to define the ring. He afterward saw the phases of Venus and the spots on the sun. The reflecting telescope was invented in several forms, known as the Gregorian, Newtonian, etc. Then Newton made his discoveries in the reflection, refraction, inflections, and colors of light. Achromatism was discovered by Dolland; afterward polarization of light by double refraction; a century later polarization by reflection, by single refraction; depolarization, and many beautiful phenomena were observed, such as the irised rings, bright and black crosses in crystals, unannealed and compressed glass; then came the discovery that the colors of soap-bubbles were due to the thickness of the film, and this led to ascertaining the length of waves of light. The undulatory theory was suggested in 1664, and was held in abeyance by the supremacy of Newton's preferred material theory; the eye came to be considered as a camera, as described by Da Vinci; later we have reached the kaleidoscope the stereoscope, the photographic camera and processes, the compound and achromatic microscope, which is now working a revolution in anatomy and physiology. Op'ti-cal Square. A reflecting instrument used by surveyors and others for laying off lines at right angles to each other. It consists of a box containing two plane mirrors, set at an angle of 45° with each other, so that the image of an object reflected from one mirror to the other will form an angle of 90° with its true position, indicating the correct direction in which a perpendicular offset to the main line shall be measured. See also SURVEYING-CROSS.

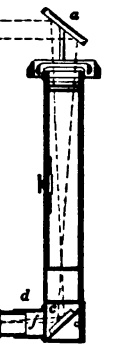
Op'ti-graph. (*Optics.*) A form of camera used for the purpose of copying landscapes. The rays from the object to be drawn are reflected from the plane-mirror *a* through the object-glass of the instrument to the speculum *c*, and thence through the eye-glass *d* to the eye at *e*. At *f* is a piece of parallel faced glass with a small dot on its center exactly in the focus of the eye-glass *d*.

Fig 3405.



Optigraph.

For use, the drawing-board to which the telescope is attached is clamped to a table, so that the surface of the mirror *a* may be nearly parallel to the object, and the pencil placed on any part of the paper where it is desired to commence.

The eye is then placed at the aperture of the eye-tube, and the mirror so inclined as to bring the small dot on *f* on some particular part of the image of the object, and the telescope adjusted to distinct vision. By moving the hand holding the pencil, the dot seen in the field of the telescope is passed over the outlines of the object, which are at the same time traced on the paper by the pencil.

The drawing may be made larger or smaller by varying the distance of the telescope from the paper.

Op-tom'e-ter. An instrument for trying the length of vision in adapting spectacles to the eye.

It consists of a rule to which a sliding upright is attached. This contains the test type, and is first held as near as possible to the cornea and afterward gradually removed until the nearest point of distinct vision is found. In another form, the rule is divided by a longitudinal line, which is viewed through two of several adjacent slits on the slider, when at the proper distance from the eye the line appears to form two intersecting lines. The distance of the apparent point of intersection is marked, indicating the focal distance required for the lens. See also OPSIOMETER.

O'pus. A reticulated masonry. See MASONRY.

Or'a-to-ry. (*Architecture.*) A room in a private house set apart for prayer. It differs from a chapel in not containing an altar, nor can mass be celebrated in it. — CANON.

Or'bit-sweep'er. Invented by Airy, to follow the inclined path of a comet or planet. It resembles a German equatorial, the polar axis of which is of greater length than usual, and which works for some distance at its upper end in a tubular bearing. The declination, or cross-axis, carries at one end a counterbalance, and at the other, not, as in the regular equatorial, a telescope, but a small trunk in which a second and smaller cross-axis turns; to one end of this is attached a counterbalance, and to the other end the telescope. By giving a proper position in rotation to the first cross-axis, any inclination of the second cross-axis to an astronomical meridian may be obtained, and the inclination of the circle in which the telescope will sweep will correspond and may be made to coincide with the definite line on the celes-

Digitized by Google

Orbit-Sweeper.

tial sphere in which the comet is to be sought. — G. CHAMBERS.

Or'der. (*Architecture.*) The different modes of architectural treatment adopted by the ancients in constructing their public edifices and buildings of the higher class are denominated orders. They are usually separated into five, principally distinguished from each other by the proportions of their columns and the kind of capitals employed, but also by the relative proportions and decorative parts of their entablatures, as well as other minor features. They are known as the Doric, Ionic, Corinthian, Tuscan, and Composite.

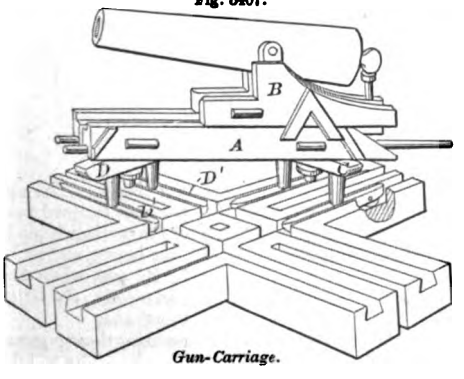
The Tuscan, so called, would, however, seem to be but a debased form of Doric, while the difference between the Corinthian and Composite is but slight, and not in favor of the latter, the copy.

They may be divided into three classes, according to their capitals; those of the Doric and Tuscan consisting simply of an echinus and abacus, the shaft of the Doric column being fluted and having no base, while that of the Tuscan is plain and provided with a base. The capital of the Ionic is distinguished by its volutes, the shaft is fluted and has a base. The Corinthian and Composite capitals are of the foliaged class, having volutes at the angles of the abacus, those of the Composite being the larger, leading to some change in the foliation; the shaft of each is fluted and has a base.

Ord'nance. A class of fire-arms too large to be fired from the person. See CANNON; MORTAR; BATTERY-GUN; HOWITZER; etc. See list under WEAPONS.

When hawks were supplanted by fire-arms, the names of the birds of prey were transferred to the new weapons.

Fig. 3407.

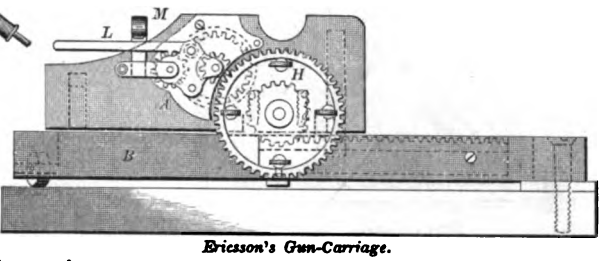


Gun-Carriage.

Mosquet, a sparrow-hawk, became mousquet.
Fançon, a hawk, was a heavy piece of ordnance.
Terzuolo (Ital.), a hawk, was a small pistol, etc.

Fig. 3407 shows a form of timber carriage by which a gun may be trained to all points of the compass, without being pivoted or placed on a circular track. The foundation, or chassis, is composed of timbers framed together in the form of a cross, and having grooves *D' D'* cut in their upper surface. In these grooves the legs of bolsters *C D* run on casters, or slide on greased runners. The bolsters support the bed *A*, on which the carriage *B* slides out and in. The plan of mounting is adapted for use in earthworks and extemporized fortifications.

Fig. 3408.



Ericsson's Gun-Carriage.

Ericsson's gun-carriage, Fig. 3408, is for working guns on shipboard in rough weather, and is designed to check the movement of the carriage instantly, either in its recoil, or when swayed by the motion of the ship. *A* is the gun-carriage, and *B*, a slide-frame on which the carriage runs. *H* is a wheel with cogs on its periphery, which runs the gun out and in by means of gears worked by lever *L*. *M* is a nipper on the side of the carriage, which serves to lock the lever *L* and stop the motion of the gun in case of a lurch of the ship.

Several devices are in use to take up the recoil of guns, by rubber or spiral metallic springs, compressed air, etc.

Some of the gun-carriages devised by Captain Ericsson, and in use on the monitors, are so easy of operation that in case of necessity one man can manipulate a gun weighing 25 tons. See TURRET.

Stevens's mode of operating heavy guns, designed to obtain security for the gunners while loading, is by elevating the breech and depressing the muzzle, until the piece stands at an angle of 30°, or thereabouts. The charge is then inserted through a hole in the deck, if on shipboard, or from below the top of the parapet, if mounted in a fortification *en barbette*. For heavy guns the rammer is worked by steam-power.

This plan of loading was tried on the "Naugatuck," a small iron-clad presented by Mr. Stevens to the United States government. The Parrott gun mounted on this vessel burst while she was engaged with the Confederate forts on James River. The disaster was supposed by some to be the result of the manner of loading, as affording the shot a chance to slip forward after being driven *home*.

Eads's system of working barbette-guns consists in removing the piece bodily below the parapet while loading, and only elevating it to position at the moment of firing.

Fig. 3409 shows a carriage for operating a gun in this manner. The recoil of the gun when fired compresses air in cylinder *a* by the pressure of piston *b*. When the piece is loaded, a valve is opened which allows the restoration of the gun by the expansion of the air.

Digitized by Google

Steam or water pressure may be substituted for that of compressed air. The carriage is trained hor-

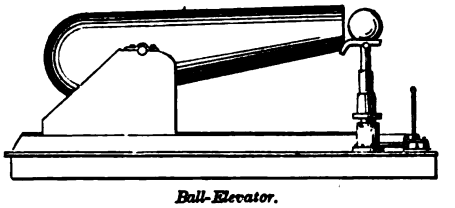
izontally in the usual manner, whether the gun be in a raised or depressed position.

Fig. 3410 is a plan of elevating heavy shot to the gun-muzzle. The ball is placed in a cradle upon a telescopic stem, which is extended by internal steam-

Fig. 3410.



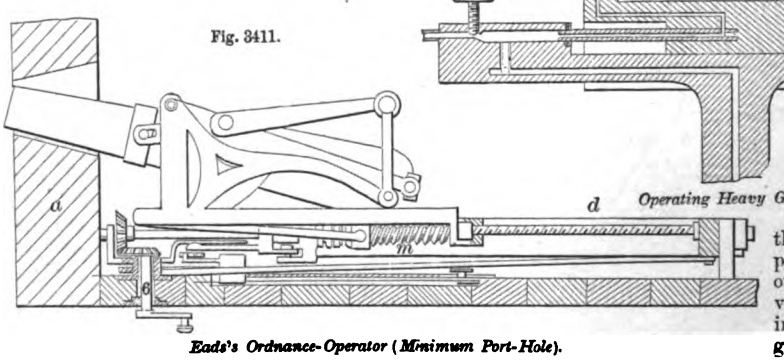
Ball-Elevator.

pressure from below. As it rises, the yoke on the cradle catches below the muzzle of the gun, the front stop is depressed, the pivoted cradle tilted, and the ball rolls into the bore of the gun.

Fig. 3411 is a plan for operating guns, in which the piece may swing about the muzzle, as a pivot, when the gun is in battery, so that a port-hole about the size of the muzzle may be sufficient.

In the figure, the chassis and carriage are moved by revolution of the crank-shaft 6. To elevate or depress the breech, the hollow screw-collar *m* on the shaft *d* is thrown into gear, and by lever connection the breech is swung upward. The collar *m* is left out of gear, and the chassis and carriage swung sidewise, still retaining the muzzle as a pivotal point.

Fig. 3411.

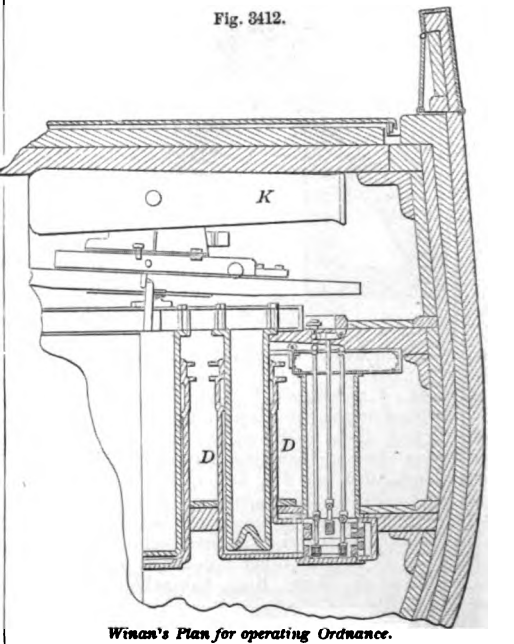


Eads's Ordnance-Operator (Minimum Port-Hole).

a is the shield through which the port-hole is made.

Winan's mode of loading guns on gunboats is illustrated in Fig. 3412. The gun-carriage is formed in two parts, the upper section swiveling upon the lower sections, and is supported on an adjustable

Fig. 3412.

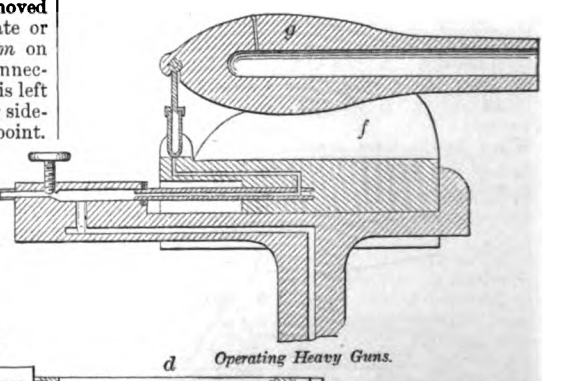


Winan's Plan for operating Ordnance.

chassis, the whole being raised and lowered by steam-power, and also supported on hydrostatic cylinders *D D*, which control the descent of the platform and its carriage. Sliding hatchways are opened and closed by the raising and lowering of the gun-platform. The vessel has no port-holes, and the gun *K* is lifted above the bulwarks when it is to be fired.

Moncrieff's counterpoise-carriage elevates the gun above its parapet by the weight of the front part of

Fig. 3413.



Operating Heavy Guns.

the cheeks. The upper and forward part of the carriage is made very heavy, and rocks in its seat when the gun recoils. See GUN-CARRIAGE.

of gun *g* and carriage *f* is borne by a hydraulic piston, working in a cylinder below. The recoil of carriage *f* expels water from the water-chamber at the rear, and when water is forced back into this chamber by the pumps, the gun is simultaneously run forward and the breech raised to its proper position for firing.

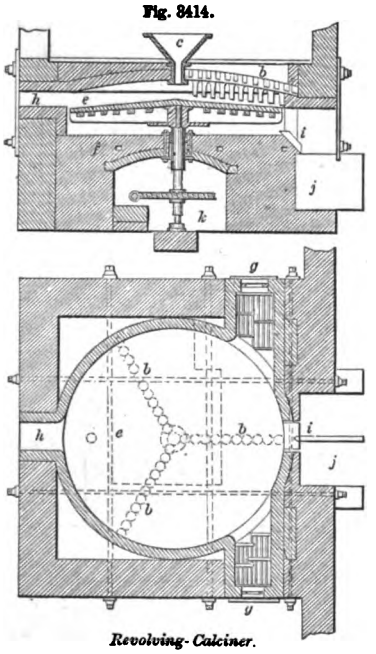
Ore-ap'pa-ra'tus. (*Metallurgy.*) The methods of treating ores are described under various heads, which are assembled under METALLURGY; FURNACE; MILL (which see). The methods are *dry*, *wet*, *hot*, etc. Otherwise classed, they may be *crushers*, *grinders*, *stamps*, *mills*, etc. Or they may be *sorters*, which act by wet or dry processes to save the more valuable from the coarser particles; such are *washers*, *jiggers*, *cradles*, *concentrators*, *separators*. Acting by heat, they may be *blast*, *smelting*, *calcining*, *desulphurizing*, *oxidizing*, *reducing*, *roasting* furnaces. Using quicksilver, they may be *pans*, *barrels*, *amalgamators*, *arrastras*, etc. See under these heads and the lists quoted above.

Ore-cal'cin-ing Fur'nace. A *roasting* furnace for ores. One in which ore is reduced to a friable state; the heat at the same time, as with some iron ores with argentiferous pyrites and many others, driving off certain volatile matters, such as sulphur, carbon, arsenic, phosphorus, antimony, etc.

An *oxidizing* furnace, which reduces the metal in the ore to a metallic calx.

Calcining or roasting furnaces are of various kinds: reverberatory, revolving on horizontal or vertical

Fig. 3414.



Revolving-Calciner.

axes. The furnace shown in Fig. 3414 is used at Constante, Spain, for the roasting of the argentiferous ore, which consists principally of antimonial sulphides of silver disseminated in gangues consisting chiefly of sulphate of baryta, and in combination with arsenic, iron pyrites, galena, and sulphide of copper. The hearth or table *e* is 14 feet in diameter, and makes four revolutions per hour, in which time the furnace consumes about 130 pounds of pine wood. *c* is the hopper through which the charge of ore and salt is fed. *b*, agitator-frames built into the masonry of the arch. The hearth *e* has a slightly conical surface, and is made of fire-brick set on end on a cast-iron shell. The bed *f* is also of refractory clay. The furnaces *g g* are on each side, and the products of combustion, after traversing the flue, pass by the duct *h* to the chimney. After calcination, the ores pass by the spout *i* to the chamber *j*. The stem of the hearth is stepped in a block on the floor of the crypt *k*, being revolved by the wheel and worm. See ROASTING-FURNACE; SILVER-MILL.

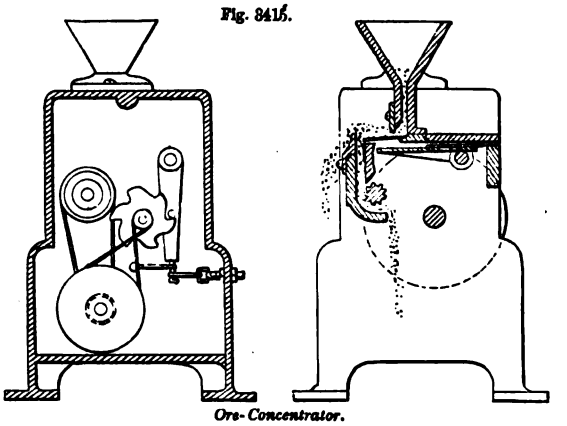
Ore-con'cen-tra'tor. (*Mining.*) A device to sort ores according to richness, or to separate the metallic portions of powdered ores from the gangue.

The processes are two, the *dry* and the *wet*.

The *dry* is illustrated by Krom's. (See CONCENTRATOR.) In this the powdered ore in a thin stratum is exposed in falling to a sheet of air in motion; this blows the particles to a greater or less distance, according to their comparative richness, the quantity of metal in each determining the relative weight. Heavy particles fall down in opposition to the blast; portions less weighty are driven somewhat out of their course and fall over a division board; light parts are blown away as dust. Screens aid in separating.

This device is shown in Fig. 3415, as also in Plate XXXIV. As each projection on the trip-wheel comes in contact with the pin, the lever is thrown back and the bellows carried down. The pin being passed, the rubber spring connecting the lever with another

Fig. 3415.



Ore-Concentrator.

fixed pin carries back the lever and bellows, repeating the operation for every tooth on the wheel.

Plate XXXIV. represents a mill arranged for crushing and concentrating ores by Krom's dry process. The mill is preferably built on a hillside or steep slope, so that the ore may be delivered directly into the third story, where it is fed to the jaw-crusher *a*, by which it is broken into small fragments, and falls on to an inclined screen *b*, where that portion which has been crushed sufficiently fine is separated and conveyed by a chute to the elevator *c*; the coarser portion goes to the first pair of crushing-rolls *d*, where it is farther broken up, and, falling on a second screen *e*, the finer parts are carried through another chute to the elevator, the coarser pieces being transferred to the second crushing-rolls *f*, which complete the crushing, and deliver all the remainder to the elevator.

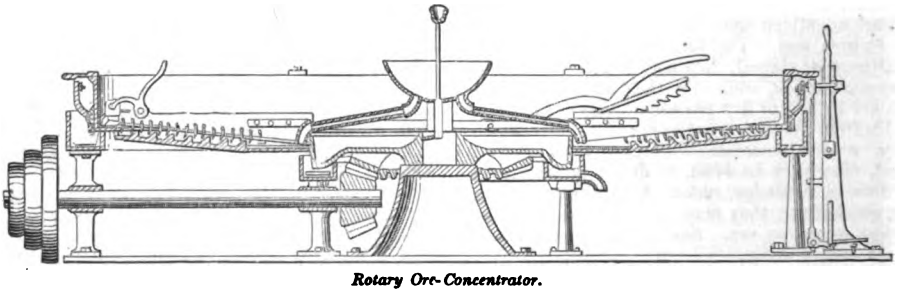
In this way the portions which have been broken sufficiently small are not subjected to the farther action of the rollers, the formation of an excess of

Digitized by Google

fine stuff is prevented, and a less amount, corresponding to the lesser capacity of each pair of rolls, which successively increase in fineness, remains to be treated.

The whole mass of broken ore is conveyed by the elevator to the upper floor of the building and delivered by the chute to the first screen *g*, where such as is still too coarse is conveyed by the pipe *h* back to the rolls to be recrushed, and that which passes the meshes of this screen falls into the second screen *i*; the pieces which fail to pass through the larger end of this screen constitute the first or coarsest

Fig. 3416.



Rotary Ore-Concentrator.

grade of ore for concentration, which flows into one of the bins *l*, three in number, on the third floor. The second grade is obtained from the end of the third screen *k*, while that which passes through its meshes constitutes the third or finest grade; each of these flows to its appropriate bin, whence it is delivered to separators *m*, one for each grade, on the floor below.

The concentrated ore and tailings from the separators are conducted by separate passages to the floor below, the former being received in bags or bins and the latter in cars preparatory to removal.

The dust made in crushing and separating is conducted through pipes leading to the screening-chamber, into the top of which enters the large pipe *n* of the exhaust-fan *o*, which causes a gentle draft from all parts of the building, so that the dust arising from the crushing as well as the screening is all ultimately conveyed to the settling-chamber *p*. The design is only to remove the flowing dust, leaving the heavier particles, which may be susceptible of farther concentration, behind. In the case, however, of gold and silver, the fine dust in the chamber may be preserved for future treatment if of sufficient value; otherwise it may be conducted directly out of the building.

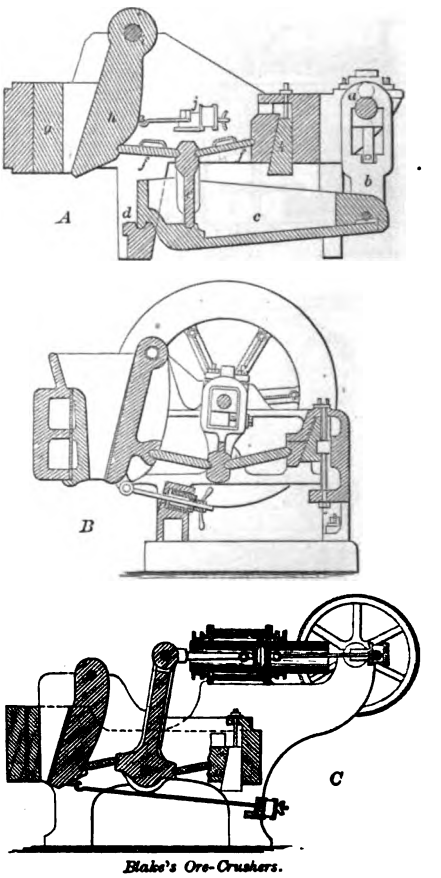
Fig. 3416 is an illustration of the *wet process* of concentrator. The circular, concave, grooved disk has a continuous rotary motion. The ore and water are received at the center and carried by centrifugal force to the periphery of the disk, the heavier particles settling in the riffles. The débris is separated by the current and constant agitation, is carried out by the sluice transversely across the disk to the center, and is discharged through openings into the stationary circular sluice below; the sulphurets are discharged by a plow at the periphery of the disk into another stationary circular sluice below.

In Varney's apparatus, the pulp is passed from the hopper to the pan, which is horizontally oscillated by a cam and recoil spring. By the inclination of the disk forming the floor of the pan, the motion, and the flow of the water, the lighter and heavier particles are assembled on the respective sides of the radial strips which divide the disk into sectional compartments. The trough beyond the periphery of the disk is divided in line with the strips, and has openings on each side of the divisions, which conduct the respective qualities, thus sorted by their relative gravities, by separate channels to their distinct receptacles, the lighter being discharged centrally to the waste-pipe, and the heavier particles of ore being collected in a circular series of boxes placed one below each discharge.

Other varieties might be cited.

Ore-crush'er. A mill for breaking ores into small pieces for farther treatment. Usually a preliminary breaking preparatory to *stamping*.

Fig. 3417.



Blake's Ore-Crushers.

Digitized by Google

Fig. 3417 shows three forms of the Blake ore and stone crusher. In each figure the parts are represented in position as they would be seen by removing one side of the frame *A*. *a* is the crank, *b* is a pitman or connecting rod which operates the lever *c*. This lever has its fulcrum on the frame at *d*. Upon the lever stands a vertical piece *e*, against the top of which the toggles *f f* have their bearings, forming an elbow or toggle-joint. *g* is the fixed jaw against which the stones are crushed. This is bedded in zinc against the end of the frame. *h* is the movable jaw, pivoted at *i* and swinging back and forth by every revolution of the crank. *j* is a rubber spring which opens the jaw, and *k* is a wedge which regulates the degree of closure of the jaw.

The jaws are generally set about 1½ inches apart at the bottom, and the vibration of the moving jaw amounts to about one fourth of an inch at the bottom, being, of course, much less toward the pivot. The full power of the engine is exerted to move the jaw through a very small space when the stone is large, and the force is exerted through a larger space as the pieces grow less in size.

B shows a form of the machine without the lever, the rod on the eccentric shaft being connected directly to the toggle-levers. This is the form of machine most in use in Europe.

C is a machine which has a steam-engine mounted on the frame. A piston-rod from the trunk-cylinder connects with the long arm of a rocking lever which is pivoted between the toggles.

Where large fragments of ore are to be crushed, as often happens in mining, a large crusher is sometimes introduced to break the rock into pieces of moderate size, which are then fed to smaller machines to complete the work. Crushers of this class are used in the Lake Superior copper-mines, and at Freiburg, Saxony.

The jaws of Blake's crushers are usually faced with case-hardened blocks of iron, which can be turned over when worn, and cheaply replaced when this is necessary. The jaws usually have coarse vertical furrows, the elevation on one opposite the depressions of the other, to prevent the passage of long, slim pieces of rock; but plain jaws may be used. See also ORE-MILL.

Ore-fur'nace. (*Metallurgy.*) A furnace for operating upon ores. The term is general, but the actual furnaces have specific names and various constructions, according to the metal, its gangue, the condition, etc. *Blast, calcining, desulphurizing, reducing, roasting, subliming* furnaces may be mentioned, but a list is given under FURNACE (which see). See also METALLURGY.

Ore-hearth. (*Metallurgy.*) A form of reducing-furnace which is without a dome, and known also as a *forge*. See lists under FURNACE; METALLURGY.

Or'e-ide. A factitious gold. See OROIDE. See also ALLOYS.

Ore-mill. A machine for grinding ore, in order that by comminution the metallic portion may be separated from the gangue.

The plate on the next page shows several typical forms of *ore-mills*, known by various technical names, such as *grinders, disintegrators, crushers, stamps*, etc. Other forms not represented, or not as fully shown as desirable in this plate, may be found under the previous figure, the "Blake" crusher, and also under the heads of AMALGAMATOR, ARRASTRA, CHILIAN-MILL, PAN, STAMP, etc.

In Plate XXXV., next page, *A* is a form of mill known as the "Chilian." It rotates on its own axis, and also revolves around the central post, treading upon and grinding the ore in its path. See also CHILIAN-MILL.

B is a form of pulverizer, in which a pestle rolls on its axis and travels in a circular bed whose cross-section approaches the form of the rounded surface of the pestle.

C is a battery of two stamps, operated in the present example by cranks, pneumatic springs in the cylinders above the stamps giving a certain quality to the blow and recoil.

D is a form of crusher in which a heavy roller with circumferential grooves rotates and rolls in a rotating cylinder, the interior of which has corresponding interlocking ridges.

E has an eccentric toothed roller which has a reciprocating rotation.

F has two conical-faced disks, keyed to inclined shafts, having powerful set screws to adjust the width of space between the disks. The ore or stone is fed into a chute, and, falling between the inclined disks, is subjected to pressure as it passes into the gradually contracting space, and is thus crushed.

G has a concentric roller with teeth of varying sizes as the throat narrows, to bite upon the ore, which is gradually comminuted between the jaws as the roller is rocked.

H is a form like some kinds of grinding-mills for stock, excepting that the core and shell revolve in the same direction at different speeds.

I has a series of revolving cylinders with perforations and with interior corrugations; in the middle one of the series are balls. The material is fed through the trunnions and discharged through the holes in the cylinders.

J has a rocking bed and a heavy roller.

In *K* the ore enters the revolving cylinder from the hopper. The heavy inner cylinder rolls in and crushes the ore against the bottom of the outer one, which contains mercury. The discharge-cylinder is attached to the outer cylinder so as to catch any particles of metal that may pass over its edge. A current of water may flow through the apparatus.

L is a Whelpley and Storer's mill. It has a series of beaters *m m* which revolve in a casing and dash to pieces the blocks of copper ore which are placed in the hopper *o* and fed by the corrugated roller. A suction draft from the fan *n* removes the stuff when it is beaten into dust.

M has a wheel with hammers revolving a case with interior corrugations. A fan on the disk face of the wheel drives out the powdered ore.

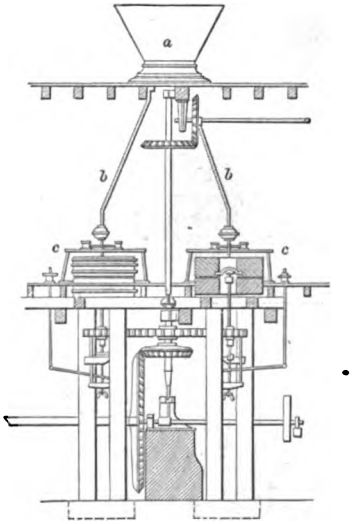
N is Howell and Hannay's machine for crushing quartz, bones, etc., by the percussive force of the rotating projector or by the impingement of the material against the inside of the case.

O is a form of the "Blake" crusher, in which the lower end of the moving jaw rests against the anti-friction roller, and its upper end receives motion by a cam turning in the rectangular opening. The concave faces of the jaws are thus made to roll together with a slight but powerful movement. See also Fig. 3417.

For list of machines and appliances in this line, see METALLURGY; MILLS.

The horizontal mill for grinding silver ores at Constante, Spain, is shown in Fig. 3418. The figure shows two mills, one in section; each has buhr stones, and is fed from a hopper *a* with ore ground so as to pass through a sieve of a gage of 100 openings to the square inch. Pipes *b b* lead the ore to the stones *c c*, which revolve in casings. The runners are suspended by balance-rynds upon the cock-heads of spindles, as in grain-mills, and are driven by a system of gearing below, which needs no particular description.

Fig. 3418.



Horizontal Ore-Mill (Constante, Spain).

Fig. 3419 is also a horizontal mill having a pair

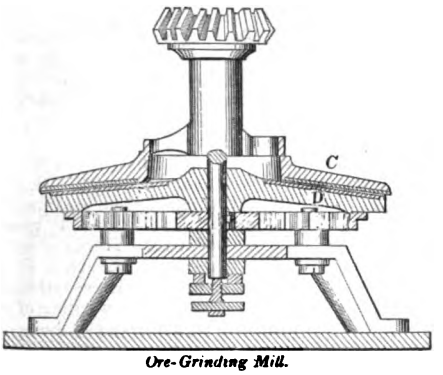
Fig. 3419.



Ore-Grinding Mill.

of slightly conical disks *C D* revolving in opposite directions.

Pliny says that "the ore is first broken up and washed, then roasted and ground to a fine powder." This was placed in a reducing-furnace to expel volatile metals, and the remainder was again ground and farther reduced in crucibles. He speaks also of breaking-machines used for crushing the silex as being shod with pieces of iron weighing 150 pounds. These were probably iron-shod stamps. See GOLD.

"Whate'er is excellent in art proceeds
From labor and endurance: deep the oak
Must sink in stubborn earth its roots obscure,
That hopes to lift its branches to the skies:
Gold cannot gold appear, until man's toil
Discloses wide the mountain's hidden ribs,
And digs the dusky ore, and breaks and grinds
Its gritty parts, and laves in limpid streams,
With oft-repeated toil, and oft in fire
The metal purifies: with the fatigue,
And tedious process of its painful works,
The lusty sicken, and the feeble die."

DYER, *The Fleece*, 1757.

Ore-roast'ing Fur'nace. (*Metallurgy.*) One for heating powdered ores to drive off sulphur, arsenic, and other ingredients amenable to this treatment, and prepare the mineral for farther operations, by which the metallic portions are separated from the gangue.

Roasting-furnaces are of various kinds, some adapted to special metals. See COPPER FURNACE; ROASTING-FURNACE, etc., and list under FURNACE.

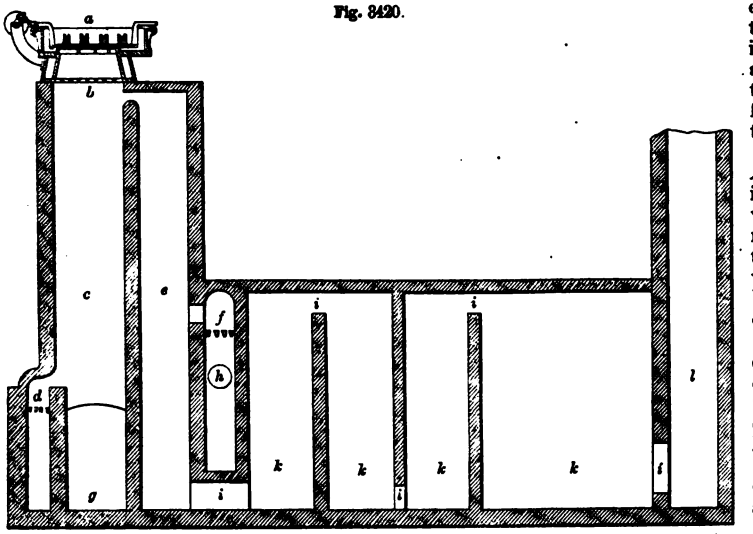
Others are known by their peculiar purpose, as *desulphurizing*, *calcining*, *oxidizing*, *reducing* furnaces, etc.

Others are known by their construction, as *reverberatory*, *horizontal*, *rotary*, *shaft* furnaces, etc.

The above are considered under their respective heads.

Fig. 3420 is a view of the Stetefeldt ore-roasting furnace, so much used in the silver districts, and shown under SILVER MILL in its relation and position to the *crusher*, *stamps*, and *amalgamator*. It is of the class known as a *shaft-furnace*, in which the finely powdered ore is mixed with certain chemical re-agents and dropped into the flame, which passes up the chimney. In the case, for instance, of operating upon the sulphides of silver mined in Utah, the ore which has been broken in the *crusher*, and reduced to powder by the stamps, is mixed in the latter with a certain percentage of salt, and then conveyed to the top of the furnace, where it is distributed by the feeder *a* in a shower of fine dust by the sieve *b*; falling down the shaft *c*, it is exposed to the full effect of the flames and heat rising from the furnace *d*, for which the shaft *c* forms a chimney. A double decomposition takes place in the shaft, the chlorine leaving the sodium and entering into combination with the silver to form chloride of silver, while the sulphur parts company with the silver and unites with the soda to form sulphate of soda, which is readily dissolved and runs away in the tailings. The heat of furnace *d* passes up the shaft *c* by way of an arch into descending flue *e*, where any metallic dust which is carried over is subjected to the action of the flame from the second furnace *f*; *h* is the air-opening for the supply of air to furnace *f*. The chambers *k k k*, connected by arches *i i i*, are for the collection of metallic dust, and are cleaned out from time to time. *l* is the chimney. The main body of the ore from the feeder *a* collects at the bottom of the shaft *c*, where it remains in a hot bed, and is removed at intervals to the damping-floor and the amalgamator. See SILVER-MILL.

Fig. 3420.



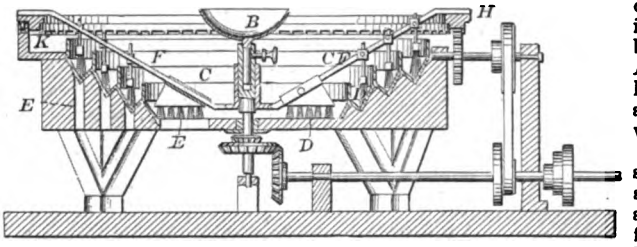
Stetefeldt Furnace.

Ore-sep'a-ra'tor. A general term which includes machines of various kinds for separating metallic ores from the gangue, after pulverization. They may be classed into wet and dry. Of the former are the *washers*, *frames*, *cradles*, *jigging-machines*, etc. Of the latter are *ore-concentrators*, etc. See also list under METALLURGY.

In Fig. 3421, the crushed material descending in regulated quantities from a vertical spout impinges on the rapidly rotating disk *B*, from which it is thrown off by centrifugal force, being at the same time sorted according to size and gravity,

Digitized by Google

Fig. 3421.

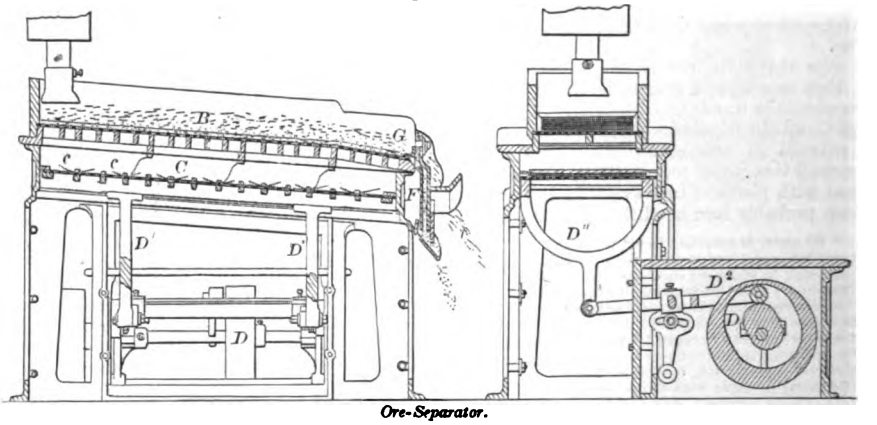


Ore-Separator.

the lighter portions falling farther from, and the heavier nearer to, the disk; the different sizes are received in the various grooves *C C* of the circular trough, and are swept into their appropriate chutes by brushes *D D E* attached to arms *F F*, which are fastened to a circular toothed rack *K H* rotated by a pinion driven by belt connection with the main shaft.

In Fig. 3422, the broken ore descends from a spout on to the inclined sieve *B*, through the meshes of which an upward current of air is passed from the bellows *C*. This is operated by the cam-wheel *D*, yokes *D' D' D''*, and levers D^2; these latter are adjustable on the wheel to regulate the working of the bellows, which is provided with valves *c c*, the open-

Fig. 3422.



Ore-Separator.

ings of which may be varied to control the force of the blast, which requires to be stronger near the lower end, where the coarser particles collect. The various sizes are discharged through different chutes *F G*.

Ore-smelt'ing Fur'nace. One for reducing metal from its ores. See BLAST-FURNACE; IRON; SMELTING-FURNACE. See also lists under FURNACE; METALLURGY.

Ore-stamp. A means of crushing ore by shod beams vertically reciprocated. See STAMP-MILL.

Ore-wash'er. (*Metallurgy.*) A means of separating metal from ore after the latter has been reduced to powder. The slimes or metallic mud are agitated in *jiggers*, flowed over *frames* or *riffles*, exposed to a stream of water in *concentrators*, or otherwise treated with water so as to float off the lighter and less valuable portions, leaving the metal behind. See list of machines and processes under METALLURGY.

Gold is separated from broken quartz or from sand by similar methods. See GOLD-WASHER; GOLD-MINING.

Or'gan. (*Music.*) A musical instrument in which the notes are produced by pipes of different lengths, shapes, and materials, supplied with air by bellows and operated by keys which admit or cut off the supply.

The dimension of the instrument is designated by the number of feet of length that its largest pipe measures, forming the lowest note of the key-board. Thus, we speak of an organ of 32, 16, or 8 feet. An instrument which possesses *open flutes* of 32, 16, 8, and 4 feet, and a *principal* an octave above the latter, has a compass of 8 octaves. See MUSICAL INSTRUMENTS, Fig. 3263.

Large organs sometimes have five key-boards, one above another.

The first, nearest to the organist, is that of the *choir* organ.

The second, that of the *great* organ.

The third, the *bombarde* key-board.

The fourth, the *recitative* key-board.

The fifth, the *echo* key-board.

Below these is the *pedal key-board*, played by the feet. The music of the organ is sometimes written on three lines, the two upper ones for the hands and the under one for the pedal key-board.

The *organ* of Jubal (Gen. iv. 21), 3875 B. C., may be supposed to have been a mouth-organ or Pandean pipes. His name is associated with the invention of the harp and the organ, — stringed and wind instruments, — and the same connection of musical instruments is maintained in the Book of Job and the Psalms. In the latter case, the trumpet, harp (*of two kinds*), timbrel (*tambourine*), organ, and cymbal are referred to. The Greek word ὄργανον, from which our word "organ" is derived, denoted an instrument of any kind, but was more particularly applied to musical instruments. According to Vitruvius, *organum* was a term applied to any instrument requiring skill in its use, while the *machina* merely required animal force for its operation.

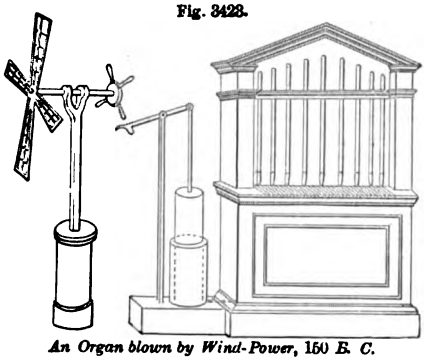
The mouth-organ, or Pandean pipes, was expanded into an instrument resembling the bagpipes, in which the air for supplying the pipes producing the musical tones was blown by the performer.

In the "Spiritalia" of Hero of Alexandria, who

Digitized by Google

flourished 150 B. C., we find a description of an organ blown by the agency of a wind-mill which works the piston of the air-pump. Its invention is, perhaps, to be credited to Ctesibus of Alexandria, though it is likely that it was the result of the gradual improvement

Fig. 3423.



An Organ blown by Wind-Power, 150 B. C.

by various parties through the centuries. The reconstruction of it given in Fig. 3423 is by Woodcroft, from the text of the "Spiritalia." The descriptions of it by Athenæus, Vitruvius, and Claudian render it certain that the pipes were musical, and blown by the force of water, instead of expansible air-bellows.

Athenæus thus describes it: —

"And Alcides said: 'But this engine, the hydraulic organ, whether you choose to class it among stringed instruments or among wind instruments, is the invention of a fellow-countryman of mine, an Alexandrian, a barber by trade, and his name is Ctesibus.'

"And Aristocles reports this in his book on 'Choruses,' saying: 'The question is asked, whether the hydraulic organ is a stringed or a wind instrument. Now, Aristoxenus did not feel sure on this point; but it is said that Plato showed a certain notion of the invention, making a nightly clock like the hydraulic organ, being very like an enormous hour-glass, which, indeed, it resembles. It cannot, therefore, be considered a stringed instrument, and one to be played by touching. But perhaps it may be called a wind instrument, because the organ is inflated by the water; for the pipes are plunged down into the water, and when the water is agitated by a youth, as the axles penetrate through the whole organ, the pipes are inflated and emit a gentle and agreeable sound. And this organ is like a round altar, and they say was invented by Ctesibus the barber, who dwelt at that time in the territory of Aspendor, in the reign of the second Ptolemy, surnamed Euergetes, and they say that he was a very eminent man, and learnt a good deal from his wife Thais. Trypho, in his dissertation upon flutes and organs, says that Ctesibus, the mechanician, wrote a book about the hydraulic.'" — From the "Deipnosophists," by Athenæus, A. D. 220.

A fuller description of an organ of this kind may be found in Vitruvius. An organ with pipes of varying length, and apparently about 10 feet high, is shown on a coin of the gentle Emperor Nero. He was much addicted to music, and is supposed to have also soothed his mind by the bagpipes. A Greek epigram in the Anthologia, attributed to the Emperor Julian, A. D. 364, has the following description: "I see reeds of a new species, the growth of another and a brazen soil, agitated by a blast rushing from a leathern cavern beneath their roots and producing melodious sounds, as the keys dance under the skillful fingering of a robust performer." The origin of the bellows organ would thus seem to have been known to the Greeks of the Eastern Empire.

Fig. 3424 shows several old methods adopted for supplying wind to the organ; the arrangement of the keys and the manner of manipulating them are also illustrated.

A is a representation by Father Kircher of a very primitive form of Hebrew organ, the "Macraphe d'Aruchin." In this, as in other of the earlier organs, a leathern bag served the purpose of the wind-chest.

B is copied from the sculptures on an obelisk at Constantinople, erected by Theodosius, who died A. D. 395

C is a pneumatic organ of the tenth century; it is taken from an ancient psalter in the library of Trinity College, Cambridge.

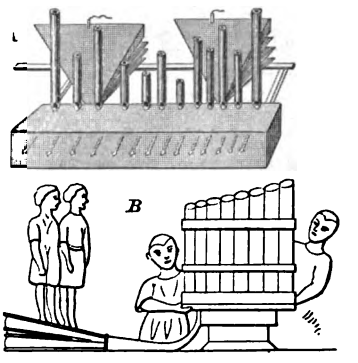
D, from Gori's "Thesaurus Diptychorum," is said to have been taken from a manuscript of the time of Charlemagne. It represents King David seated on his throne, his scepter in one hand and a lyre in the other, on which he appears to be playing, accompanied by several instruments, including the organ.

E is from an engraving in the "Theorca Musica" of Franchinus Gaffurius, printed at Milan, 1492.

F, from the "Theatrum Instrumentorum" of Prætorius, 1620, shows the ancient method of blowing. On each bellows is fixed a wooden shoe; the men who work them hold on to a horizontal bar, and, inserting their feet into a pair of the shoes, alternately raise one and depress the other.

G is what was formerly known as the "positive," in contradistinction to the "portative" organ. The lat-

Fig. 3424.



Old-Time Organs.

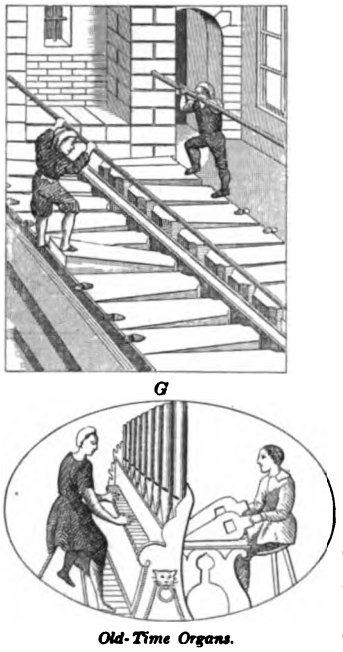
Fig. 3425.



Old-Time Organs.

ter, as its name implies, was portable, being carried in processions by one person and played by another; it was also called the "regal" or "rigol." The former was fixed in position, and, when carried in a procession, it and its stand were placed on a car. An organ of this kind was afterward placed before the great organ in churches, the two constituting a single instrument, the "positive" being the origin of what has since been designated the *choir* organ.

The organ is said to have been applied to religious services in churches in 657, and first used in the Western churches in 658 by Pope Vitalianus; though they were, according to Julianus, a Spanish bishop, commonly used in Spain 200 years previous to this date.

In 757, the Emperor Constantine IV. presented an organ to King Pepin of France; and one, the work of a Saracen artist, was presented to his son Charlemagne by Haroun al Raschid; and, in 812, Louis le Débonnair built one on the Greek model at Aquisgrana, the modern Aix-la-Chapelle.

Several German organs were placed in Italian churches by John VIII., 872–882.

About 951, the abbey of Malmesbury and the cathedral of Winchester in England were provided with organs. At this time and for two centuries later, the compass was small, usually from 9 to 11 notes, the brass pipes harsh in tone and the machinery clumsy; the keys being 4 or 5 inches broad, and struck by the fist.

Gerbert of Auvergne, in his school at Rheims, had an organ played by steam. He was afterward made Pope by the Emperor Otho III., assuming the name of Sylvester II. He and his patron were poisoned by Italian intriguers about 1002. Gerbert introduced the Arabic numerals into Europe.

The organ of Winchester, probably placed there by St. Dunstan, had 26 pairs of bellows, 400 pipes, and required 70 men to work it.

The *key-board* is distinctly described at the close of the eleventh century. At this time a number of small bellows, 20 or more, were used, worked by men who held to a horizontal rail and operated the bellows with their feet, as at *F*, Fig. 3425. It is said that half-notes were invented at Venice in the twelfth century, but the earliest authentic example of their introduction was in the Halberstadt organ, built about 1360. The invention of the pedal is claimed for Bernhard, a German organist to the doge of Venice, 1470–80. He probably made some improvement in that appendage, but it appears to have been in use nearly a century previous.

The organ of Nuremberg had pipes from 16 to 32 feet long, A. D. 1468.

In 1596, the organ of Breslau had most of the now known stops.

It would seem that up to the fifteenth century organs were generally constructed by the monks, but about this period organ-builders by profession were to be found both in England and on the Continent. The earliest recorded in England was William Wotton, who, in 1587, agreed to make a pair of organs for Merton College, Oxford, for the sum of £28.

The German and Dutch builders appear to have taken the lead, and we find that, notwithstanding the strenuous opposition of Zuinglius and some of the early reformers, the German churches were, during the sixteenth century, generally provided with organs. During this century, the German builders introduced the *register* and the stopped pipe. The key-board also was extended to four octaves.

England, also, was well provided with artists of this class, and possessed some fine instruments.

In 1634, we are informed that the organ in the cathedral of Durham cost £1,000. Those of York, Litchfield, Hereford, Bristol, and other cathedral towns were also noted.

During the civil war, the Puritans, particularly the parliamentary soldiers, destroyed many fine organs, breaking them in pieces and selling the pipes for old metal. Few or none being built during this period, the art became almost forgotten in England, so that Pepys records, under date of July 8, 1660: "To White-Hall Chapel, where I got in with ease by going before the Lord Chancellor with Mr. Kipps. Here I heard very good musique, the first time that I ever remember to have heard the *organs* and singing men in surplices in my life."

The class of native organ-builders having become almost extinct, inducements were offered to foreigners to settle in England. Prominent among these was Schmidt, generally known as Father Smith, who built the instrument referred to by Pepys. Among the instruments of this period was the organ of St. Paul's Cathedral, noted as being the source of much tribulation to Sir Christopher Wren, who considered that the harmony of his designs was spoiled by the "box of whistles." This instrument was nearly 30 feet high, 18 wide, and 8 deep.

About 1680, the *barrel-organ* used by itinerant musicians was introduced.

The early builders were fond of employing *outré* materials in their organs, and of decorating them with precious metals and stones, or with grotesque carvings; animals, birds, and angelic figures moved by mechanism were also introduced, the latter playing on the trumpet or beating big drums.

The old organ at Lynn, in Norfolk, had a figure of King David playing on the harp and larger than life, cut from the solid wood; likewise several moving figures, which beat time, etc.

We are told that the Emperor Theophilus, 829–41, had "two great gilded organs, embellished with precious stones and golden trees, on which a variety of little birds sat and sung, the wind being conveyed to them by concealed tubes."

The Duke of Mantua had an organ in which the pipes and other parts were made of alabaster. A pair of organs at Venice were made all of glass, and of the eight in the convent of the Escurial, near Madrid, one is said to be made of solid silver.

The devices required in order to make a pipe sound or *speak* are: the bellows, for supplying condensed air; a channel, for conducting it to the pipe; a valve or other contrivance, for admitting and cutting it off; and a lever, for opening and closing the valve.

The pipes are of two descriptions: the *mouth* or *flute* pipe

Digitized by Google

(technically called *flue*-pipe) and the *reed*-pipe, which are each further divided into several varieties.

Mouth-pipes, so called from having a mouth and lips similar to those of the flageolet, are either of wood or metal. The latter are those observable at the front of the organ case, and are cylindrical in cross section. The wooden pipes are rectangular in section, the sides being in the proportion of 5 to 4; the interior is usually sized with glue. The upper end is open, or is closed by a tompion made air-tight by a leather covering. The other end is closed by a block to which three of the sides are glued, a narrow aperture being formed between the block and the front side, by beveling this side so as to have its sharp edge on the interior; this is called the *upper lip* or *wind-cutter*.

Another block is arranged so as to leave a narrow space between it and the block. The hollow cylinder, through which air from the bellows is supplied, is let into this block.

A mahogany cap, hollowed out on the inner side so as to leave the aperture free, is fastened to the front of the pipe below the mouth. The aperture between the cap and the block, called the *plate-of-wind*, admits the compressed air from the bellows in a thin stream, which, being forced against the mouthpiece or wind-cutter, produces a musical note determined in pitch by the length of the column of air set in motion. In order to *voice* the pipe, — that is, improve the tone, — the edge of the block opposite the upper lip is slightly pared away and serrated so as to divide the plate of wind and direct it against the inner edge of the lip.

The pitch of a note depends on the length of the pipe (see PIPE), while the tone or *timbre* depends on its diameter, its shape, or on the kind of wood employed; that yielded by pipes of hard woods, as mahogany, being more clear, while the softer woods yield a mellower sound.

The *chimney-top* pipe has a small open tube in the top-plate for the purpose of sharpening the note: a similar effect is sometimes produced by a hole in the tompion.

Metallic mouth-pipes are made conical at their lower termination, and where this cone and the cylindrical portion unite is an aperture occupied by a thick plate of soft metal, called the *languette*, nearly closing the tube, but leaving a small opening for the wind-plate, formed with the upper lip.

The thickness of the stream of air admitted to the pipe may be diminished by turning down a projecting exterior lip on the plate.

The *reed-pipe* is closed near the bottom by a solid plug, having apertures for the passage of the reed and its adjusting wire. The *reed* is a cylindrical or slightly tapering tube of brass, having a narrow longitudinal slit in front, covered by a thin plate of metal called the *tongue*, which is made fast to the reed at its upper part, but is free at the lower end. The back part of the reed is cut off slanting at its lower termination, over which a piece of metal is soldered.

The *pitch* of the reed-pipe depends on the length of the tongue, which is adjusted by means of the *tuning-wire* above mentioned; the *quality* of tone depends on the pipe.

In the free reed of Grenié, invented many years ago, the tongue, instead of battering against the side of the reed, vibrates within the opening, producing a more uniform, sweet, and harmonious tone.

It also admits of the musical effects called *crescendo* and *diminuendo*, by varying the pressure of the air. The air escapes through tubes in the form of an inverted cone, whose upper portion is hemispherical and slit.

A *stop* consists of a series of pipes agreeing in quality of tone, or timbre, but differing in pitch. When any particular stop is drawn the keys will play on the corresponding set of pipes.

The stops are designated by figures or by words intended to be descriptive of the quality of sound, as *flute*, *oboe*, *vox humana*, etc. See STOP.

Two or more key-boards are required to enable the performer to produce all the notes in an organ of more than one stop.

In a large organ the different series of stops are so arranged as to form three or four separate instruments, each having its own set of keys, wind-trunk, wind-chest, sound-board, etc. These have been distinguished by different names, as the *great-organ*, the *choir-organ*, and the *swell;* also the *pedal-organ*, or *foot-keys*, which act on the larger pipes.

Couplers are also brought into action at will, which connect the keys on different banks so as to make them act together when one is played. The effects are also varied by *tremulo* and *swell*, which give respectively quavering and rising and falling force of sound.

The feet of the pipes are inserted in the *upper* or *stock* boards, above the bearers and supported on *racks*, — thin boards mounted on pillars.

The pipes of the larger stops, however, take up so much space that they cannot be placed immediately over their proper groove, but they may be placed in any convenient position, even outside of the case, and air conveyed to them by means of grooves cut in the upper boards and covered with parchment, forming closed channels.

The key movement, in its simplest form, comprises: the *key*, a pivoted lever, which, being pressed down at one end causes the other end to raise the *sticker*, a small wooden rod depending from the end of a second lever above, which is thus depressed at its opposite end, drawing down the *pull-wire* and opening the *valve*.

This arrangement is, however, only applicable in case each key is opposite its own proper valve, a condition which can only apply in few instances. This difficulty is remedied by introducing a series of rollers above the secondary levers, whose ends are connected by wires with arms on the sides of the rollers; the other ends of these, on the same side, have also arms to which the wires controlling the valves are attached.

The foregoing description will give an idea of the general principles governing the construction of organs, though there are many mechanical details and improvements introduced into modern construction to which we have not space to refer.

The *bellows* communicate with the *wind-chests*, which act as reservoirs and distribute the air to the different *pipes*, as the finger or foot *keys* are pressed down. The pressure of air is regulated by a weight on the upper part of the reservoir, usually about 15 pounds to the square foot. The different parts of the organ are now commonly supplied with air under different pressures, separate bellows being used for each pressure.

The *wind-chest* is an air-tight box communicating above with the *sound-board*, an oblong frame or box of wood divided by parallel strips into channels or compartments completely separated from each other. Holes corresponding with the number of ranks of pipes are bored through the upper part of the sound-board into each channel. Its lower side is covered with parchment or leather, except on that part where the channels communicate with the wind-chest and are closed by clack-valves opened by means of *pull down* wires operated by lever connection with the keys and brought back by a spring. On the upper side of the sound-board, at right angles to these channels, a set of grooves, corresponding in number to the number of stops, is formed by screwing down thin pieces of hard wood, termed *bearers*. These communicate through holes with each of the channels below, and each has a register or slide, a little thinner than the bearers, but exactly fitting the groove in length and width. The slides are pierced with holes corresponding in number and size with those of the sound-board, so that by drawing out or pushing in any particular slide, it is caused to open or close the holes in the sound-board, and supply or cut off the air from the range of pipes above it.

In organs of the largest class as formerly constructed the operation of the keys was a work requiring, in addition to musical skill, a large amount of hard bodily labor. It is said that the performer on the great Haarlem organ was obliged to strip preparatory to commencing his work, and retired covered with perspiration at the end of the hour's performance. This is one of the largest instruments in Europe, having 60 stops and 8,000 pipes. One at Seville has 5,300 pipes. The expenditure of wind varying greatly, according to the series of notes produced, the tension of the air supply was very different at different times, causing a variation in the purity of the tone and difficulty in opening the valves when under high pressure. These difficulties were remedied by the *pneumatic* lever of Barker, in which small subsidiary bellows operated by the movement of the key are employed to depress the wires by which the valves are opened.

Where an extraordinarily large supply of air is required, it may be furnished by blowers or bellows operated by hydraulic or steam power. Fig. 3426 illustrates the blowing-engine employed for the great organ at the Hall of Arts, South Kensington, London, England. It is a vertical beam-engine, having two steam cylinders of 7 inches diameter and 24 inches stroke, and two blowing cylinders of 24 inches diameter and 24 inches stroke. Its principal duty is to compress and attenuate air for blowing and for mechanical purposes, such as opening and closing the stops. The valves of the blowing cylinder are of india-rubber. The upward stroke exhausts the air from vacuum receivers, to which it is connected by zinc piping, and the down stroke exhausts the pressure receivers to which it is similarly connected. In addition to the ordinary governor, it has two throttle-valves connected respectively with the pressure and vacuum receivers, so that when the former is filled with air at 1½ pounds pressure above, and the latter with air at 1½ pounds pressure below, that of the atmosphere, both throttles are closed and the engine stops, thus regulating the supply according to the ever-varying requirements of the organ.

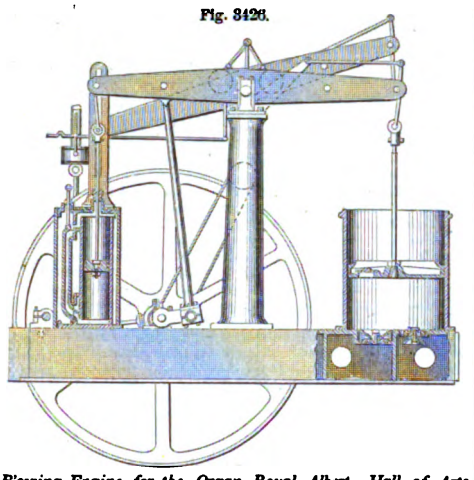
Fig. 3426.



Blowing-Engine for the Organ Royal Albert, Hall of Arts and Sciences, South Kensington, London.

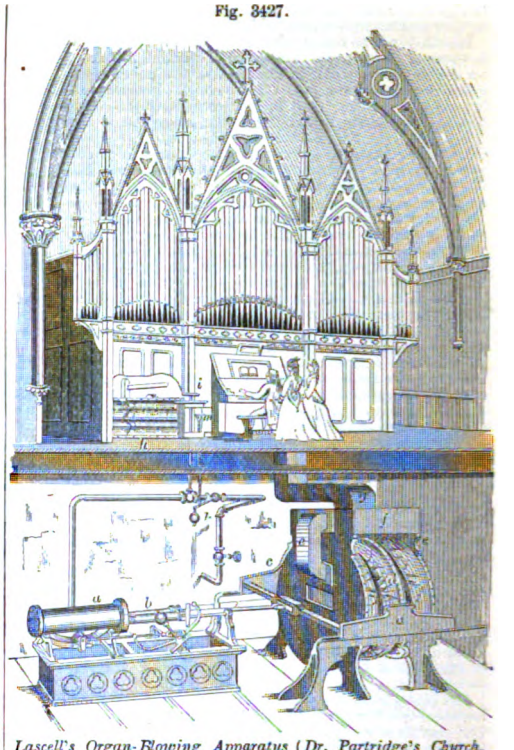
A horizontal engine of 13-horse power, driving a crank to which six large bellows are connected, furnishes compressed air to the reservoirs which supply the pipes.

This giant organ is 60 feet wide and 70 feet high; the four center pipes, which are over 40 feet long, weighing nearly a ton each. The instrument was erected by Mr. H. Willis, and, according to the "English Mechanic," is the finest in the world, having five claviers (four manuals, extending from C C to C in altissimo, and one pedal from C C C to G). The pedal-organ consists of 21 stops; the first manual clavier, or choir-organ, including the echo-organ, comprises 20 stops, all the pipes in which are of metal. The second clavier, or great-organ, contains 25 stops, only two of which have wooden pipes in the bass notes. The third clavier, or swell-organ, comprises 25 stops, and these are all, with the exception of the basses of two stops, of metal. The fourth clavier, or solo-organ, has 20 stops, making in all 111 stops; then there are 14 couplers and 32 combinations. The total number of pipes is close upon 9,000, and these range from 30 inches diameter down to the size of a straw, and from 40 feet in length down to 6 inches.

Fig. 3427 illustrates an organ provided with the hydraulic blowing apparatus designed by G. W. Lascell, Brooklyn, N. Y. *a* is the cylinder, the piston-rod of which *b* is attached to the cross-head of a reciprocating frame *c*, by which the movable diaphragm *d* of the double-acting bellows is operated, alternately forcing the air through the pipes *e e* into the wind-chest *f*, from which it is distributed by the trunk *g* to the organ bellows *h*. The wheel *i* is connected with a wire that controls the lever *k* of the governing valve of the water-supply pipe. As the bellows *h* becomes inflated, the block on its upper lid strikes against the lever *m*, closing partially or entirely the valve, and automatically regulating the supply of air to the demand. By means of a hand-wheel *i*, which can be conveniently reached by the organist, a valve *k* is opened or closed for admitting or cutting off the water supply. In this engine the crank is dispensed with, and the valve-gear so arranged as to prevent stoppage on the dead centers.

A number of reed instruments are called organs, being on the accordeon or melodeon principle, free reeds played by keys in one or more banks. Such are known as cabinet, parlor, and small choir organs.

Fig. 3427.



Lascell's Organ-Blowing Apparatus (Dr. Partridge's Church, Brooklyn, N. Y.).

Pipe organs are also made of a cabinet size. The *hand* or barrel organ is also a pipe organ in which the keys are moved by pins (staples) on a barrel moved by a crank, the arrangement of the pins being on a similar principle to that of a musical-box.

The *electric* organ is one in which the valves admitting air to the pipes are opened and closed by electro-magnetic action. The general arrangement is as follows:—

Each key has a separate insulated wire, the circuit through which is closed by depressing the key, causing a communicator to dip into a minute cup of mercury, the current thus established exciting a small electro-magnet that attracts a pallet or keeper, by which the valve is opened and remains so until the finger is withdrawn from the key, causing the pipe to *speak*. The battery employed is composed of glass vessels containing sulphate of mercury arranged on the upper surface of the bellows; when these rise, plates of zinc, each placed between two plates of gas-retort graphite, dip into the solution. No action is therefore exerted except at this time, and thus waste of battery power is avoided.

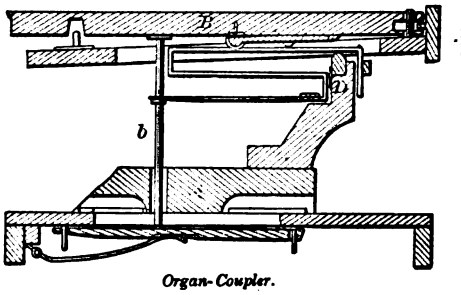
The arrangement admits of the key-board being placed in any convenient position, and at any distance from the instrument; the touch required for operating the keys is also much lighter than is required for an ordinary instrument.

Or'gan-coup'ler. (*Music.*) A device for connecting two sets of keys in an organ, so that by operating a lever or pedal each key when struck sounds the octave as well as its own note.

In Fig. 3428 the coupler is a bent wire, having a collar at one end which slips over the tracker-pin *b* that connects the key *B* and its valve. By a movement of the lever *D* the coupler may be caused to

Digitized by Google

Fig. 3428.



Organ-Coupler.

sound a note an octave higher than that of the key *B*, or may be thrown out of adjustment, so that only the note proper to that key will be produced.

Or'gan-die. (*Fabric.*) Fine Swiss figured muslin for ladies' summer wear.

Or'gan-har-mon'i-con. (*Music.*) A large *harmonium* or cabinet organ.

Or'gan-loft. (*Building.*) That part of a church designed for receiving the organ and its appurtenances. Usually an end gallery is chosen for this purpose. In ancient buildings it was customary to place it at one side of the choir, usually the north.

Or'gan-pipe. (*Music.*) A tube in which air is vibrated to produce a musical sound.

The organ-pipe is of two kinds: —

1. The *flute* or *mouth* pipe.
2. The *reed* pipe. See PIPE.

"The vibrating body in the organ-pipe is not the pipe, but the air contained in it. An agitation produced in the air at one end of the pipe is communicated to the other end, and reflected backwards and forwards from end to end, producing isochronous (or equal-timed) impulses, the frequency of which depends entirely on the *length* of the pipe. Hence, all organ-pipes of the same length yield the same note as to *pitch*, its quality only being affected by the form or material of the pipe. It will thus be at once perceived that the lowest C (the waves of which are 64 feet long) requires a pipe of 32 feet to produce it; and that all notes, from this to the shrillest whistle, are easily calculated, by dividing 550 feet by the length of the pipe." — TOMLINSON.

Fig. 3429 illustrates an organ-pipe of the *mouth* or *flute* kind. On opening the proper valve by depressing its key, the compressed air from the wind-chest passes through the tube *a* into the chamber *b*, and is directed with some force through a narrow slit against the sharp edge *c*, formed by beveling one of the sides of the pipe.

Fig. 3429.

Organ-Pipe.

In the *reed*-pipe the vibration of the air is caused by a metallic tongue affixed or inserted in the *reed*, a tube having a slit throughout its length, and fixed within the pipe.

Or'gan-zine. *a.* A silk thread made of several *singles*, *thrown* together. *Thrown-silk.*

b. Silk fabric made of such thread.

A *single* is a reel thread twisted. Several singles are twisted together in a direction the reverse of that of the singles, making *thrown-silk*. The *single* receives a twist to the left, is *doubled*, — that is, united with others, — and the combined threads are twisted to the right. *Organzine* is therefore *double-twisted thrown-sing'les.*

Orgues. 1. (*Fortification.*) Timbers shod with iron so suspended as to be dropped upon an enemy passing through a breach or gateway.

2. An arrangement of a number of parallel musket-barrels, so placed as to be fired simultaneously by a train of powder. Such was the weapon of Fieschi who fired at Louis Philippe, and it may be held to be the predecessor of the MITRAILLEUR (which see).

O'ri-el. 1. The bow-window of English domestic architecture. Sometimes it is of two stories. Sometimes it does not reach the ground, but is supported by corbels.

2. A recess within a building, as a window-way, closet, or chamber.

O'ri-en-ta'tion. The placing with an eastern aspect or presentation. From Lat. *oriens;* Sc. *sol*, rising.

(*Surveying.*) The determination of the east point in taking bearings.

(*Architecture.*) The placing of a church so that its chancel is toward the east.

O'ri-ent-a'tor. (*Surveying.*) An instrument used in regulating the ground plan of a church, so as to present the chancel to the east.

O-ril'lon. 1. (*Fortification.*) A curved projection formed by the face of a bastion overlapping the end of the flank, intended to protect the latter from oblique fire.

2. An earthen mound faced with brick.

Or'leans Cloth. (*Fabric.*) A ladies' dress-goods, having a cotton chain and woolen filling. It has a self color and highly finished surface.

Or'lo. (*Music.*) A Spanish wind-instrument.

Or'lop. (*Shipwrighting.*) *Orlop-deck, orlop-beams,* are, respectively, the lowest deck of a ship, or beams occupying the corresponding position. The deck is below the water-line, and may be occupied by the magazine, cock-pit, and for stores.

Or'mo-lu'. (*Alloy.*) *a.* A brass used for cheap jewelry. Copper, 48; zinc, 52.

b. Bronze or copper gilt also goes by this name. See ALLOY.

Or'mo-lu'-var'nish. An imitation gold varnish.

O'ro-ide. (*Alloy.*) An alloy resembling gold in appearance. One formula for its production is, —

Copper	100
Zinc or tin	17
Magnesia	6
Sal-ammonia	3.6
Quicklime	.12
Tartar of commerce	9

The other ingredients are added in small quantities to the fused copper and stirred in; the zinc last. Fusion is then maintained for about 35 minutes, when the dross is skimmed off, leaving the alloy fit for use. It is largely employed in the manufacture of cheap watch-cases.

Another formula is, -

Copper	79.9
Zinc	13.05
Nickel	6.09
Iron	.28
Tin	.09

The latter two are, perhaps, merely accidental ingredients. See ALLOY.

Or'phe-on. (*Music.*) A musical instrument of the melodeon order.

Or're-ry. A planetary machine to illustrate and explain the motions of the heavenly bodies. Its invention appears to have been coëval with the construction of the clepsydra and other horological automata. It was so called from the Earl of Orrery, who bore the expense of one constructed in 1715 by Rowley, after a pattern devised by the clockmaker George Graham. See PLANETARIUM; TELLURIAN.

The heliocentric theory was held by the ancient Egyptians, and taught by them to Pythagoras. The theory did not flourish in Greece. Plato mentions

Digitized by Google

it. A few scholars, like Nicolas (probably of Laodicea, fourth century A. D.), entertained it during the vast intervening period, and it was eventually revived by Copernicus.

When the Spaniards conquered Peru, they found the natives in possession of the true theory, considering the sun the center of our system.

The Chinese annals state that Tsi-ang-nung, in the reign of Shu-en-ti (126 – 145 A. D.), made an orrery to represent the apparent motion of the heavenly bodies round the earth, the instrument being kept in motion by the dropping of water from a clepsydra. There is a reference also to a similar instrument in the third century.

A planetarium is described in a letter from Angelo Politiano to his friend Francesco Casa, as seen by the former at Florence in the fifteenth century. The inventor was one Lorenzo of Florence, and the apparatus was constructed to illustrate the Ptolemaic theory of the heavens. The various parts were moved by trains of cog-wheels. Life of A. Politiano, published by Cadell and Davis, London, about 1800.

A planetary clock was made by Finee, 1553, and a planetarium by De Rheita in 1650.

Or'se-dew. Leaf metal of bronze. Dutch metal.

Or'tho-graph. A drawing representing a structure in *elevation*, external or internal. The internal *orthograph* is usually termed a vertical section or *sciagraph*.

The ground plan is the *ichnograph*.

The view of the whole building, the *scenograph*.

Or-tho-scop'ic Lens. (*Optics.*) An arrangement of two achromatic compound lenses, separated by an interval.

Or-tho-pæ'dic Ap-pa-ra'tus. (*Surgical.*) A device to correct the deformities of children, such as curved spine, club-foot, etc. See CLUB-FOOT APPARATUS.

Os'cil-lat-ing-cyl'in-der Steam-en'gine. (*Steam.*) A simple form of engine, in which the cylinder rocks on trunnions and the piston-rod connects directly to the crank. It was invented by James Watt, and was brought into use by Maudslay. Watt's model, made at Soho in 1763, was exhibited at the London Exhibition of 1851.

Witty of Hull patented the oscillating cylinder in England in 1813. English patent, June 5.

Goldsworth Gurney was in some way associated with the improvement of it, and has been credited with the invention.

It was introduced by those two famous makers of marine and river engines, Maudslay and Field and Penn and Sons.

This engine has a cylinder mounted on gudgeons or trunnions, generally near the middle of its length, on which it is capable of swaying to and fro through a small arc, so as to enable the piston-rod to follow the movements of the crank, to which it is directly attached without the intervention of a connecting-rod. This construction is economical of space and weight.

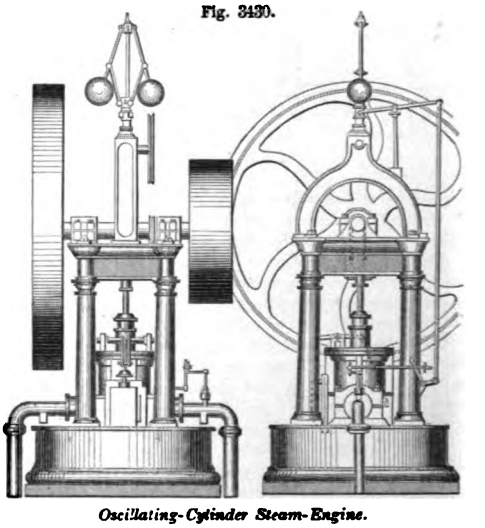
The trunnions are hollow, and are connected by steam-tight joints, one with a steam-pipe leading from the boiler, the other with an exhaust-pipe leading to the condenser.

The *valve-chest* oscillates with the cylinder.

Various arrangements are used to adapt the valve gearing to the oscillating motion of the cylinder and valve-chest. One of the simplest is to communicate motion from the eccentric to a sliding rod, on which is a *cross-head* of the form of an arc of a circle described about the axis of the trunnions, when the valve is in its middle position and having in it a slot of the same figure; in that slot is a slider attached to the end of a lever arm projecting from a rocking-shaft attached to the cylinder; another arm projecting from that shaft moves the slide-valve rod.

Another form of valve common in engines of this class is the trunnion-valve either of a disk form or having the shape of a frustum of a cone, in either case one portion of the valve having a rotary reciprocation derived from the oscillations of the cylinder.

Fig. 3430.

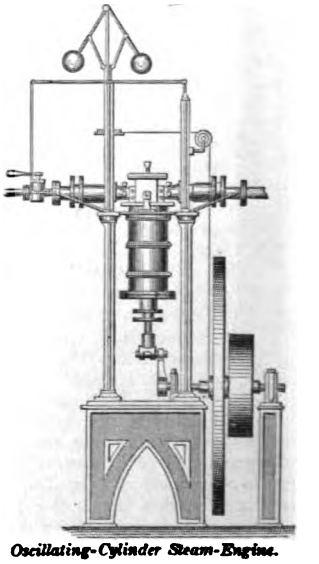


Oscillating-Cylinder Steam-Engine.

Fig. 3430 is an engine of this character for land use. The power may be communicated by a leather band over a pulley fixed on the axle of the fly-wheel, or by means of a spur-wheel and pinion. The steam is admitted through the hollow axle on one side, and withdrawn through a similar hollow axle at the opposite side of the cylinder.

The figure gives side and front elevations, respectively. The top works are supported by a four-column frame.

Fig. 3431.



Oscillating-Cylinder Steam-Engine.

Fig. 3431 is another form of oscillating-cylinder steam-engine, known as Joyce's pendulous high-pressure engine. The cylinder is inverted and oscillates on its trunnions after the manner of a pendulum. The piston-rod is connected directly to the crank. See also OSCILLATING-PISTON STEAM-ENGINE.

Fig. 3432 is a transverse view of a low-draft river steamboat with a pair of oscillating engines and feath-

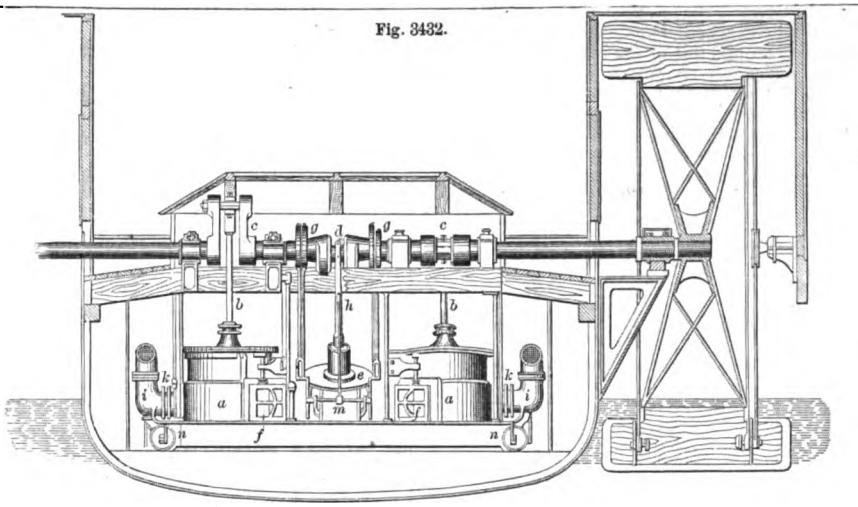
Fig. 3432.



Oscillating Engine on Low-Draft River Steamer (Thames).

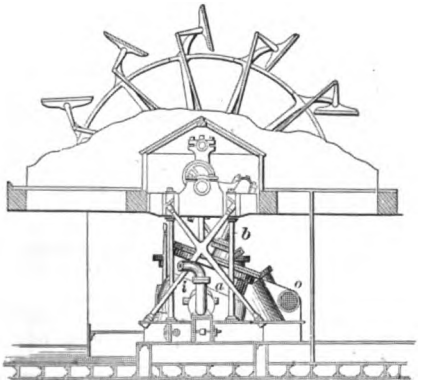
ering paddle-wheels. Fig. 3433 is a side view, showing one cylinder inclined, and the upper portion of the wheel with its floats in their changeable positions. The engines are coupled by an intermediate shaft having a crank which operates one or more air-pumps.

a a are the steam-cylinders; *b b*, the piston-rods, connected immediately with the cranks *c c*; *d*, a crank in the intermediate shaft, working the piston-bucket of the air-pump *e*; *f f* are slide-valves regulating the admission of steam to the cylinders; *g g*, double eccentrics on the intermediate shaft, operating the valves *f f*, enabling a link motion to be employed.

h is a handle by which the engines may be stopped, started, or reversed.

i i are steam-pipes leading to the trunnions *k k*, on which and on other trunnions connected with the pipe *m* the cylinders oscillate; *n n* are pumps, the pistons of which are attached to the trunnions and worked by the oscillations of the cylinders; *o*, the waste-water pipe from the condenser.

Fig. 3433.

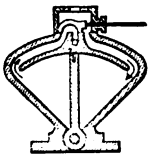


River Steamer Engine (Side View).

Os'cil-lat-ing-pis'ton Steam-en'gine. A form of steam-engine in which the piston oscillates in a sector-shaped chamber. By means of a slide or other valve the steam is admitted to alternate sides of the piston, which imparts a rotary reciprocation to the rock-shaft.

The engine (Fig. 3435) has a piston planted on an axis and has an oscillation in a vertical plane.

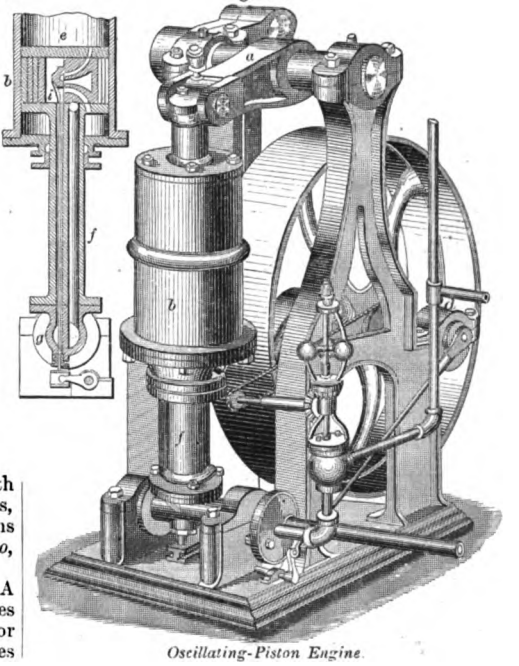
Fig. 3434.



Oscillating-Piston Engine.

The cylinder *b* is attached to the walking-beam *a*, which oscillates on a rock-shaft, and whose other arm is connected by a pitman with the fly-wheel crank. The piston is at the upper end of a hollow rod *f*, which also oscillates on a hollow rock-shaft *g* divided into two compartments. The piston is hollow, forming a steam-chamber, within which is a slide-valve *i*; it has also

Fig. 3435.

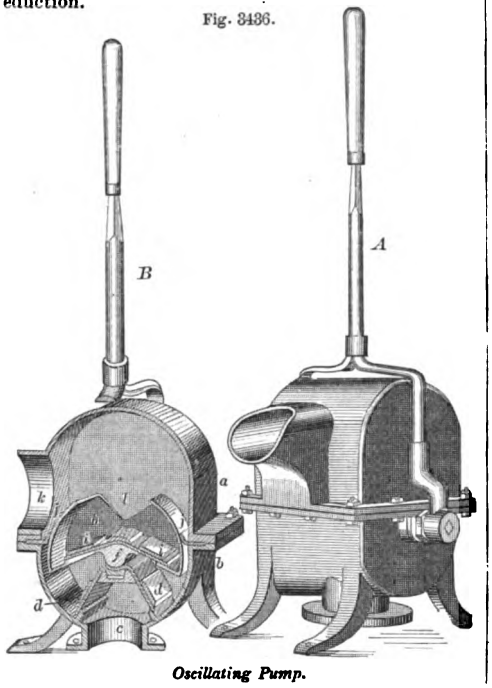


Oscillating-Piston Engine.

Digitized by Google

suitable inlet passages and an exhaust passage. Steam is admitted through one of the induction-passages of the rock-shaft *g* and piston-rod *f*, alternately above and below the piston by means of the slide-valve *i*, operated by a rod extending through the induction-passage of the piston-rod and reciprocated by a small rock-shaft connected with the crank-shaft; this causes the reciprocation of the cylinder, while the piston oscillates upon the rock-shaft *g*. The other passages of the piston-rod and rock-shaft serve for eduction.

Fig. 3436.



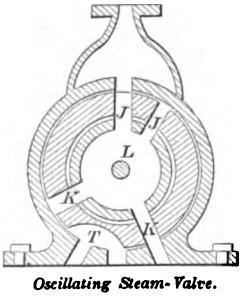
Oscillating Pump.

Os'cil-lat-ing Pump. The pump, Fig. 3436, is made in two sections *a b*, flanged and bolted together. The induction-chamber *c* has upwardly opening valves, through which water is drawn by oscillating the handles *A B*, causing corresponding oscillation of the shell *j j*, which turns upon *f* as a center, and is divided by radial plates provided with upwardly opening valves *d i* into chambers into which the water is successively admitted at each oscillation and discharged through the eduction-opening *k*.

Os'cil-lat-ing Pump-spear. (*Nautical.*) A revolving arrangement like a winch, for working a pump-rod.

Os'cil-lat-ing Valve. 1. (*Steam.*) A valve which reciprocates on a pivot, as the disk and trunnion valves of oscillating-cylinder steam-engines.

Fig. 3437.

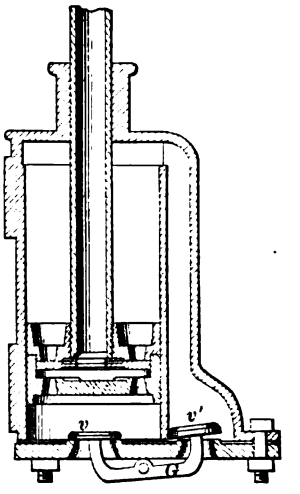


Oscillating Steam-Valve.

In Fig. 3437 steam is admitted to the center *L* of the hollow valve, through passages *J J*, communicating with the steam-chest; *K K* are induction-openings to the steam-cylinder; *T*, eduction-port.

Oscillating steam-engines frequently have oscillating valves working in their trunnions. Others are oscillated by bar or crank connection to a fixed object while the cylinder vibrates.

Fig. 3438.



Oscillating Pump-Valve.

2. A pump-valve which reciprocates on a pivot. In the example, the valves *v* and *v'* are attached to a lever *G*, and batter upon their seats alternately.

O'si-er-peel'er. (*Agriculture.*) The process of peeling osiers by a cleft stick is shown at Kouna, Thebes. The uses of the osier among the ancient Egyptians were constant and various. Baskets were even more common then than now, as the products of the field, the net, and the hook were generally carried by men. The wheeled vehicles in Egypt were few and not capacious.

Machines for peeling osiers proceed in various ways. In Colby's, the osier wands are carried between vulcanized rubber rollers which press, rub, and wring the bark from the wood. A serrated metallic roller acts in connection with an elastic or yielding roller, both having an end chase or lateral reciprocation to rub off the bark of the wand. A rack or comb catches and removes the bark.

Easterbrook's has a pair of rollers, respectively convex and concave, which give a slipping pressure upon three sides of the wand and loosen the bark; a pair of wire brushes next come into play, and then rollers discharge it from the machine.

Other forms have rollers having various angular presentations to a disk against which they press the wand. Another has jaws to drag the willow past V-edges. Another rubs the willow between a wheel and a traveling belt.

Os'le-on-i'ron. (*Metallurgy.*) Bars specially made for the manufacture of wire.

Os'mi-um. Equivalent, 99.6; Symbol, *Os.*; specific gravity, 21.4; nearly infusible. A rare metal, sometimes found in a native alloy with iridium, and forming the hardest alloy known.

Os-mom'e-ter. An apparatus for exhibiting the force of osmotic action, by which liquids are impelled through a moist membrane, illustrating the phenomena of *endosmose* and *exosmose*. The device consists of a porous vessel or sac containing a saline solution and plunged in pure water.

The more rapid flow through the porous septum or wall is from the thinner fluid to the saline solution, and is termed *endosmose*. A slower current sets in the other direction, and is called *exosmose*. The result is a blending and ultimate uniformity of quality.

Os'mund Fur'nace. (*Metallurgy.*) A furnace formerly employed in Sweden and still employed to some extent in Finland for reducing bog-iron ore. This ore, consisting essentially of hydrated sesquioxide of iron, is extracted from the bottoms of lakes and rivers. It occurs in grains, cakes, or amorphous

Digitized by Google

masses, generally of a somewhat loose and friable texture, different varieties yielding from 25 to 50 per cent of pure iron.

The illustration is taken from a cut in Swedenborg's work on iron. *a* is a heap of the ore not calcined; *b*, a heap undergoing calcination on wood; *c*, calcined ore; *d*, borer employed in searching for ores; *e*, charcoal rake; *f*, iron shovel; *g*, tongs for withdrawing the bloom from the furnace; *h*, cinder hook, also used in taking out the bloom; *i*, bar for cleaning the cinder hole and tuyere hole; *j*, sledge used for hammering the bloom when taken out; *k*, lump of iron, *blästra*, or *osmund*, partly divided; *l*, hatchet; *m*, treadles for working the bellows; *n*, inclined plane for conveying ores to the top of the furnace; *o*, tap hole for cinders; *p*, tuyere; *q*, wood shovel for charging the furnace with ore. The female in the figure is engaged in spinning with the distaff and operating the treadles of the bellows at the same time. The furnace has a rectangular cavity at the bottom, into which the reduced iron was

Fig. 3439.

Osmund-Furnace.

received, and which is provided with an opening near *q*, through which the bloom is extracted. During the operation of smelting this is built up temporarily with stones. The inner lining is of refractory stone, and between this and the outer wooden casing is a filling of earth. The iron produced may be forged, but is usually of a mixed character, requiring to be remelted to render it malleable.

A furnace of this kind yielded about 1½ tons of iron weekly, of which from 33 to 50 per cent was lost in working it up into an *osmund* or bloom. In Finland, as has been observed, this primitive contrivance still maintains its ground beside the high-blast furnace, seeming to be well adapted for producing a good quality of iron from the peculiar ore employed. It formerly afforded lucrative employment to the Swedish peasant during the winter season. When the farm labors of the year were over, he went into the woods for some weeks with his wife and family, with whose aid he extracted the iron, which was sold for a small amount of ready money at some market town.

Os'na-burg. (*Fabric.*) A kind of coarse linen, made of flax and tow, originally imported from Osnaburg, Germany.

Os-te'o-tome. (*Surgical.*) An instrument to cut a bone; specifically, one to cut the bones of the fetal cranium when it is necessary to much reduce it to facilitate delivery.

Ot-a-cous'tic. (*Surgical.*) An instrument to improve the sense of hearing.

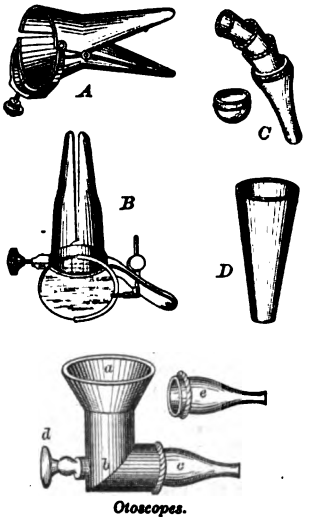
O'tho-scope. (*Surgical.*) An instrument invented in 1851 by Czermak, for holding water round the eye to enable the interior to be seen. It has the effect of preventing the cornea acting as a convex refracting surface. It is a little reservoir of glass, having three sides, and when placed against the cheek and nose and filled from above with water, the eye can be kept open in it under the water. It is superseded by Helmholz's OPHTHALMOSCOPE (which see).

O'to-phone. An ear-trumpet.

O'to-scope. (*Surgical.*) *a.* An instrument for viewing the interior of the ear. *Otoscopium.*

To this class belong the different patterns of ear-speculums (*C D*), funnel-shaped, of high polish inside, through which light is reflected by means of a concave mirror; and the bivalve speculum *A*, which admits of expansion of the meatus auditorius, etc.

Fig. 3440.



Simrock's otoscope (*B*) is a funnel-shaped bivalvular instrument with magnifying-glass.

Clark's reflecting otoscope (lower figure) consists of an angular tube, one extremity of which is expanded to receive the rays of light from the window, a gas-jet, or lamp, while the other is prepared for the adaptation of specula of various sizes.

Otoscopes.

The light enters at the flaring extremity, and is reflected from the surface of a polished steel mirror, which is placed transversely across the angle *b*, and is thrown upon the tympanum through the speculum *c*. A small tube proceeds from the eye-piece *d*, and, transfixing the mirror, extends just into the speculum *c*. At the extremity of this tube, a carefully ground lens is introduced, which greatly magnifies the objects which are seen through the speculum. The smaller speculum *e* can be adjusted in place of the one upon the instrument when required.

b. An instrument enabling the examiner to detect the sound of air passing through the tympanitic cavity in certain morbid conditions. An *ear-explorer*.

The *otoscope* of Toynbee is an elastic tube with ivory extremities, one to fit the operator's, the other the patient's, ear. Air being blown into the eustachean canal, you determine with it whether the tympanum be sound or perforated.

Ouch. Formerly *ouche;* see King James's translation of the Bible, Exodus xxviii. 11: —

"Engrave the two stones [onyx] with the names of the children of Israel; thou shalt make them to be set in *ouches* of gold."

Also in Exodus xxxix. 18: —

"And the two ends of the two wreathen chains they fastened in the two *ouches* and put them on the shoulders of the ephod, upon the forefront of it." — BISHOP'S "Bible," 1568.

The collet of a jewel.

Digitized by Google

The part of a setting which grasps the stone. The *bezel*.

An ornamental collar of gold.

From the word *ouche* comes *brooch*, the modern name of the ornamental dress-clasp. This was formerly a clasp or button, and by the addition of a *broach*—a pin—(Fr. *broche*), received its present form.

Out'burst-bank. (*Hydraulic Engineering.*) The middle portion, as to elevation, of a sea embankment. The lower portion is the footing, and has a base of 5 to a hight of 1. The *outburst* has a base of 2 to 1 of hight, and is crowned with the *swash-bank*, which has the same proportions and a level on top of 4 to 5 feet under ordinary circumstances, where it is not to be used as a road.

Out'crop. (*Mining Engineering.*) The emergence of a stratum or seam at the surface. *Basset.*

Out'er Form. (*Printing.*) The form commencing with the first page of the sheet. It is usually worked off last.

Out'fall. (*Hydraulic Engineering.*) The point of discharge for, or the embouchure of a drain, culvert, or sewer.

Out'haul. (*Nautical.*) A rope used to extend the clew of a boom-sail.

Out'keep-er. (*Surveying.*) A small dial-plate having an index turned by a milled head underneath, used with the surveyor's compass to keep tally in chaining.

The dial is figured from 0 to 16, the index being moved one notch for every chain run.

Out'rig-ger. 1. (*Nautical.*) *a.* A spar for extending a sail or rope beyond the points of attachment furnished by the hull.

b. A boom rigged out from a vessel to secure boats to when the vessel is at anchor.

c. A floating timber attached by spars to the hull and floating parallel therewith. Used with crank or narrow boats to support them upright in the water under a press of canvas which would otherwise upset them. Principally used with the *proas* of the Malays and Ladrones. The lesser or leeward boat of the double canoe of the Pacific-Islanders is called a *hamma*.

d. A spar projecting over the stern of a boat for assistance in hauling out the *clew*.

e. A light boat for matches.

2. (*Gearing.*) A wheel or pulley outside the frame to receive a belt or other driving connection.

3. Of a crane; the *jib*.

4. The cat-head.

5. (*Building.*) A beam projecting outwardly from a wall to support a hoisting tackle.

Out'side Car. (*Vehicle.*) An Irish jaunting-car in which the passengers in two rows sit back to back, with their feet on boards outside of the wheels. The *inside* variety is shown under CAR.

Out-sid'er. (*Locksmithing.*) A pair of nippers with semi-tubular jaws, adapted to enter a keyhole and grasp the pin of a key, so as to turn it and unlock the door from the outside.

Out'side Bel'ly-band. (*Harness.*) An extra belly-band used on single harness, to prevent the thills rising too high.

Out'works. (*Fortification.*) Works included in the defense of a place, but outside the *parapet*. *Detached* works are beyond the *glacis*.

Ou-vreaux'. (*Glass.*) The *peep-holes* of a plate-glass furnace.

O'val Chuck. A chuck invented by Sharp, for oval or elliptic turning. See CHUCK.

O'val Com'pass. A compass for describing ovals. See ELLIPSOGRAPH.

O'val File. A file whose cross-section is elliptical or oval. Used sometimes as a *gulleting* file. Called by the French *limes à double dos*.

Ov'en. A chamber in which objects are baked by artificial heat.

The division may be made into these kinds:—

1. *Domestic.*
2. *Baker's.*
3. *Metallurgic.*
4. *Glass-annealing.*
5. *For clay and ceramic ware.*

The oven of the Society-Islanders is a pit in the ground paved with large stones, over which a fire is lighted. When the stones are hot enough, the embers are removed, the stones covered with green cocoa-nut leaves, the dressed pig wrapped in plantain-leaves, placed in the hole, and covered with hot embers, on which are placed bread-fruit and yams wrapped in plantain-leaves. Captain Cook said it was the best mode of cooking he ever saw. It is a pity that he was afterward subjected to it. He was sent by the English government to the South Seas to observe a transit of Venus, and was killed and eaten by the natives of Owhyhee, February 14, 1779.

The early Egyptian oven was a crock sunk in the ground and heated by a fire built inside. To the sides of the crock wet lumps of dough were attached and baked by the heat. It explains how the frogs with which Egypt was plagued came into the *ovens*. The cannibals of the Feejee Islands make a hole in the ground, and place therein the meat (*bakolo*, long pig, as they called a human carcass) and heated stones, covering all with leaves. The Rocky Mountain Indians collect the grasshoppers in pits, and there cook them with heated stones. These are primitive ovens, and with certain variations may be found among most barbarous nations and among some who have retained primitive customs.

1. The domestic ovens are of three kinds:—

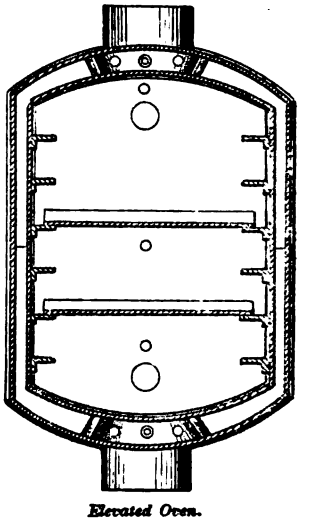
a. Stove ovens.

b. Dutch ovens, so called.

c. Out-ovens, heated by fuel. These resemble the baker's ovens.

a. Stove ovens are usually a part of the stove, and vary in their position with the shape and capacity of the stove. Several forms are shown under COOKING-STOVE, p. 615.

Fig. 3441.



Elevated Oven.

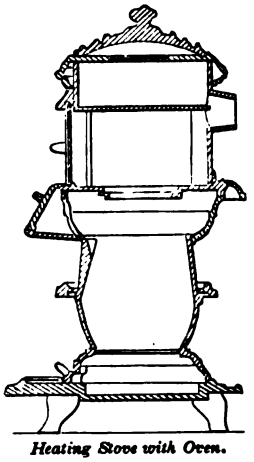
The oven of the range is alongside the fire-chamber, as in Fig. 1435, p. 614. See also RANGE.

The *elevated oven* is a chamber surrounded by a spreading or enlargement of the flue, as in Fig. 3441. See also Fig. 1439, p. 615.

Another form is an oven combined with a heating stove, some varieties of which are known as "parlor cooks." Fig. 3442 is an instance, in which the cast-iron fire-chamber is surmounted by a cap, and the latter by a cylindrical casing containing an oven encompassed by the caloric current. It combines in small compass heating and cooking arrangements.

Digitized by Google

Fig. 3442.



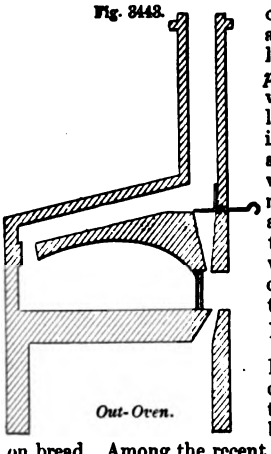
Heating Stove with Oven.

b. The *Dutch oven*, so called, is of two kinds. One is a *skillet* or *baking-pot*, used in cooking by wood coals on the hearth, the iron pot being set upon a bed of hot coals and others piled on to its lid.

The other form is a sheet-metal affair placed in front of a fire in a grate, so as to cook by radiation from the open fire, the closed back of the chamber keeping in the heat. See Fig. 1809, p. 765.

c. The *out-oven*, as it is called, was commoner aforetime than now. It is so called because built out of doors; not a *house*-oven. It has a domed chamber, is built of brick, and is heated by means of light wood or sticks burned inside. The bricks having been well heated by the fire inside, the ashes and embers are raked out, the floor swept, and the batch of dough loaves introduced by a *peel*, which is a flat wooden shovel with a long handle. The door is then closed. The result is very satisfactory when good material meets with good management. The illustration shows a form with a front, back flues, damper, a rake-hole for the embers, and an ash-pit beneath.

Fig. 3443.



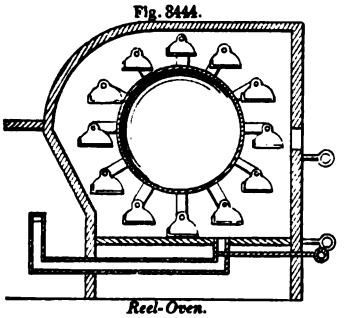
Out-Oven.

Loaves found in a Pompeian bakery indicate that the name of the meal, wheat, rye, beans, etc., was stamped on bread. Among the recent discoveries in a baker's oven, so hermetically sealed, says Marc Monnier, that not a particle of volcanic ashes had entered, there were eighty-one loaves, whole, hard, and black, found just as they had been placed on the 23d of November, A. D. 79. Enchanted with the discovery, Fiorelli himself climbed into the oven and took out the precious relics with his own hands. Most of them weigh about a pound, are round, depressed in the center, and divided into eight lobes. Loaves precisely like them are still made in Sicily.

2. The *baker's oven*. *a.* Until lately, and even now in many places, this was but an extension of the one last described; the additional capacity enabling it to act upon a larger quantity, and the larger size requiring greater skill in the building and the mode of conducting and using the heat economically. Some ovens of this kind are heated by steam.

b. The *reel-oven*. This has a series of pans or trays suspended from the periphery of a skeleton cylinder, or, as it were, from the spokes of two wheels keyed on to the same shaft. The pans are preserved in a horizontal position by means of suspending each from a point above its center of gravity (Ball, September 23, 1856; McKenzie, May 1, 1860; Coburn, January 30, 1872); by a suspended weight beneath the pan (Ball, July 19, 1870); by radius rods like those of a feathering paddle-wheel (McKenzie, June 6, 1871).

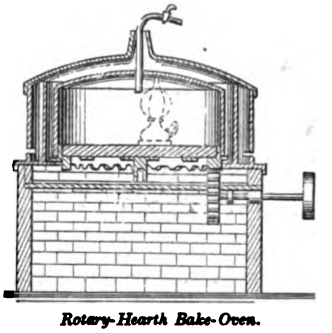
Fig. 3444.



Reel-Oven.

The reel-oven is shown in Fig. 3444. The rate of revolution is such that a loaf is baked during one revolution. As a pan comes opposite the mouth of the oven, the baked loaf is taken off and a loaf of dough placed upon it. The pans are hung to radial arms projecting from a rotating drum which reflects heat upon the top of the matters contained in the pans. Flues within the oven have dampers by which the escape of heat to the chimney may be permitted. The work is thus continuous, the door being closed in the intervals of taking off the bread and putting on the dough as the pans arrive in succession opposite to the doorway. The reel is turned by a wheel on the axis which extends outside the wall of the oven.

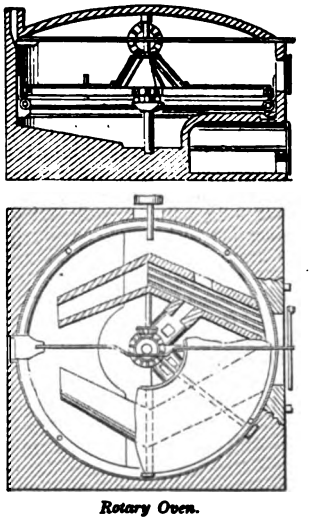
Fig. 3445.



Rotary-Hearth Bake-Oven.

c. The *traveling-apron* oven is another form of continuously working oven. In Crumbie's oven, April 9, 1872, shelves are suspended from a series of traveling axles, which are connected by an endless chain of bars and caused to travel in an elliptical path, presenting the shelves consecutively at the oven door, as described just above. An endless-apron oven was patented by Deneale in 1806.

Fig. 3446.



Rotary Oven.

d. An *endless chain* with suspended trays, traveling in a tall vertical flue, is shown in Jennison's patent, February 1, 1859.

Digitized by Google

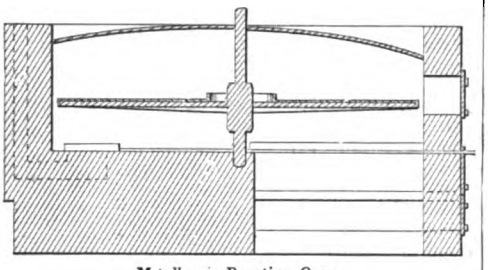
c. The *rotary hearth* is a circular floor having a cogged rim or a stem with a gear-wheel upon it.

Fig. 3445 is an illustration of the former, and Fig. 3446 of the latter. In each case, the floor for the bread is in a dome-roofed chamber, heated from the furnace beneath. The oven usually forms a part of the flue, the heated gases from the fire passing into and through the oven. The lower part of Fig. 3446 shows the duplicate arrangement of fireplace and the distribution of the heat.

3. *Metallurgic ovens.* These are of two kinds.

a. Roasting ovens, which may be properly termed *furnaces*, as in the example, where pyrites or arsenical ores are exposed to a calcining heat by which

Fig. 3447.



Metallurgic Roasting-Oven.

they are rendered friable, the metallic portion being oxidized and converted in a calx. See also ORE-CALCINING FURNACE; ROASTING-FURNACE.

b. The *annealing oven*, in which iron articles are brought to a heat below fusion-point and then allowed to cool gradually, so as to decarbonize them and remove the brittleness of their ordinary "cast-iron" condition. See MALLEABLE-IRON FURNACE; ANNEALING-FURNACE, Fig. 251, p. 114. See also ANNEALING, pp. 110–114.

Other heating-chambers may be termed *ovens;* such as the *assay-furnace*, Fig. 395; the *muffle-furnace;* the *vulcanizing-furnace*, etc.

4. The *glass-annealing oven* is a chamber in which blown, pressed, or rolled glass is placed to allow it to cool slowly, in order that the particles may arrange themselves in a static condition, not liable to fracture and fly to pieces upon slight provocation. See ANNEALING, p. 110; LEER.

5. *Porcelain oven.* The firing-kiln of the porcelain manufacture. The ovens are conoidal structures of brick, 22 feet in diameter and 18 to 21 feet high, and are clustered around a brick building of similar structure, but larger, called a *hovel*.

The *ovens* are heated by fireplaces or *mouths*, about 9 in number, built around them. Flues in connection with these converge under the bottom of the oven to a central opening, drawing the flames to this point, where they enter the oven; other flues, termed *bags*, pass up the internal sides to the hight of about 4 feet, conveying the flames to the upper part. See PORCELAIN; POTTERY.

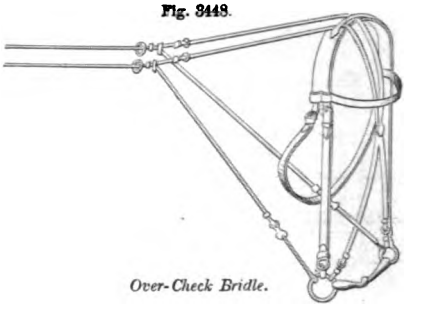
O-ver-cast'ing. 1. (*Bookbinding.*) The doubling of an edge of a single leaf or plate to be sewed in, so as to give a hold to the thread.

2. (*Sewing.*) Laying two edges of cloth together and whipping them by a thread which goes over and over. Used to prevent raveling of the edges of two fabrics sewed together.

O'ver-check. See OVER-CHECK BRIDLE.

O'ver-check Bri'dle. (*Harness.*) A driving-bridle having a rein passing over the head of the horse, so as to draw the bit upward into the angle

Fig. 3448.

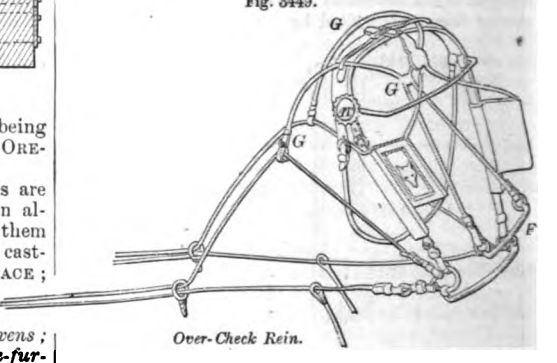


Over-Check Bridle.

of the horse's mouth. In the example, branch reins are attached to each end of the driving-reins, one branch answering for a gag-rein, passing over the horse's head to the ring of the snaffle-bit; the other branch connects to the same ring of the bit. The devices correspond on each side.

O'ver-check Rein. (*Harness.*) A rein passing over the head of the horse to the bit, so as to pull upward upon the bit when drawn upon. The

Fig. 3449.

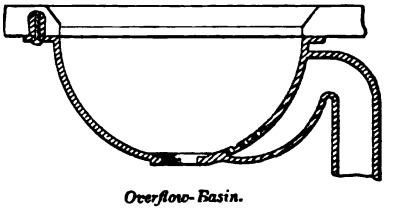


Over-Check Rein.

example shows one which has an additional or safety rein which leads through the runners to the rings of the usual bit, and also draws upon the *over-check* rein *G*; this is connected to a separate bit *F*, which is thereby pulled upward against the palate.

O'ver-flow-ba'sin. One having a pipe to convey away excess of water and prevent it running over the brim. In the example, the overflow holes are near the bottom, but communicate with an up-

Fig. 3450.



Overflow-Basin.

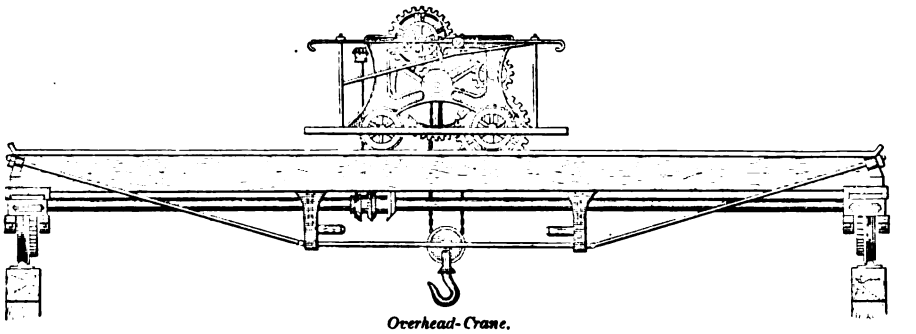
wardly bent pipe to allow the basin to hold water up to a given level.

O-ver-haul'. (*Nautical.*) To extend the blocks of a tackle from each other and slacken the fall, that it may render through the blocks. To *fleet*.

O-ver-head'-crane. One which travels on elevated beams in a foundry, machine-shop, or on high scaffolding above a structure. The crab travels on wheels, and the object is suspended from chain-tackle beneath. See also STEAM-CRANE.

Digitized by Google

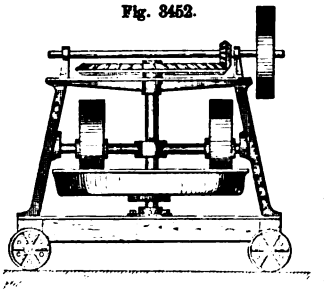
Fig. 3451.



Overhead-Crane.

O-ver-head'-gear. Driving-gear above the object driven, as in the mortar-mill, Fig. 3452, in which the bevel gearing driving the rolls of the Chilian mill are placed overhead, in contradistinction to such as receive the impulse from below, as in Figs. 146 and 147.

Fig. 3452.



Overhead Driving-Gear.

O-ver-head'-mo'-tion. (*Turning.*) A frame attached to the bench of a lathe, and rising to a hight about a foot above the head of the workman. It supports a spindle on which is a pulley driven by a band from the fly-wheel; another pulley on the same spindle carrying a band which passes down to the pulley on the spindle of the eccentric cutter. The latter spindle, to whose end the work is chucked, is stationary, while the cutter is revolved.

O-ver-head'-rein. One which passes over the horse's head, between the ears, and down the front of the face to the bit, so as to pull the latter up into the angle of the mouth, instead of pulling squarely against the jaw. See OVER-CHECK REIN.

O-ver-head' Steam-en'gine. An engine in which the cylinder is above the crank, the thrust motion being downward. Not an uncommon form with trunk and oscillating engines.

O-ver-heat'ing-pipe. (*Steam-engine.*) A pipe through which steam is caused to pass in order to be superheated.

O-ver-lap'-joint. One in which the parts lap upon each other, in contradistinction to a butting-joint, in which the edges merely are in contact. See ANGLE-JOINT, for a number of illustrations in which overlapping portions are joined by solder or by bending over upon each other.

O'ver-lay. (*Printing.*) A piece of paper pasted upon the tympan-sheet at a spot where the impression is desired to be dark and effective. This is used to bring out the darker parts of the engraving, while the lighter portions are partially relieved of pressure by *cutting out* the tympan-sheet over such places.

It is also used to obtain a proper impression of the low part of a form.

O-ver-reach'ing de-vice'. (*Menage.*) An attachment to the leg or foot of a horse to prevent the catching of the toe of the hind foot upon the heel of the fore foot in rapid traveling. See LEG AND FOOT GUARDS FOR HORSES.

O-ver-sail'ing. (*Architecture.*) Projecting beyond the general face.

O-ver-seam'ing. (*Sewing.*) Another name for overcasting, in which the edges of two pieces of cloth are laid together and whipped over and over, to prevent raveling.

O'ver-shave. (*Coopering.*) A jointer having a concave-edged bit, on which the backs of staves are dressed.

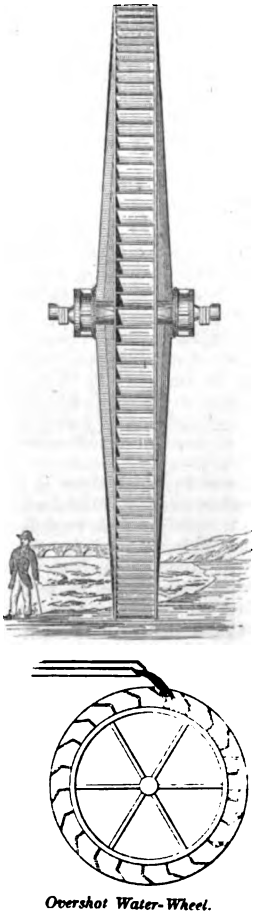
O'ver-shoe. 1. An india-rubber shoe to protect the usual foot-covering while walking in muddy streets. A *goloshe.*

2. A shoe of buffalo hide, hair inward, used in sleighing or winter traveling.

O'ver-shot-wheel. A form of water-wheel in which the water flows upon or near the top of the wheel, as in Fig. 3453. It acts principally by gravity, though some effect is of course due to the velocity with which the water arrives. Some overshot-wheels have a circular rack or cogged rim near the periphery, so as to bring the body of water in close proximity to a pinion which communicates the motion to the machinery. In such cases, the frame of the wheel is a skeleton, comparatively light. In ordinary cases, the wheel is united by the usual arms or spokes to an axis which forms the main driving-shaft.

The upper figure shows a large wheel of the latter description.

Fig. 3453.



Overshot Water-Wheel.

O'vo-lo. A molding whose profile is a quarter of a circle; or, in the Grecian, a portion of a cycloid.

Digitized by Google

A quarter-round. See MOLDING.

O'vo-lo-plane. (*Joinery.*) A joiner's plane for working ovolo moldings on sash, or elsewhere. Ovolo *routers* are made like spokeshaves, to work in circular sash-frames.

Ox-bow. (*Husbandry.*) The bent piece of wood which passes under the neck of the ox, the upper ends passing through the yoke. See OX-YOKE; YOKE.

Ox-brake. The ox-brake resembles that used for shoeing refractory horses, and consists of a stall where the neck is confined, straps to hold the animal suspended if he prove sullen and attempt to lie down, and posts and bars to which the feet are lashed for shoeing. See *a*, Fig. 3456.

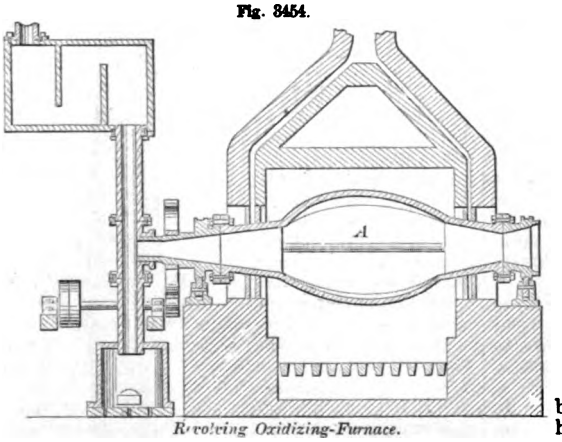
Ox-eye. (*Building.*) An oval *dormer*-window.

Ox'i-diz-ing-fur'nace. (*Metallurgy.*) A furnace for treating ores or metallic substances, in which the material is exposed to an excess of air, the oxygen of which unites with the metal, forming an oxide. With ores, it may be said to be roasting with an excess of air. The term is somewhat general, and to speak of *oxidizing*-furnaces is a mode of stating chemically the action of certain furnaces under given conditions of access of air. The same furnace might be a *reducing*-furnace were the air more nearly shut off. A *reducing* flame is one which has an excess of gases, and abounding in carbon, the effect of which is to take up the oxygen from the material, *reducing* it. A neutral furnace is one in which there is enough of air admitted for perfect combustion of the fuel, and no more; the effect is therefore *nil* as regards the question of *reducing* the oxide, or *oxidizing* the metal.

An illustration, from among many, may be drawn from the process of *puddling* iron. The flame is first an *oxidizing* flame with an excess of air, the oxygen uniting with the carbon of the metal to convert it into relatively pure iron; a *reducing* flame is then allowed for a while, the fuel being in excess, and carbonaceous gases going over to reduce the oxide; after this air in moderate degree is admitted, the fire burning clear and consuming the fuel perfectly, as near as may be, the flame being *neutral* and merely heating the iron.

In Fig. 3454 is shown an oxidizing furnace, in which the ores are rolled over and over to expose them more fully to the action of the air. The revolving chamber has hollow trunnions open at one end to the air, and at the other communicating with the chimney. The material in chamber *A* is heated by fire in the furnace beneath, and particles carried over are caught in the upper or lower chamber, according to their relative gravity.

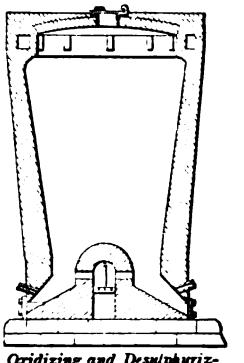
Fig. 3454.



Revolving Oxidizing-Furnace.

Fig. 3455 is a form of oxidizing and desulphurizing furnace for the treatment of auriferous pyrites and other similar ores with the gases formed by decomposing steam or superheated steam. The coal is placed in an ordinary fire-box, with grate-bars, so as to allow a good draft of air to support combustion. Steam from a boiler, which may be heated by the waste gases of the furnace, is brought into the incandescent coal in the fire-box. The resulting gases are passed into the chamber containing the ore to be treated. For the purpose of regulating the temperature of the gases in the ore-chamber, and to assist in oxidizing the metals, an additional supply of steam is passed into the ore-chamber without being passed through the fire-box.

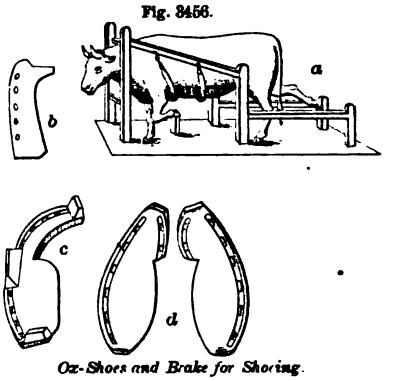
Fig. 3455.



Oxidizing and Desulphurizing Furnace.

Ox-shoe. Among the Orientals oxen to be shod are thrown, and their four feet drawn up into a bunch by cords. The animal being then helpless, the operation is completed at leisure.

Fig. 3456.



Ox-Shoes and Brake for Shoeing.

An ox-shoe consists of a flat piece of iron with five or six holes near its outer margin to receive as many flat-headed nails, whereby it is secured to the hoof. The shoe *b* represented has a projecting flap, which is bent into the cleft of the foot and flattened up against the inside of the hoof, to assist in keeping the shoe in place. This projection is not always employed. *c d* are also forms of ox-shoes.

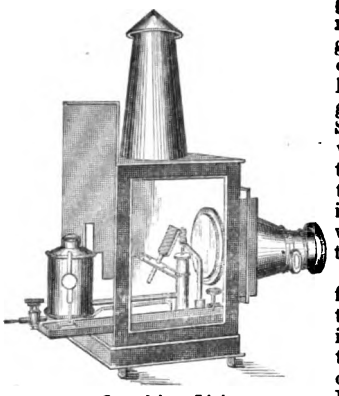
Ox-y-cal'ci-um-light. One produced by a jet of oxygen gas forced through the flame of an alcohol lamp on to a piece of lime. This light will exhibit the usual paintings on a screen 10 or 15 feet in diameter with very brilliant effect. It is not so brilliant as the oxyhydrogen light, but it is much safer to manage. The apparatus is less bulky, troublesome, and expensive. The light is equal in brilliancy to ten argand-lamps of ordinary dimensions.

See also CALCIUM-LIGHT; DRUMMOND-LIGHT; OXYHYDROGEN LIGHT.

Ox-y-ge-na'tor. A contrivance for throwing a stream of oxygen into the flame of a lamp.

Digitized by Google

Fig. 3457.



Oxycalcium-Light.

Ox'y-gen-gas Ap'pa-ra'tus. Oxygen gas was first discovered by Dr. Priestly August 1, 1774. Scheele and Lavoisier appear to have made the discovery independently very shortly afterward.

Dr. Priestly first obtained the gas by heating red precipitate (red oxide of mercury, HgO) to a temperature of 752° Fah., by which the oxygen is expelled from this compound. Lavoisier verified the result by boiling mercury in a given quantity of air, thus forming red precipitate. Scheele obtained oxygen while engaged in experimenting upon some of the ores of manganese.

It may be readily obtained by heating chlorate of potash, mixed with $\frac{1}{8}$ or $\frac{1}{4}$ its weight of black oxide of manganese, in a glass vessel to a temperature of 450° or 500° Fah., and collecting over a water-bath. This process is, however, rather expensive.

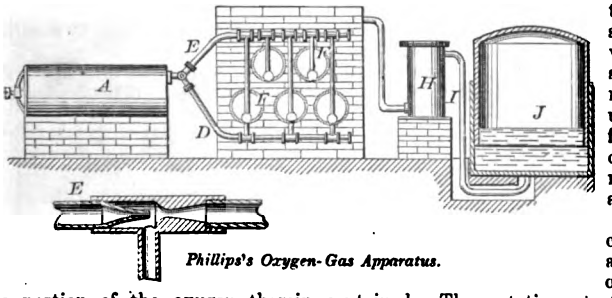
At the London Polytechnic Institute, where large quantities are used for the oxyhydrogen light, it is procured by heating black oxide of manganese (MnO_2) in wrought-iron bottles; two equivalents of the gas are liberated from each three molecules of the oxide, leaving Mn_3O_4, or red oxide of manganese.

A pipe is attached to the upper part of each bottle, through which the gas, after being purified by passing through a simple washing apparatus, is delivered into a copper gasometer. The pure oxide should yield $\frac{1}{5}$ its weight of the gas, but in practice rarely more than half that amount is obtained.

Fig. 3458 illustrates an apparatus for obtaining oxygen gas from permanganates by means of steam.

A is the boiler from which a current of steam is forced by the pipe *D* into the retorts *F*, extracting

Fig. 3458.



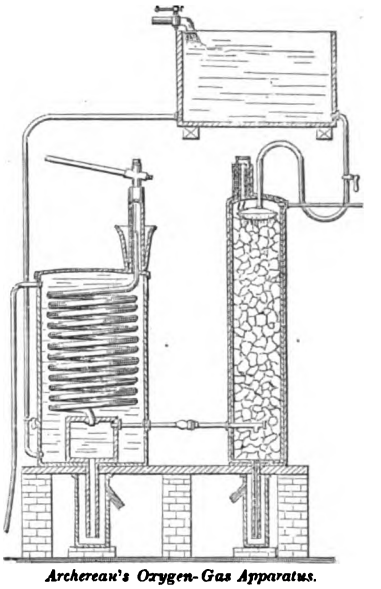
Phillips's Oxygen-Gas Apparatus.

a portion of the oxygen therein contained. The steam current then passes, carrying the oxygen with it into the condenser *H*, where the steam is condensed, the oxygen being conveyed through the pipe *I* into the reservoir *J*.

To assist the process, a partial vacuum is formed in the retorts by a pipe *E* on the Giffard injector principle. When all the oxygen capable of being extracted is liberated, the steam is shut off and a fresh portion of air admitted through an appropriate pipe; part of its oxygen combines with the exhausted manganate, forming a permanganate which is treated as before.

Archereau's apparatus comprises a cupola of fire clay, inclosed in a leaden shell within which sulphuric acid is decomposed by exposure to an extended heating surface formed by iron bars. The mingled sulphurous-acid gas and oxygen are passed

Fig 3459.



Archereau's Oxygen-Gas Apparatus.

through a washer, where part of the acid is absorbed, the remainder being condensed by passing through a worm in a condenser.

In the process of Du Motay and Maréchal, oxygen is derived from the reactions between sulphuric acid and the oxides of various metals, which readily part with a proportion of this gas and reabsorb it from the atmosphere: the sulphurous-acid gas and oxygen liberated by this process are passed through a vessel containing oxide or carbonate of magnesia, which is converted into a sulphite; this is decomposed by heating, and the sulphurous acid which escapes is converted into sulphuric by treating with steam, air or nitrous gas, the magnesian compound being again ready for use. The patent also embraces means for procuring oxygen by heating such compounds as permanganates, chromates, and ferrates, which are reoxidated at a lower temperature.

In Mallet's process, sub-chloride of copper is transformed by the air into an oxi-chloride, which parts with its oxygen when subjected to a red heat in rotating retorts lined with fire-clay. The oxi-chloride is mixed with 15 or 20 per cent of sand in the retorts. The oxygen passes through a washing-vessel to the gas-holder. Fresh oxygen is supplied to the contents of the retort by first cooling by jets of steam, and then forcing a current of air through it. For production of chlorine and oxygen at the same time, hydrochloric acid is injected in place of steam. According to the amount of acid injected oxi-chloride or pure chlorine may be evolved.

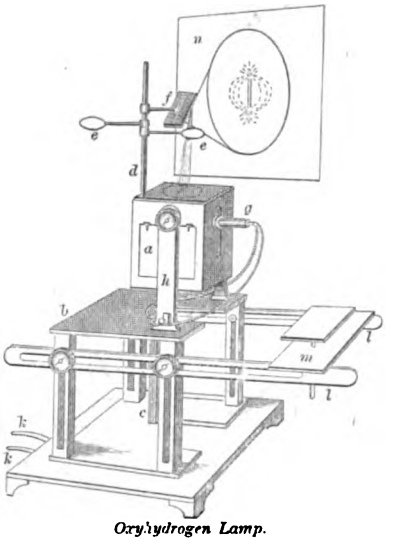
Digitized by Google

Ox-y-hy'dro-gen Blow'pipe. One used by mineralogists and chemists for reducing metallic ores in analyses. The flame is produced by the combustion of hydrogen gas in the presence of an atmosphere of oxygen, with which the combustible gas is mixed.

Ox-y-hy'dro-gen Lamp. One in which streams of oxygen and hydrogen in regulated quantities are commingled, the resulting flame being directed on a ball of quicklime and forming an extremely bright light; now used very largely by lecturers on science, to illustrate phenomena, and by exhibitors to project pictures upon a screen.

The body of the lantern *a* is swung between two uprights, to which it can be clamped firmly in any position required. The uprights are fastened in the top board of the stool *b*, which can be rotated in a horizontal plane round the upright tube *c*, to direct a beam of light in any direction. At one corner of the front plate is the bar *d*, carrying the lenses *e e* and the mirror *f*. These slide on the bar in the

Fig. 3460.



Oxyhydrogen Lamp.

same manner as the rings on a retort-stand, and can be turned out of use in a moment. The jet, the lower part of which is seen at *g*, slides through a collar working in the slit at the base of the lantern. The caoutchouc tubes from the jet pass through screw pinch tabs, one of which is seen on *h*, and then they pass through the tube and underneath the base-board, as seen at *k*. The cross-pieces *l l* serve to support a table *m*, on which apparatus, such as a prism, etc., can be supported. To show magnetic curves, cohesion figures, or anything which requires to be illuminated while in a horizontal position, the lantern is clamped in an upright position, shown in the figure. The glass plate with the magnet attached is laid over the condenser, and one or both lenses, according to the size of image wished, are brought into action. The mirror is then adjusted to throw the image on a vertical screen *n*. Should it be desired to direct a beam downward, as in showing the refraction of light, the lantern is clamped with the axial line of the lenses pointing obliquely downward. The mirror is either slipped off the bar or turned out of the way, the cross-pieces and tables being removed. For exhibiting ordinary lantern-slides or photographs, a clip is attached to the front of the lantern, the instrument clamped in a horizontal position, and the slides then exhibited in the usual manner.

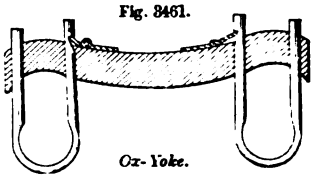
Ox-y-hy'dro-gen Light. A light of intense brilliancy produced by the combustion of lime in the flame of a combined jet of oxygen and hydrogen gases.

See CALCIUM-LIGHT; DRUMMOND-LIGHT.

Ox-y-hy'dro-gen Mi'cro-scope. A microscope in which the object is illuminated by the flame on a piece of lime or marble under the action of the compound blowpipe. The lime is placed in front of a concave mirror, and the object between this and a convex lens, by which its image, highly magnified, is thrown upon a screen so that it may be visible to any number of spectators at once.

Ox-yoke. The means whereby a steer is fastened to the tongue of the cart or wagon. It usually rests upon the neck, but the bar strapped to the forehead or poll goes by the same name. It is usually of the shape shown in Fig. 3461, and is held in place by bows.

Fig. 3461.

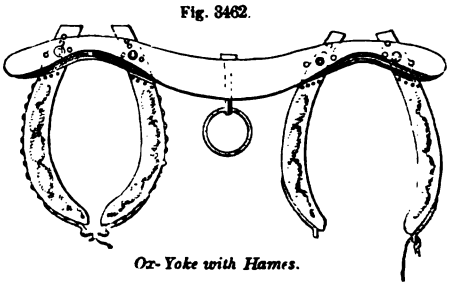


Ox-Yoke.

The bows are held in place by keys which pass through holes in the bows and rest upon the top of the yoke; or, as in the example, the hinged metallic plate engaging in a notch in the bow retains the same and obviates the use of a key.

Fig. 3462 shows a yoke with *hames* instead of bows. The hames are pivoted at their upper ends

Fig. 3462.



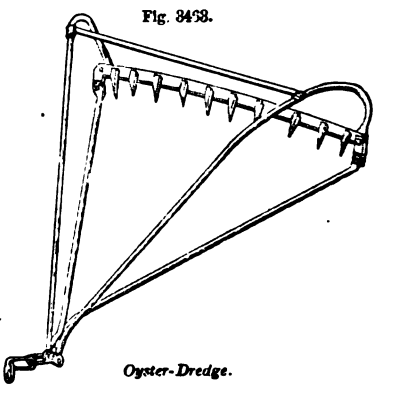
Ox-Yoke with Hames.

to the yoke, and fastened at the lower ends by straps.

See also YOKE.

Oys'ter-dredge. A rake and drag-net for gathering oysters from the beds. The dredge is

Fig. 3463.



Oyster-Dredge.

Digitized by Google

thrown overboard and dragged by a sail-boat over the oyster-beds. It is then hauled up by tackle and drawn on board over a roller on the gunwale of the boat.

A stout bag is fastened to trail behind the bow of the drag and catch the oysters upturned by the rake. See also DREDGE.

In olden times, the edible oyster was dived for, as the pearl-oysters now are.

"Oysters lie at the bottom of the sea, and one cannot get at them by any other means, except by diving to the bottom." — ATHENÆUS; EPIT., B. I. 22.

He also quotes Homer as saying, —

"An active man is he, and dives with ease"
(ILIAD, XVI. 745),

in reference to a man who gathered them fast enough to keep several persons supplied.

Epicharmus, in the "Marriage of Hebe," says: —

Bring "oysters with closed shells,
Which are very difficult to open, but very easy to eat."

The pearl-oyster of the Indian Ocean is mentioned by Theophrastus and Athenæus, who speak of it as a precious stone resembling a large fish's eye, and that expensive necklaces are made of them for the "Persians, Medes, and all Asiatics." Theophrastus says: —

"They are engendered in the flesh of the oyster, just as measles are in pork."

The oysters of Britain were highly esteemed by the epicures of the Roman Empire.

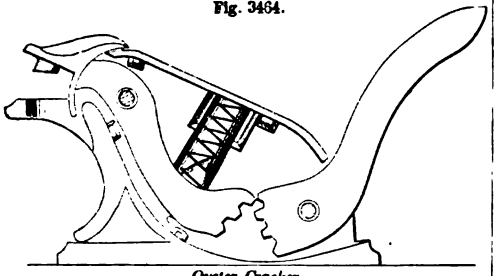
Oys'ter-knife. A strongly stocked and thick-bladed knife which is thrust between the shells of the bivalve, being a case of forcible entry. In America, the power of the mollusk is somewhat impaired by hammering upon the hinge, but in England the knife is driven between the shells without previously demoralizing the fortress.

Oys'ter-o'pen-er. An invention of Napier, England. The bivalve is laid on a stake and a notch taken out of the edge of the valves by a lever knife. It is then placed edgewise between a pair of knives, which are forced together and separate the shells.

Oys'ter-rake. One for raking up oysters from their beds. Usually dragged overboard by a sail-boat, and known as a *dredge*. See OYSTER-DREDGE.

Oys'ter-shell Crack'er. An implement for

Fig. 3464.



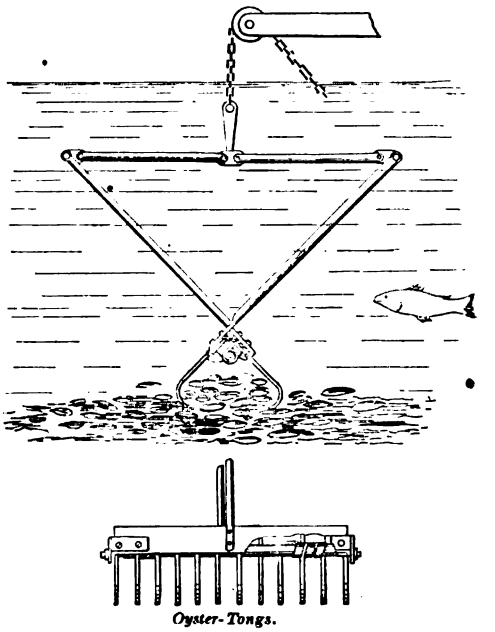
Oyster-Cracker.

breaking a notch in the shells of an oyster in order to facilitate entrance of the knife. The lower jaw is fixed and the upper one brought down by the lever and pivoted arm, which gear together.

Oys'ter-tongs. An instrument having two rake-shaped jaws and a pair of long handles, to grapple oysters in their beds and lift them to the surface.

On a large scale, as in Fig. 3465, the grappling-tongs are suspended over a beam rigged out from a boat, being held in extended position by a spring, and brought together by the action of raising, through

Fig. 3465.



Oyster-Tongs.

means of the toggle-rods. The head is sunk by a longitudinal bar to which the jaws are hinged.

O'zone-ap'pa-ra'tus. Ozone is an allotropic condition of oxygen, also called *active oxygen*. It has the property of decomposing iodide of potassium with liberation of iodine. Its odor led to its discovery by Schönbein in 1840, though the odor which oxygen acquires by the passage of the electric spark was noticed by Van Marum more than half a century previously. Van Marum also observed its power of attacking mercury. It perhaps may be considered as an instable and extremely active condition of oxygen, having a density 1½ times greater than ordinary oxygen.

Ozone may be obtained by placing a stick of freshly scraped phosphorus in a bottle filled with air and containing sufficient water to partially submerge the phosphorus; the vessel is then closed and kept at a heat of 60° to 70° Fah. for six or eight hours. It is also produced by passing the electric spark through oxygen gas in the electrolytic decomposition of water, and by the slow combustion of ether caused by plunging a heated glass rod into a vessel containing this substance.

According to O. Loew, ozone may be obtained by passing air through the flame of a Bunsen burner.

O-zo-nom'e-ter. An instrument invented by Moffatt, for ascertaining the amount of ozone in the atmosphere.

Paper or linen, imbued with a mixture of iodide of potassium and starch, is used.

A slip of paper so prepared is placed in a current of air and protected from rain, light, and foul effluvia for a period of from six to twenty-four hours. By exposure the paper becomes brown, and when wetted acquires shades of color varying from a pinkish-white and iron-gray to a blue. The paper is compared with a prepared chromatic scale.

Digitized by Google

P.

Pac; Pack. A moccasin having a sole turned up and sewed to the upper. Though now made of leather of various kinds, the *pac*, as used by the Indians of the Six Nations, for instance, was made of hide boiled in tallow and wax; or of *tawed* hide subsequently stuffed with tallow or wax.

Pach-om'e-ter. An instrument for measuring the thickness of the glass of mirrors.

Pack. 1. (*Coopering.*) The staves and headings of a cask hooped up in a compact bundle for transportation. A *shook*.

2. A pile or bundle of sheet-iron plates, for heating or rolling simultaneously.

Pack'ag-ing-ma-chine'. A machine for bundling yarns or goods into compact shape for transportation. A *bundling-press*.

Pack-cloth. Coarse baling material: hemp, jute, etc. *Gunny-cloth*.

Pack'et. (*Nautical.*) *a.* A mail or passenger vessel plying between port and port at regular times.

b. A vessel employed in carrying letters.

Pack'et-note. 1. A folded writing-paper, 9 × 11 inches, half the size of *packet-post*.

2. A size of note-paper.

Pack'fong. (*Alloy.*) A Chinese alloy known as white copper. Copper, 40.4; zinc, 25.4; nickel, 31.6. See ALLOY.

Pack'ing. 1. A contrivance or a material to close a joint. See PISTON; PISTON-PACKING.

In the atmospheric engines of Papin, Savary, and Newcomen, the piston was packed air-tight by means of flooding its upper surface with water. Watt obtained a patent for packing pistons with lubricators instead of water, 1769.

The piston-rod is also packed in its stuffing-box.

Various greasy materials with gaskets, oakum, etc., are used in joints which are screwed down; also collars of rubber, red-lead, luting. Flues and tubes are closed into the flue-sheets or tube-sheets by riveting. Tubes of condensers by thimbles, screw-joints, or preferably by Horatio Allen's collars of pine, which swell and close the joint but allow expansion and contraction.

2. (*Masonry.*) The filling in of a hollow or double wall.

3. Air-tight joints for fruit or jam can-covers are made by screwing or clamping the covers upon a gasket of rubber; or wax or resin is run into a crevice. See FRUIT-JAR.

Fig. 3466.

Packing-Awl.

4. Well-tubes are packed by rubber thimbles, inflatable bags filled with air or water, or with flaxseed, which swells as it absorbs water.

Pack'ing-awl. One for thrusting a twine through a packing cloth or the meshes of a hamper, in order to fasten the package by a tie.

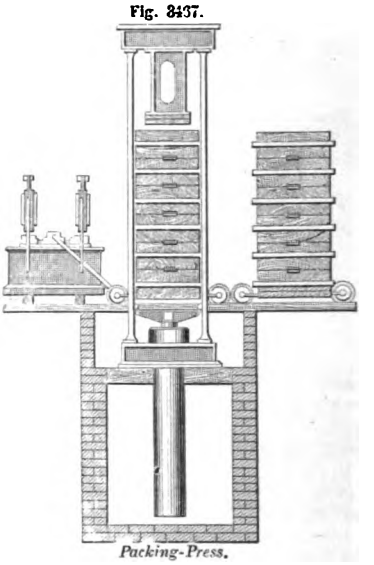
Pack'ing-bolt. (*Steam-engine.*) A bolt which secures the gland of a stuffing-box.

Pack'ing-box. 1. (*Steam-engine.*) A steam-tight composition or systems of parts around the piston-rod of an engine where it passes through the head. A *stuffing-box*.

2. A box for transportation of merchandise.

Pack'ing-press. A press for baling cotton, wool, hay, etc. The power, screw, or preferably hydraulic, is applied to the platen from beneath, and the boxes in which the substance is compressed are provided with hinges and catches so as to be readily taken apart; these are placed one above another on trucks with rollers, which are run under the press for compression,

Fig. 3467.

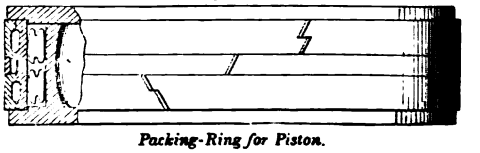


Packing-Press.

and withdrawn when the operation is finished. See BALING-PRESS.

Pack'ing-ring. (*Steam-engine.*) A ring on a piston to expand against the inside of a cylinder and prevent passage of steam. The example shows a set of three rings in which the transverse joints are kept tight by an intermediate ring with inclined edges so fitted between two packing-rings as to

Fig 3468.



Packing-Ring for Piston.

wedge them against the heads of the piston, and pressed outward only by the contact of the packing-rings, the latter being expanded by customary springs. See PISTON; PISTON-PACKING.

Pack'ing-stick. A *woolding* stick; one used in straining a twine around a rolled fleece of wool in tying.

Pack-sad'dle. One constructed for a pack or sumpter animal. It is provided with hooks, rings, and straps to support baggage, stores, or rations.

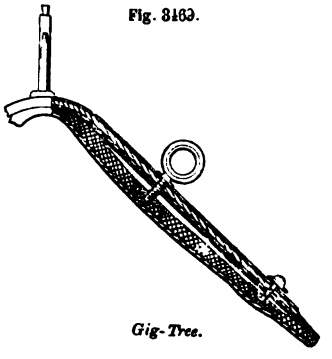
The pack-saddle for mountain artillery is adapted for transporting a light howitzer, with its carriage and ammunition, when the country is too rough for the passage of vehicles. For this purpose the front and rear of the saddle are made high, and in the form of arcs of a circle, and are recessed so as to readily receive the howitzer, which is lashed on the

Digitized by Google

saddle, muzzle to the front. The shafts of the carriage are also lashed on the same saddle, the crossbar resting on the cascabel of the howitzer. The carriage and wheels are carried on a similar saddle upon the back of another mule. The chests containing ammunition are carried by a third animal, one chest being suspended on each side of the saddle. See SADDLE.

Pad. 1. (*Menage.*) *a.* A cushion or stuffing, as that beneath a saddle, to keep the *tree* from galling the horse's back.

Fig. 3469.



Gig-Tree.

b. A cushion beneath a gig-tree of carriage harness, as in Fig. 3469.

c. A saddle without a tree.

d. That part of a double harness to which the girths are attached; used in place of the gig-saddle.

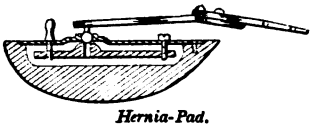
e. A cap of leather, stuffed, buckled over the knee, to keep that part from being grazed or injured by an occasional fall. See LEG AND FOOT GUARDS FOR HORSES.

2. (*Shipbuilding.*) A piece laid over a ship's beam to give the camber.

3. (*Dyeing.*) To impregnate with a mordant.

4. (*Stationery.*) A soft writing surface, as a quarter-quire of blotting-paper, for instance. A *writing-pad.*

Fig. 3470.



Hernia-Pad.

5. (*Surgical.*) *a.* The bag or knob of a truss which rests upon a hernial tumor and prevents its projection.

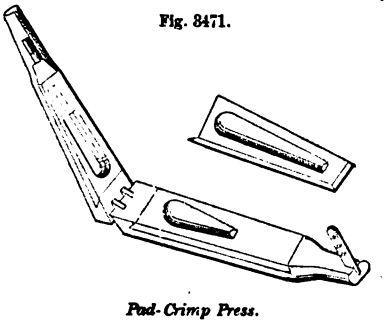
b. A bag or cushion to compress or support a part.

c. A soft wad between the splints and a fractured limb to prevent chafing.

Pad-cloth. A housing-cloth, extending over the horse's loins.

Pad-crimp Press. (*Harness.*) A press in which dampened leather is pressed into shape between protruding and hollow parts of a former. The respective portions are connected by a hinge, drawn forcibly together, pressing the piece of leather into shape, and are thus locked until the leather is dry enough to retain the shape of the mold.

Fig. 3471.



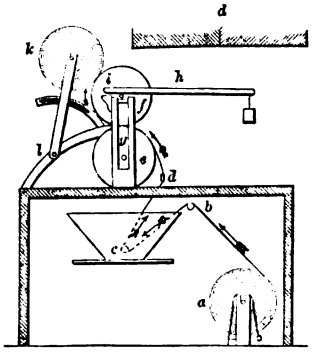
Pad-Crimp Press.

Pad'ding. 1. A method of calico-printing in which the whole surface of the cloth is imbued with a mordant, upon which different colored figures are subsequently raised, by the topical application of other mordants, joined to the action of the dye-bath. Also known as the *plaquage* style.

2. A cloth worked out of rags for stuffing collars of coats, etc.

Pad'ding-ma-chine'. (*Calico-printing.*) An apparatus for uniformly imbuing cotton cloth with a mordant in the process of dyeing.

Fig. 3472.



Padding-Machine.

The cloth is wound upon the roller *a*, and is kept tense by a weight passing over a pulley on its axis, and by the roller *b*. It passes through the dye-trough, under the roller *c*, and is pressed against the half-round stretcher-bar *d*, the face of which has diverging grooves which stretch and smooth the cloth previous to its entry between the cylinders *e f*, which are covered with several thicknesses of cotton cloth. The journals of the roller *e* are fixed in the upright standards *g* on either side, while those of *f* admit of vertical movement so that its pressure may be varied by the adjustment of the weighted lever *h*, which is fulcrumed at *i*. The cloth passes obliquely between these cylinders, and is finally wound upon the roller *k* journaled in standards pivotally supported in the arc *l*, so as to allow for increase of size as the cloth winds upon the roller.

Pad'dle. 1. The water-door in a lock-gate or sluice. A *clough.*

2. A float or board of a paddle-wheel.

3. A small scull for propelling a boat or canoe. A short oar, used without being shipped in a rowlock.

4. An iron bar or blade for stirring ore in a furnace.

5. A bat or pallet for working in plastic material.

6. A shovel or scoop to stir and mix materials, as sand with ashes in glass-making.

Pad'dle-box. (*Nautical.*) The upper case of a steamboat's paddle-wheel.

Pad'dle-box Boat. A boat which forms the upper section of the paddle-box, and is launched in case of emergency.

The paddle-box boat of Captain Smith of the English navy forms the top of the wheel-house in its ordinary capacity, being of a size adapted to its position and the size of the wheel. In the "Carron," 250 tons burden, it is 25 feet long, 9 feet beam, and has 4 air-tight cases, which qualify it as a life-boat. When in place, as the roof of the wheel-house, the midship thwarts are unshipped, so as not to be struck by the paddle-wheel, which revolves within six inches of her keelson.

One of the figures shows the boat in position, and the other is a transverse section of the vessel, showing the boat on one side of the vessel, turned over, suspended from the davits, and ready for lowering.

The boat lies bottom upwards on two iron davits having hinges, which enable her to be turned over

Digitized by Google

and lowered down by six men in three minutes. A boat of similar capacity (capable of containing 40 to 50 men) could not be got out, if stowed in the usual position on deck, under twenty minutes, by

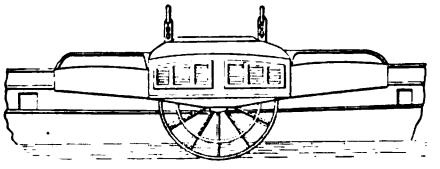


Fig. 3473.

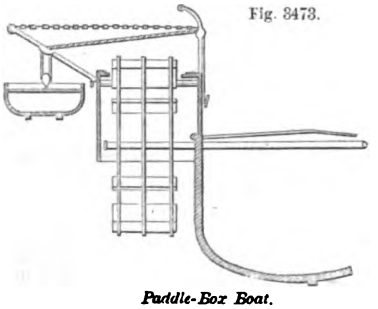


Paddle-Box Boat.

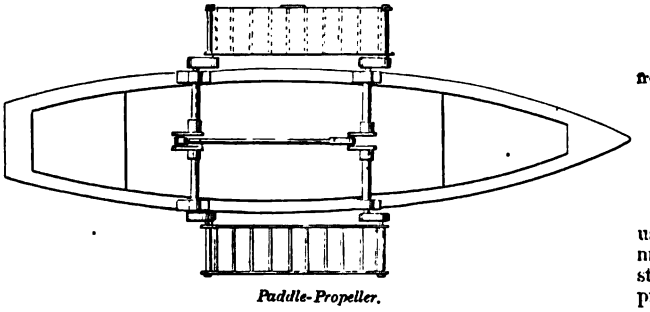
the whole crew; and, in case of fire, probably not at all.

The longitudinal view shows the cabins, cook-houses, etc., before and abaft the wheel-house, similarly covered in.

Pad'dle-hole. (*Hydraulic Engineering.*) A water-channel through which the water passes from the upper pond of a canal to the lock-chamber, or from the latter to the lower pond.

Pad'dle-pro-pel'ler. A form of boat propulsion in which the vertical blades are bolted to a parallel bar and connected to cranks, by whose revolution they are alternately immersed to make the effective stroke and raised clear of the water on the return stroke.

Fig. 3474.



Paddle-Propeller.

Pad'dle-wheel. A water-wheel used in the propulsion of a vessel.

The framework of a paddle-wheel consists of *centers*, *arms*, and *rings*.

The *centers* are *disks* or *bosses*, two or three in number, keyed around the paddle-shaft and having sockets around their rims for the arms.

From each of the *centers* there radiates a set of *arms*, equal in number to the paddles. The *arms* are straight, flat iron bars, so placed as to move edgeways through the water. The outer ends of the arms are T-shaped, and to the cross-bars of each set of arms is riveted an outer *ring* of bar-iron. Inner rings, one or two in number to each set of arms, are riveted to lugs, or projections from the edges of the arms.

The proportions given by Hebert are to make the diameter of the wheel equal to four times the length of the stroke, and the depth of each paddle ⅛ of the diameter.

The first use of paddle-wheels may have been in the *velocimeters* of the ancients, in which an axis crossed the vessel, projecting over each side, and had paddle-wheels four feet in diameter, which dipped into the water and were rotated by the progress of the vessel. A tooth on the axis worked a train of gearing, so as to drop a ball at every 400th revolution of the paddle-wheel, indicating by sound and count the distance traveled.

Jonathan Hull, in his English patent of December 21, 1736, describes his boat as driven by a fire-engine, meaning a Newcomen atmospheric engine, which rotated "six fanns that turn upon an axis, ... the fanns are brought into and keep a direct motion in the water which forces forward the vessell in which the machine [steam-engine] is placed."

The paddle-wheel has been a favorite subject with inventors, the aim having been to enable it to enter the water without percussion and to leave it without raising a swell.

The greater number of these devices are for feathering the paddles, a subject which belongs to Division 2 (see below).

Some of these devices may be considered under this head, and it may be here stated that the loss of power incident to the obliquity of the blow delivered by the paddle is much exaggerated.

Galloway's patent, 1835, specifies paddles of cycloidal form, which enter the water nearly vertically and avoid concussion. They would probably lift the water when emerging worse than the common float.

Paddle-wheels may be classed under nine different heads: —

1. Floats fixed on the arms.
2. Feathering floats.
   a. Turning on horizontal axes.
   b. Turning on radial axes
3. Floats sliding radially toward and from the paddle-wheel shaft.
4. Floats attached to traversing chains.
5. Floats attached to cranks.
6. Collapsing paddles.
7. Floats in reciprocating frames.
8. Sculling paddles.
9. Cycloidal paddles.

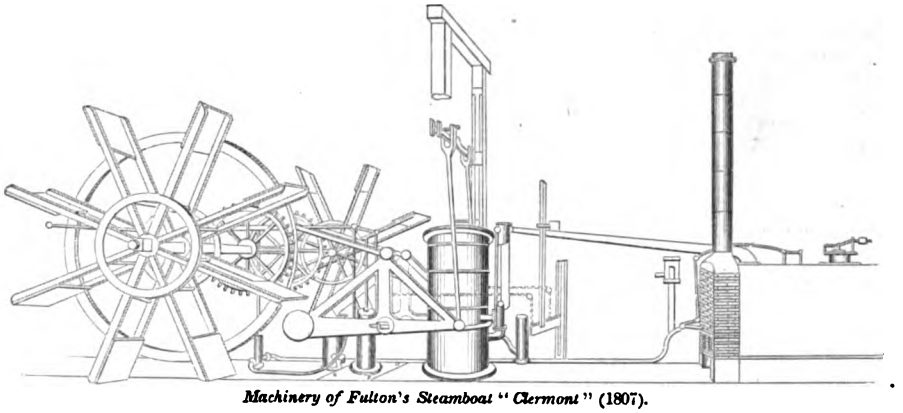
Fig. 3475 shows the paddle-wheel used by Fulton on the "Clermont" in 1807. This was the first steamboat which can be called a practical success, she having made regular trips between New York and Albany for several years. The paddle-wheel used by Fulton is of substantially the same form as the one now in general use. See Woodcroft's "History of Steam Navigation."

Gemmel's patent, 1837, is rather a duplication than a change of construction. Two pairs of paddle-wheels are employed, the horizontal steam-cylinders having piston-rods proceeding from each end, and having cross-heads from which connecting rods reach to the paddle-wheel shafts.

2. *a.* Buchanan's parallel float-wheel. The floats are attached to horizontal shafts which have their bearings in the radial arms. On the axis of each paddle is an arm from which a rod proceeds to an eccentric on the paddle-wheel shaft. The effect is

Digitized by Google

Fig. 3475.



Machinery of Fulton's Steamboat "Clermont" (1807).

to keep the floats vertical at all points of their revolution.

In Galloway's patent of 1829 the revolution of the wheel causes an eccentric collar to rotate by the action of arms, and the radius rods cause each paddle to oscillate on its axis so as to enter and leave the water obliquely.

In Oldham's improvement in 1827, the angle of the paddles is constantly varying, being vertical only at the point of greatest submergence, and horizontal at the point of greatest elevation. The change of position is accomplished by the oscillation of the axis of the float, by means of rods, cranks, and an eccentric wheel on the paddle-shaft.

b. Dawson's feathering paddle-wheel (*A*, Fig. 3476), 1814, has floats attached to radial rods which rotate on their axes so as to enter and leave the water obliquely, but present their full surfaces squarely at the point of greatest immersion. The change is effected by affixing on the axis of each paddle two wipers which cross each other at right angles, the wipers coming in contact with inclined planes which cause the axes to oscillate to the extent of 90°.

Head's improvement, 1828, has two leaves to each float; these open so as not to oppose the action in entering and leaving the water, but during immersion form a combined broad float.

3. Leeming's sliding float (*B*), 1835. The arms are grooved and the paddle-boards slip out and in by the action of an eccentric *c* attached to the side of the vessel.

After its effective stroke each paddle is withdrawn nearly vertically.

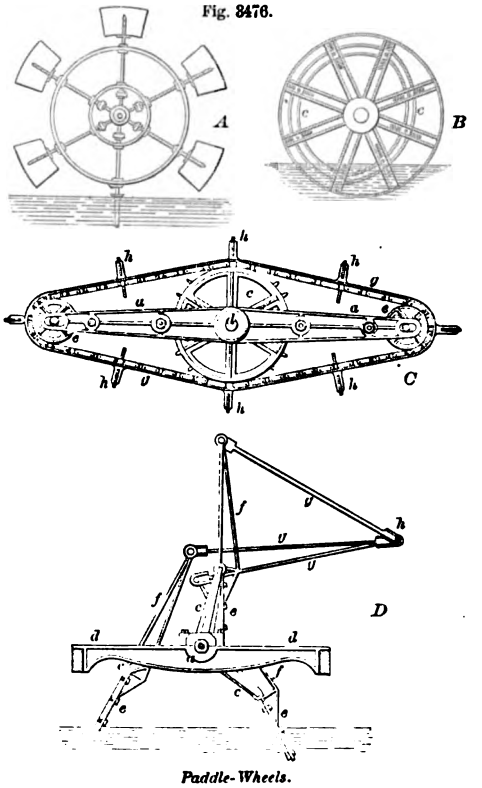
4. Floats attached to endless chains which pass over drums have been used, the intention being to give a direct impulse in the line of the vessel's motion, instead of giving the oblique blow upon the water incident to the ordinary paddle-wheel.

Spurgin's endless-chain propeller (*C*), 1837, passes over three wheels, the larger one being spiked and forming the driving-wheel, while the end wheels are drums which extend the chain and maintain its position; the middle wheel being larger, or having an axis depressed below those of the drums, so as to give a certain obliquity to the floats in entering and emerging.

a a is a cast-iron frame bolted to the side of the vessel; *c* is one of a pair of spike-wheels fixed on the engine-shaft *d*; *e e* are drums running upon the pins or studs on the ends of the frame; *g g* is an endless flat chain passing over the drums *e e*, and over and under the spike-wheel *c*. In order to keep this chain extended, the axes of the drums *e e* move in slots in the frame *a a*, and are keyed up so as to give the requisite tension to the chain. *h h* are the floats, which are carried by iron forks, which are forged in one with the middle links which support them.

5. Stevens's crank-axle paddle (*D*) (English), 1828, has three paddles attached separately to the arms of a three-throw crank, and, by means of radius and

Fig. 3476.



Paddle-Wheels.

guiding-rods connected with them, the paddles are each made to describe in the water the segment of an ellipse.

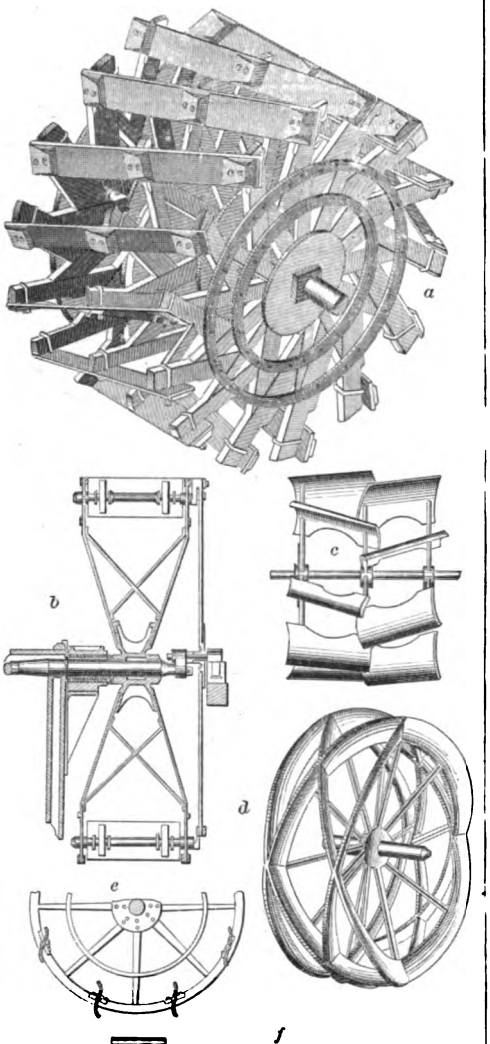
a is the axis of a triple crank, the separate arms of which *c c c* move between parallel bars on the side-frame *d d* of the paddle-box. *e e e* are the three paddles connected by the guide-rods *f f f* to the radius-rods *g g g*, the latter working from a fixed beam or center *h*.

Digitized by Google

6. Nairn's collapsing paddle (English patent, 1828) is allied in principle to the duck's-foot propeller. A number of levers are suspended over the sides of the vessel, extending to any suitable depth. These are made to vibrate by means of the engine, and the feet or paddles on the levers are made to collapse during the non-effective stroke, so as to offer no resistance; but when the effective stroke is made, the float expands, offers its full area to the water, and propels the vessel.

The *duck's-foot* propeller was tried by a Swiss clergyman, named Genevois, about 1737. It was

Fig. 3477



Paddle-Wheels.

of a contracting and expanding character, and was intended to resemble a duck's foot in its mode of operation. Earl Stanhope revived the idea about 1803.

7. Floats in reciprocating frames. A number of vertical floats are arranged in a frame which moves in one set of horizontal guides while making its effective stroke, the paddles being submerged or nearly so. At the end of its stroke it is lifted out of the water, returned along an upper track, dropped down to its work, and then again propelled.

A number of patents have been granted for modifications of this general idea.

8. Perkins's sculling-wheel, patented in England in 1829, has paddles set obliquely on radial arms which are attached to axes sloping toward the stern, so as to make with the axis of the vessel angles of 45° and an angle of 90° with each other. On the extremities of the axis are bevel-wheels, which are both acted upon by an intermediate wheel driven by the engine.

In Fig. 3477, *a* shows a form of paddle-wheel so constructed that the blades descend obliquely into the water, so that an equal amount of blade-surface is submerged at all times and jar avoided. The position of the arms gives the blades such direction as to prevent them from lifting water.

Feathering paddles are of various forms. The object of feathering the floats is to present them to the water at right angles at all times, and to cause them to enter and leave the water edgewise.

In *b*, Fig. 3477, the floats are operated by rods from an eccentric on the crank-shaft. The crank connection between the controlling frame and guard-beam permits the bearing of the controlling frame to change its position in relation to the guard-beam whenever the latter changes its position in relation to the main wheel. In consequence of the diagonal arrangement of said connection, the controlling frame is moved to the least extent by movements of the paddle-guard in vertical and horizontal directions. The arrangement of the paddle-cranks is intended to equally divide the weight of the controlling frame between the paddle-wheel and the paddle-wheel guard.

c, same figure, gives another form of wheel constructed with the same object in view. The floats are curved as well as set diagonally to the shaft.

d is a form of oblique paddle designed to avoid jar.

e has feathering paddles automatically operated by the pressure of water against them.

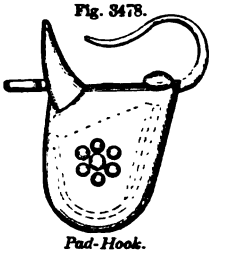
f shows the paddle within the hull, adapted to canal-boat propulsion.

The paddle-wheels of the "Great Eastern" are 56 feet diameter, 13 feet deep, 30 floats or paddles.

Pad'e-soy. (*Fabric.*) See PADUASOY.

Pad-hook. (*Saddlery.*) A hook on the back-pad to hold up the bearing-rein.

Fig. 3478.



Pad-Hook.

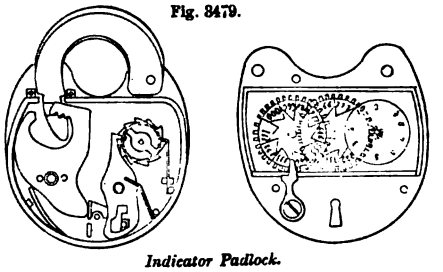
Pad'lock. A lock with a bow to hold on to a staple. Made by Bechar at Nuremberg, A. D. 1540. Dr. Abbott's collection of Egyptian antiquities in New York contains a padlock found in a tomb at Sakkarah. They were also used by the Romans.

Fig. 3479 is an example of one in which the key, on being inserted, acts first on the tumblers, so as to free the cylinder and to allow a slide to be raised, and it then raises the slide so as to turn the cylinder. The slide-bolt is replaced in its original position by the turning back of the key after the lock has been opened.

Fig. 3480 is a combination padlock having a number of disks which must be brought into coincidence to allow the bolt to be withdrawn from the hasp. The disks are numbered on their peripheries, and

Digitized by Google

Fig. 3479.

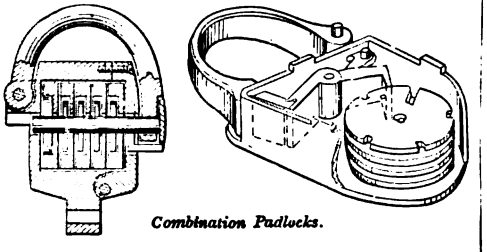


Indicator Padlock.

perforated with central holes and radiating slots for the passage of the bolt. The bolt has an axial bar and radial arms. The arms having passed through the slots in the disks, the latter are disarranged and oppose the withdrawal of the bolt. A screw under the shackle fastens the lid, which may be opened to remove and rearrange the disks.

Fig. 3481 is a perspective view of another combi-

Fig. 3480. Fig. 3481.



Combination Padlocks.

nation lock. In closing the hasp its shank acts against the lock-bolt and interlocks with the latter while withdrawing its dog from the gateways of the tumblers; hence, in order to lock the hasp, it is only necessary to break up the combination by turning a thumb-screw.

Pad-plate. (*Harness.*) An iron bow, either malleable or wrought, upon which the pad is made, answering the double purpose of giving stiffness to the pad and as a means of attaching the mountings.

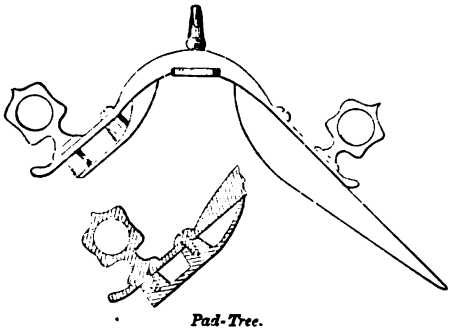
Pad-sad'dle. (*Harness.*) A saddle made of leather and padding without any *tree*.

Pad-screw. (*Harness.*) *a.* A screw-bolt having an ornamental head, used for securing the pad-sides to the pad-plate, and as an ornament.

b. A screw to hold the *tug-strap* and *gig-flat* together.

Pad-side. (*Harness.*) The strip of leather attached to the end of the pad, which furnishes a portion of the girth to hold the latter in its place.

Fig. 3482.



Pad-Tree.

Pad-top. (*Harness.*) The ornamental leather that forms the top or finish to the pad.

Pad-trace Bear'er. (*Harness.*) A strap attached to the outside of the pad-side under the end of the pad-top, and extending down outside the pad-side to permit the trace passing between it and the side; used in double harness only.

Pad-tree. (*Harness.*) A piece of wood or metal which gives shape and rigidity to the harness-pad.

Pad-u-a-soy'. (*Fabric.*) A kind of silk.

Pæ-dom'e-ter. An instrument for measuring the length of children.

Page. 1. One side of a leaf in a book.

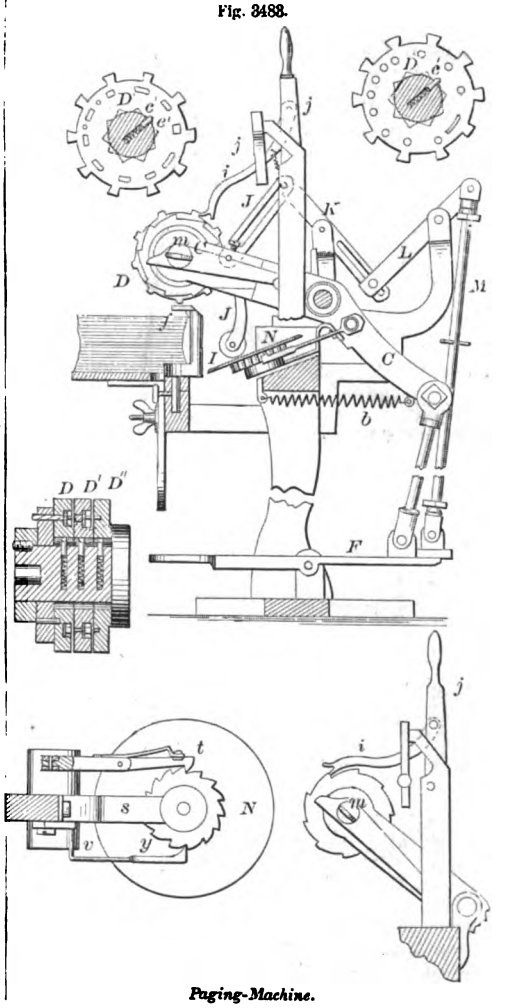
2. The track carrying the pallets, which support the newly molded bricks, and on which they are slipped to the off-bearing boy who stands at the end. See BRICK.

Page-cord. (*Printing.*) Strong, smooth cord, cut in suitable lengths to tie up a page of type. It is wound three or four times about the type, and the ends tucked under, not tied.

Page-gage. (*Printing.*) A standard of length for the pages of a given piece of work, to keep them uniform.

Pag'ing-ma-chine'. (*Printing.*) A machine

Fig. 3488.



Paging-Machine.

Digitized by Google

for giving the consecutive numbers to the pages of an account or blank book. Also used, under the name of a *numbering-machine*, for giving the successive numbers to tickets, cards, checks, etc.

In one form the numbers are presented on disks which combine to form a cylinder. This is driven down upon the paper, delivering an impression. The unit-wheel is then turned a notch, which shifts the number one point, and another impression is given. The numbered disks are connected in series, as in REGISTERS, ARITHMOMETERS, GAS-METERS, etc. (which see).

Fig. 3483 shows a common form of paging-machine for printing the same number or a succession of numbers on sheets or leaves which are fed to it. The figures are on the circumference of disks *D*. These are mounted on shaft *m* in such a manner that they revolve independently of it. The disks are held above the paper *f* by the force of a coiled spring *b* at the other end of pivoted arm *C*. Pressure of the foot upon the treadle end of lever *F* brings down the face of the type on the sheet, and at the same time throws back the inking-roller *I* upon the ink-distributing disk *N*. When the pressure upon the treadle ceases, the type-disks rise, and the inking-roller passes across their lower face by the action of toggle levers *J K*, *L M*. The figure on the units disk is at the same time shifted by the pawl *i*, operated by lever *j*, acting on the ratchet-wheel, or this part may be thrown out of gear and the same number retained. Each revolution of the units disk moves forward the tens disk one figure, and so on.

The ink distribution is effected by the revolution of disk *N* through the mechanism *s t v y*, shown in one of the detached figures.

Disks *D D' D''* may be shifted to the extent of two figures when it is desired to have a series of alternate figures, as in paging the right or left hand pages of a book.

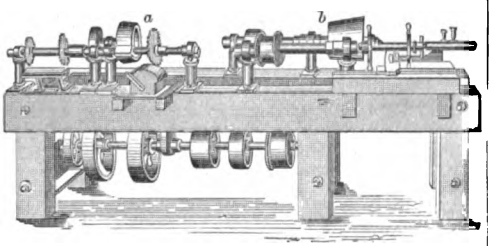
The disks are held in their places by a catch working in notches *c'*. An extra notch *c'* is provided, not in line with any figure of the disk, by which means the latter may be held to such a position that none of its type will print.

By the use of a machine of this class, an expert can number the pages in a book as rapidly as the leaves can be turned. The mechanical adjustment of the figures insures extreme accuracy in numbering a series of papers.

Pail-lasse'. An under-bed of straw. The form and purpose being retained, other materials have been substituted, as moss, finely shredded wood, called *excelsior*, corn-husks, sponge, hair. A *mattress*.

Pail-lathe. One in which buckets are turned on the outer and inner sides and the ends trued, dressed, and the croze made. The lathe shown in Fig. 3484 has two portions, *a* and *b*. The staves for a pail being assembled and held by a truss-hoop, the pail is placed on the chuck *a*, while the outside is turned off smooth and one end dressed, the hoop

Fig. 3484.



Fay's Pail-Lathe.

being shifted once so as to reach the whole surface. The pail thus dressed on the outside and one end is then stuck into the hollow chuck *b*, which holds it while the inside is turned smooth and the other end shaped and dressed. Operating on each end of head *a* are circular saws, whose distance apart is equal to the hight of the pail, and these act simultaneously, to saw off the ends.

Pail-ma-chine'. A bucket-making machine. See PAIL-LATHE.

Pail-nail. A kind of nail used in making some kinds of buckets.

Paint. 1. A pigment, white or colored.

The colors used by painters are principally derived from the mineral kingdom, though animal and vegetable substances are to some extent employed. The following tabular statement indicates the composition of those most generally used.

	Name.	Composition or Derivation.
WHITE.	White lead	Carbonate of lead.
	Zinc white	Oxide of zinc.
	Spanish white	Purified carbonate of lime.
	Sulphate of baryta	
YELLOW.	Yellow ochre	An earth composed of silica and alumina, colored by oxide of iron.
	Naples yellow	Antimoniate of lead.
	Chrome yellow	An impure chromate of lead.
	Gamboge	A gum principally derived from Siam.
BLUE.	Ultramarine	From *lapis lazuli*; also prepared artificially.
	Cobalt blue	Phosphate of alumina and oxide of cobalt mixed with arsenite of cobalt.
	Smalt-Saxon blue	Double silicate of cobalt and potassa, mixed with earthy and metallic oxides.
	Antwerp blue	Prussian blue with various proportions of alumina and carbonates of magnesia and zinc.
	Prussian blue	Ferro-cyanide of iron.
	Berlin blue	
	Indigo	From plants of the genera *indigofera*, *isatis*, and *nerium*, principally the former.
BLACK.	Lampblack	Carbon from the soot of burning rosin or other vegetable or animal matters.
	Ivory black	Calcined wine lees.
RED.	Red ochre	From calcination of yellow ochre.
	Red lead or minium	A mixture of protoxide and binoxide of lead.
	Madder	From the madder plant, *rubia tinctoria*.
	Cochineal	The dried bodies of the cochineal insect.
	Vermilion	Cinnabar, a sulphide of mercury, natural or prepared.
GREEN.	Chrome green	Sesquioxide of chromium.
	Schweinfurt green	Acetate and arsenite of copper.
	Scheele's green	Arsenite of copper.
	Verdigris	Acetate of copper.
BROWN.	Terra di Sienna	A natural earth found in the vicinity of Sienna, Italy; when burned it forms a red.
	Umber	An earth from that part of Italy anciently forming the Roman province of Umbria.
	Bistre	Soot of wood, preferably beech.

Numerous other colors are used by artists for producing different shades, and a large list might be made of those employed in dyeing and paper-staining, each having its peculiar fitness for special purposes. Among these, the various shades of violet, blue, green, red, etc., derived from aniline, a product of petroleum, have of late years assumed great importance. See ANILINE-COLORS; DYEING; WATER-COLORS.

2. (*Rubber-manufacture.*) Stuff mixed with caoutchouc in the process of manufacture, and intended to harden it. Sulphate of zinc, whiting, plaster-of-paris, lampblack, pitch, and other materials are used.

Paint-brush. Paint-brushes are generally made of hogs' bristles, but for artistic purposes the hair of other animals, as the fitch, badger, sable, and camel, is employed. Paint-brushes are commonly either round or elliptical in cross-section; the latter

Digitized by Google

are usually made of the best bristles, and are termed varnish-brushes.

In one method of attachment the handle is round, and its enlarged base has a prong on each side between which the thick ends of the bristles are inserted, and afterward secured by a wrapping of twine which is coated with glue mixed with red-lead.

Another way is to insert the tapering handle, around which the bristles have been previously fastened by wrapping, into a metallic cap; the handle is then driven home, so as to firmly hold the bristles between it and the cap.

Smaller brushes of this kind are known as sash-tools, fitches, lettering-brushes, etc., according to size, shape, or material. Graining-brushes, called blenders, are made of camel's hair, and are flat in shape.

James Watt recommended rats' whiskers as the best material.

Various other modes of securing the bristles have been tried.

In Fig. 3485, the metallic top has upper and under sockets, in the former of which the handle is inserted. The latter contains the bristles, which are held in place by a wedge *D* drawn upward by a screw, which also serves to secure the handle.

Fig. 3485.

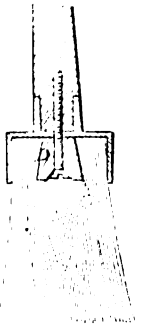


Fig. 3486.

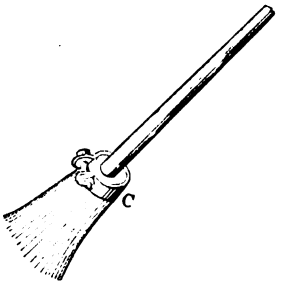
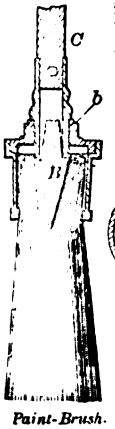


Paint-Brushes.

In Fig. 3486 the bristles are secured between the butt of the handle and an open ring *C*, the ends of which are drawn together by a screw passing through two lugs.

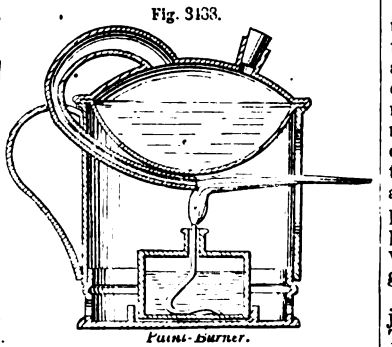
Fig. 3487.

In Fig. 3487, the end of handle *C* is provided with a screw-thread, and is made hollow to receive the shouldered wedge *B*; the bristles being inserted in the tubular top *b*, the wedge is forced in between them by screwing the handle *C* into place, causing them to be firmly retained between the wedge and the outer tube.



Paint-Brush.

Fig. 3488.

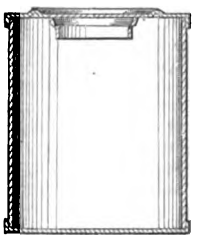


Paint-Burner.

Paint-burn'er. A blowpipe and lamp by which a flame is directed upon paint, to burn it off and prepare the surface for a new coat. In the example, the alcohol furnishing the vapor for the blowpipe is contained in the retort above the lamp.

Paint-can. A can specially constructed for holding paint. For convenience, paint is usually sold in cans of given capacity, and ingenuity is exercised in devising means for cheaply and securely closing, enabling them to be readily opened and conveniently used as paint-pots. Fig. 3489 has a removable cap.

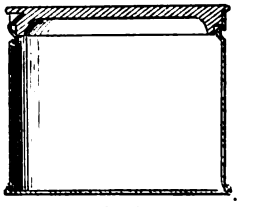
Fig. 3489.



Paint-Can.

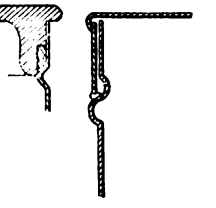
Fig. 3490 has an inwardly projecting bead to hold the gasket on which the cover rests. The cover has notches into which the rim of the metallic can is pressed to fasten the cover.

Fig 3490.



Paint-Can.

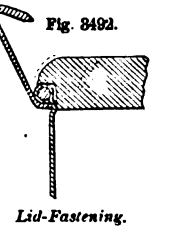
Fig. 3491.



Can-Lid.

In Fig. 3491, the can has protruding and intruding circumferential heads. The rim of the cover fits down over the latter and forms an air-tight closure; being cut around at that level, it subsequently forms a lid.

Fig. 3492.



Lid-Fastening.

In Fig. 3492, the hooks are soldered to the upper part of the can and turned over, so as to penetrate and hold the wooden cover.

Paint'er. (*Nautical.*) *a.* The bow rope which fastens a boat to a wharf or alongside a ship. *b.* A rope by which the shank of an anchor is secured to the gunwale. It is made partly of chain. A *shank-painter.*

Paint'ing. (*Fine Arts.*) The art of covering surfaces with pigments for decoration and protection; also the representation of objects in their natural colors by similar means.

In house-painting, the pigment most extensively used is white-lead. This is white, but it may be tinged with other ingredients to form grays, blues, and yellows of various shades, as well as many other colors. Zinc-white is also largely used, but does not possess the "body" of white-lead, requiring more to cover a given surface. Ochres and other earthy minerals are employed for forming different tints, of yellow, brown, and dull red. Other oxides and salts of lead, mercury, chromium, iron, and copper, form reds, greens, blues, and yellows. The impalpable powders derived from the smoke of some vegetable and animal products constitute different grades of blacks. See PAINT.

Any intermediate tints may be produced by the judicious intermingling of these principal colors. These are mixed with linseed-oil, either raw or boiled, to which, for most purposes, a greater or less proportion of spirits of turpentine is added. Rapid drying is insured by the addition of a small proportion of litharge, sugar of lead, or Japan varnish, according to material or color.

Painting as a fine art probably originated at even

Digitized by Google

an earlier period than its employment for preservative purposes, having been derived from the practice, almost coëval with the introduction of man on the earth, of sketching the outlines of animals and other objects on hard substances; outline drawings of the extinct elephant and rhinoceros having been found engraven on bone in caverns, the condition and contents of which indicate that in some parts of Europe they were contemporaneous with man at a period prior to the glacial era. From outline to monochromatic painting was but a step; shading, to produce the appearance of relief in rounded and projecting parts, and the employment of differently colored substances to imitate their natural hues, gradually followed.

The ancient Egyptians appear to have never advanced beyond the last step, shading having been unknown until introduced by the Greeks, whose esthetic minds improved and beautified every art which they borrowed from others. Such of their works as remain do not enable us to judge how far their knowledge of perspective had advanced, but it does not seem to have been reduced to an exact and systematic science among them.

The enamel, encaustic, and fresco work of the ancients has come down to us in profusion. Their paintings on paper, canvas, leather, and wood have mostly perished. The even climate of Egypt and the seclusion of the tombs excavated in the rock by its ancient inhabitants have, however, preserved many specimens of their painting on wood and fabric in the mummy cases and wrappings.

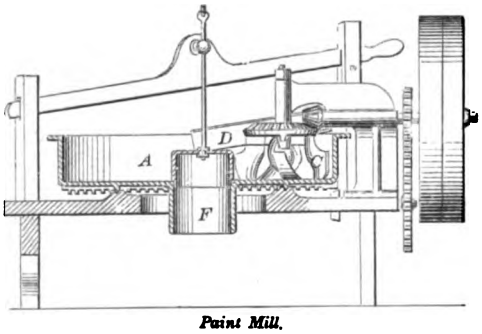
The bricks of Mesopotamia and the pottery of Etruria are also very ancient and interesting, the latter especially exhibiting a refined taste.

The modes in which colors may be applied to produce various effects, and possess more or less endurance, are described under DESTEMPER, ENCAUSTIC, ENAMEL, GLASS, OIL, SIZE, WATER-COLORS. See list under FINE ARTS.

Paint-mill. A machine for grinding pigments.

In Fig. 3493, a circular pan *A* containing the paint is rotated by appropriate mechanism, while stirring

Fig. 3493.



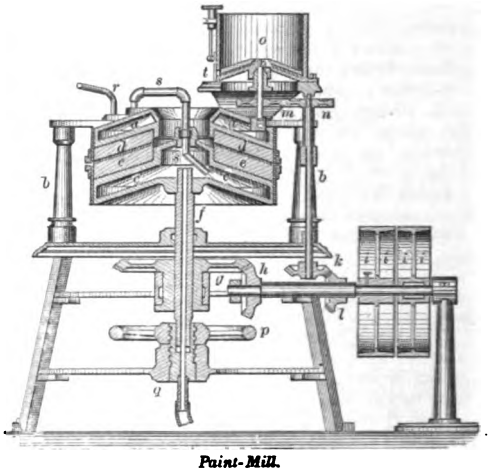
Paint Mill.

and scraping feet are caused to revolve therein by means of bevel-gearing. The discharge is effected by a curved scraper *C*, which brings the mass to a central opening *F*, provided with a tubular cover or valve *D*.

In Masury's paint-mill the upper millstone bed *a a* is supported on pillars *b b* bolted to a cast-iron table; both the upper and lower beds *a a c c* are hollow and receive thin annular disks of stone *d d e e*: the lower is supported on a hollow shaft *f* rotated by the bevel-gears *g h*, driven by the pulleys *i*, which also, through the medium of bevel-gears *k l* and spur-wheels *m n*, turn an arm in the mixer *o*.

The lower stone is raised into contact with the upper one by turning the wheel *p*, which raises the screw-step *q* of the hollow shaft *f*, which slides through the bevel-wheel *g*. The stones are cooled by water admitted through the pipe *r* to the open space *a a*, whence it passes through the pipes *s s'* to the open space *c c* in the lower bed, and is discharged through the tubular shaft *f*. The material to be ground is placed in the mixer *o* and gradually fed into the mill through a small opening *t* provided with a gate for regulating its flow; the lower stone is

Fig. 3494



Paint-Mill.

brought into the required proximity with the other in the way above described, and a continuous flow of water allowed to circulate through the hollow spaces within the beds; by this means the particles of paint may be ground to an extreme degree of fineness without material evolution of heat. Mills constructed on this principle may also be used for grinding other substances.

Pair-horse Har'ness. The general name given to double harness in England.

Paix'han Gun. A large chambered shell-gun, so called from Colonel Paixhan of the French army, who introduced it in 1822.

Guns of this kind of the caliber of 8 and 10 inches, known as sea-coast howitzers, formerly constituted a part of the armament of coast fortifications in the United States. These differed from the *columbiad*, invented by Colonel Bomford, United States army, about 1812, in being lighter in proportion to their caliber and in having no elevating rack on the cascabel, and have been superseded by ordnance of more modern forms. See CANNON.

Pa'la. (*Nautical.*) The blade of an oar. The *wash*.

Pal'ace-car. (*Railway Engineering.*) A car fitted with first-class accommodation, sofas and chairs, instead of the ordinary seats. The car is usually fitted for conversion into berths or couches for night traveling. See SLEEPING-CAR.

Pal'an-quin'. A carriage borne by men who relieve each other at intervals. It is an ordinary mode of conveyance in India and China.

Fig. 3495.

Palanquin.

Pal'ate, Ar'ti-fi'cial. A plate applied in cases of cleft palate, to improve articulation. It consists of an aluminium, gold, silver, or rubber plate, accurately fitted, to close up the opening in the roof of the mouth.

Digitized by Google

Pale. 1. A kind of fencing consisting of vertical slats supported by posts and rails, or posts and wires. *Paling.*

2. (*Shipbuilding.*) One of the interior shores for steadying the timbers of a ship while building.

Pal'ette. 1. (*Painting.*) A thin oval plate of porcelain or other material, having a hole near one edge through which the thumb may be inserted, used by painters in oil for rubbing-up or holding colors.

2. (*Metal-working.*) The breastplate against which the person leans to furnish a pressure for the hand-drill. Sometimes called a *conscience.*

3. (*Surgical.*) *a.* A light wooden spatula used for percussion, to excite the tone of the skin and tissues.

b. A splint to hold a burnt hand in shape and prevent deformation by the cicatrices.

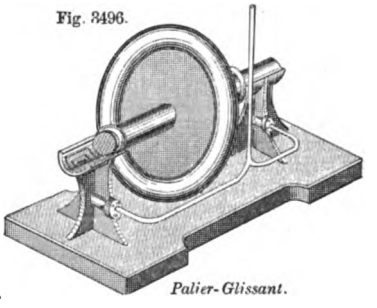
c. An instrument composed of two perforated plates to catch and withdraw the stylet in operations for *fistula lachrymalis.*

Pal'ette-knife. A flat, thin, flexible knife with a rounded end, used by painters to mix colors on a palette, or on the grinding slab. A *spatula.*

Pal'ier-glis'sant. A "slippery support" for a shaft or axle, a film of water being introduced beneath it by pressure. It is described for vertical and for horizontal shafts in Bramah's planing-machine, English patent, 1802. The inventor makes it adjustable by pumping in water *ad lib.* See HYDRAULIC PIVOT; WATER-BEARING.

In Girard's palier-glissant the water, under a considerable head of pressure, is introduced beneath the

Fig. 3496.



Palier-Glissant.

journal, lifting it slightly from its bearings; after two or three oscillations the journal assumes its proper bearing on the box, the water flowing between them in a continuous and almost infinitesimally thin sheet. The comparative friction of this and a bearing lubricated by oil may be tested by imparting rotation to two wheels journaled, one in each way, by hand, when that provided with the palier-glissant will be found to maintain its rotation much longer than the other; if, however, the supply of water be cut off, the wheel immediately stops.

Pal'imp-sest. A piece of parchment whose original writing has been removed in order to fit it for a subsequent record. Many old documents were thus obliterated, and the writing is restored by an infusion of gall, dilute hydrochloric acid, oil, etc., a certain trace of the materials of ink remaining in the substance of the parchment which acts upon the substance applied.

Pal-i-sade'. (*Fortification.*) A row of stakes set firmly in the ground and presenting a sharp point to an advancing party. The stakes are placed vertically at the foot of the slope of the counterscarp, or presented at an angle at the foot of a parapet, or on the banquette of the covered way.

Pal-i'ta. A light shovel. A trowel.

Pal-la'di-um. Equivalent, 53.3; symbol, *Pd.*; specific gravity, 11.8; difficult to fuse. Discovered by Dr. Wollaston in 1803.

It is a white, malleable, ductile, hard metal; fusible with the oxyhydrogen blowpipe.

The alloy of palladium and silver is eminently suitable for the graduated circles of mathematical instruments.

Palladium was used in constructing the balances for the United States Mint, and has been used for the medals of some learned societies.

Palladium alloyed with silver and copper makes an elastic, non-tarnishing blade capable of high polish.

Pal-la'di-um-iz'ing. A process for protecting iron by means of a thin coating of palladium, in lieu of zinc, as in the so-called "galvanizing" process.

The articles to be protected are first cleansed, as in zincking, by means of the double salts of zinc and ammonia, or of manganese and ammonia, and then thinly coated with palladium, applied in a state of amalgamation with mercury.

Pal'lam-poor'. A style of East Indian cotton chintz, printed in large-sized pieces and used for counterpanes. The printing is in the *resist* style, a substance being painted on the cloth having the power of *resisting* access of the dye to the fabric. With the *pallampoor* cloth this was softened wax laid on with a hair-pencil. We have no means of ascertaining how long this style of the art has been practiced, but it seems to be as old as Pliny. Madras has long been famous for this manufacture. One piece 5½ yards long by 2½ broad (French yards) is mentioned by Ure: "said to be the labour of Hindoo princesses, which it must have taken a lifetime to execute."

Pal'let 1. (*Machinery.*) A click or pawl to which a reciprocating motion is imparted, and by which an intermittent rotary motion is communicated to a wheel, as in many feed motions; or by which the rotary motion of a wheel is made intermittent.

2. (*Horology.*) In an escapement, a lip or leaf connected with the pendulum, or upon the arbor of the balance-wheel, as the case may be, and acting consecutively upon the teeth of a wheel which is driven by the main-spring or weight, and is known as the *scape*-wheel.

3. One of the series of disks or pistons in the chain-pump or chapelet.

4. A bed; a mattress; a palliasse.

5. (*Painting.*) An oval board or piece of ivory to hold paint. A *palette.*

6. (*Nautical.*) A ballast-locker in the hold of a small vessel.

7. (*Clay.*) *a.* A board on which a newly molded brick is carried away to the *hack.*

b. A potter's wheel.

c. A paddle used in beating and shaping plastic material in forming crucibles, etc.; or in taking up mortar for use.

8. (*Bookbinding.*) *a.* A tool for gilding the back over the bands.

b. The instrument with which gilders take up gold-leaf from the pillow.

Pal'let-mold'ing. (*Brick-making.*) As distinguished from *slop*-molding. The bricks are turned out of the mold on to a piece of board of somewhat larger area, called a *pallet,* and on this they are removed to the drying-ground. In pallet-molding the molds are usually sanded; in slop-molding they are wetted.

Pal-li-asse'. (Fr. *Paillasse.*) An under bed of straw. A straw mattress.

Digitized by Google

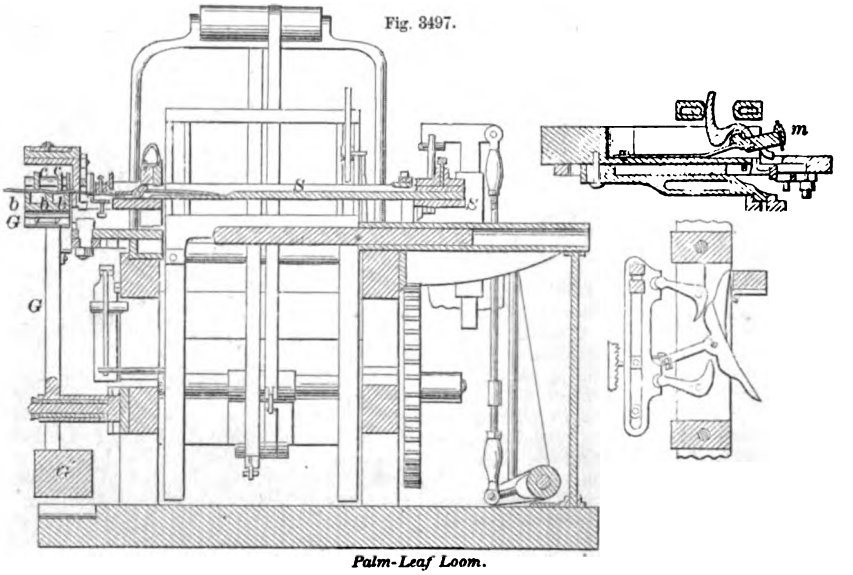
Palm. 1. (*Nautical.*) *a.* The sailmaker's substitute for a thimble. It goes over the hand, and has a fitted shield by which the needle is pushed through the canvas.

b. The flat face of an anchor-fluke which forms the holding surface. See ANCHOR.

2. The breadth of the hand, four inches.

Palm-leaf Loom. Strips of palm-leaf of proper width and length for the weft of the desired fabric are placed side by side between fingers *b c* at the top of a vibrating holder *G* at the side of the loom-frame. The ends of the strips next the selvedge are cut off evenly by a knife, and a weight *G'* at the bottom of the holder keeps the holder pressed in one direction

Fig. 3497.



Palm-Leaf Loom.

with sufficient force to keep the edge of the strip to be selected against a gage about in line with the selector. A feeding-arm *m* catches the end of one strip at a time and presents it to the selector *S*, which has at one end a pair of pinchers, and the selector draws the strip between the warps. The weaving mechanism is as usual.

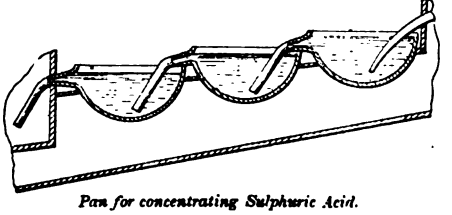
Palm-tree. (*Pyrotechnics.*) A device consisting of a series of green fires on a frame representing the body and head of a palm-tree. It was first designed by the Roman pyrotechnist Ruggieri: the composition is crystallized verdigris, 4; sulphate of copper, 2; sal-ammoniac, 1: ground with alcohol and used to saturate cotton rovings, which are festooned about the frame, and fired before the spirits have evaporated.

Pam'phlet. (*Printing.*) A work consisting of more than one sheet and not over five. It has a paper cover, if any.

Pan. A vessel for boiling or evaporating. Originally an open metallic vessel in which sirups or solutions are boiled for the purpose of concentration or crystallization, as a *sugar-pan*, *salt-pan*, etc. See EVAPORATING-PAN.

The purpose being maintained, closed vessels for the same purpose are also called *pans*. See VACUUM-PAN.

Fig. 3498.



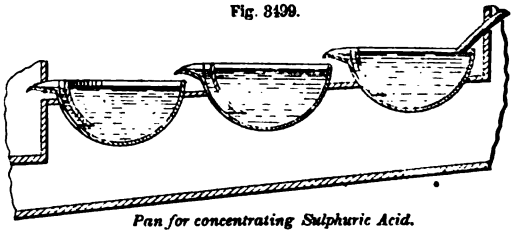
Pan for concentrating Sulphuric Acid.

The shape being preserved, open vessels in which the contents are not heated are called *pans*, as an *amalgamating-pan* (see AMALGAMATOR), *prospecting-pan* (see GOLD-MINING).

1. Overflow furnace-pans are used in concentrating sulphuric acid. In Fig. 3498, the upper pans discharge by pipes near the bottom of the next pan in the series. The effect is to move the whole contents of the pan below.

In Fig. 3499, each pan overflows into the one next below, and by means of the partial partition and spout the liquid is taken from the bottom of

Fig. 3499.



Pan for concentrating Sulphuric Acid.

the pan, where it is in the most concentrated condition.

2. (*Soap-making.*) Soap-pans are made with a wooden frame and an iron bottom; called, respectively, the *curb* and the *pan*.

The same device is used for the preliminary heating and partial condensation of the sugar-water or maple sap, as it is variously called in different sections of the United States.

3. (*Tin-plate Making.*) A cold pot with a grating at the bottom in which tinned iron-plate is put on edge to drain and cool. It is the fourth in the series of iron pots and pans used in the manufacture

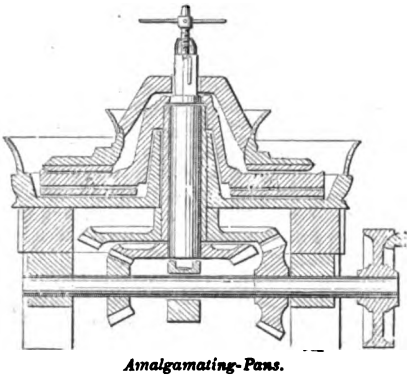
Digitized by Google

of tin-plate. *Tin-pot, wash-pot, grease-pot, pan, list-pot.* See TIN-PLATE.

4. (*Metallurgy.*) A name applied to that description of amalgamator consisting of an open metallic vessel in which the comminuted ore and quicksilver are ground together by rotating mullers. There are many varieties, which are described under the *Pan Process.* See AMALGAMATOR.

In the example, the pan has a central conical hub, through which a hollow shaft passes. On the lower part of a spindle which passes through a hollow shaft is keyed a bevel-wheel, and on the lower part of the said shaft is also keyed a similar bevel-wheel, and into these wheels beveled pinions gear, by means of which the mullers are rotated in opposite directions. On the upper part of the hollow shaft a square is formed, which is above the conical hub, and on this square is fitted the square portion of a conical hub, which extends down over the hub and is connected

Fig. 3500.



Amalgamating-Pans.

with the muller, which is provided on its under face with shoes. A sleeve provided with a slot is fitted over the upper end of the spindle, and a pin passes through said slot and spindle. This pin and openings cause the spindle to rotate the sleeve, while the openings allow the said sleeve to be adjusted by means of a screw.

5. The powder cavity of the old flint-lock fire-arm.

6. (*Carpentry.*) The socket or sole for a hinge.

Pan-a-ma' Hat. A leaf hat made in Ecuador and New Grenada of the undeveloped leaf of the "bombonáje" (*carludovica palmata*), which is a screw pine rather than a palm. The trunk of this plant is only a yard in hight, but the leaf-stalks are two yards in length. The bark of these leaf-stalks is woven into baskets, and the expanded leaves are used for thatching. It is the leaf before it has opened that is prepared for the manufacture of hats. It then consists of a bundle of plaits about two feet long and one inch in diameter. The green outside of this "cogollo" or bunch is stripped off; and then, by an instrument called a "picadera," resembling a pair of compasses with legs set half an inch or less apart, according to the fineness of the straw required, the leaflets are made into strips of uniform size with parallel sides. The cogollo is then boiled to toughen the fiber, and hung up in the sun to dry and whiten, when the leaflets run up into cordlike strands, which are then ready for use. The longest straw which can be procured from the bombonáje is twenty-seven and a half inches. It takes sixteen cogollos for an ordinary hat and twenty-four for the finest; and a single hat is plaited in from four days to as many months, according to texture. — PROFESSOR ORTON of Vassar.

Pan'cake. (*Leather.*) A factitious leather made of scraps agglutinated by cement or glue, and pressed into a flat cake for insoles, etc.

Pan-de'an Pipes. The emblems of Pan, the rural divinity of the Greeks, were a shepherd's crook and a pipe of seven reeds. Fig. 3501.

The reeds are bound together in a parallel series, the mouths on a level and the lengths so proportioned as to give the notes of the gamut.

Pandean Pipes.

The instrument yet survives in England as an accessory to the exercises of Punch, playing the air to a base-drum accompaniment. See SYRINX.

A porcelain representation of the Pandean pipes was found by Dr. Abbott at Sakkarah.

Pan-dore'. (*Music.*) A rebec. A kind of lute. See *Pandura*, Plate LI., Bonanni's "Istromenti Armonici," Roma, 1776.

Pane. 1. A compartment or square.

a. A sheet or light of window-glass occupying one opening in a sash. In the *apodyterium* of a Pompeian bath was a pane of cast glass 2 feet 8 inches by 3 feet 8 inches. In the *tepidarium* was another window with four panes.

b. One square of the pattern in a plaid or checker-work fabric.

c. One of the sides of a roof, tower, spire, etc.

2. *a.* A flat dressed side of a stone.

b. One of the parallelopipeds of buhr-stone which are confined by hoops and form a millstone.

3. (*Joinery.*) One of the divisions of a work which has sunken portions surrounded by framing. A PANEL (which see).

4. (*Machinery.*) The divisions or sides of a nut or bolt-head; as, a *six-paned* nut, *i. e.* a hexagonal nut. *Panel* is an allied word.

The pointed or edged end of a hammer-head. Properly PEEN (which see).

5. (*Hydraulic Engineering.*) One of the divisions of a plat between a feeder and an outlet drain.

6. (*Diamond-cutting.*) One of the sides of the *table* or upper surface of a *brilliant-cut* diamond. The table has eight panes. See BRILLIANT.

Pan'ei-con'o-graph. See PANICOGRAPH.

Pan'el. 1. The sunken portion of a *door*, wainscoting, head-board of a bedstead, etc. Its edges are mortised into the surrounding frame, whose uprights, in a door, are termed *stiles*, and horizontal pieces, *rails*. Middle vertical pieces between double panels are *munions*.

Carriage panels are, in the United States, usually of poplar strengthened by strong canvas fastened thereto by glue.

2. A compartment in a sunken ceiling, soffit, bay, or wainscot.

3. A face of a hewn stone.

4. (*Painting.*) A thin board on which a painting is made.

5. A square. See PANE.

6. (*Bookbinding.*) *a.* A depressed part of the sides within a relatively elevated bordering portion.

b. A space on the back between bands.

7. (*Mining.*) *a.* A heap of dressed ore ready for sale.

b. A system of coal-mining in which the projected *winning* is divided into large square allotments divided by massive walls of coal, instead of placing the whole working in one undivided arrangement. The *pillars* are left very large, the *rooms* small; the *pillars* are worked out, props being substituted; these are knocked out and the *goaf* filled up by the caving down of the ceiling.

8. A pad or packing beneath a saddle to protect

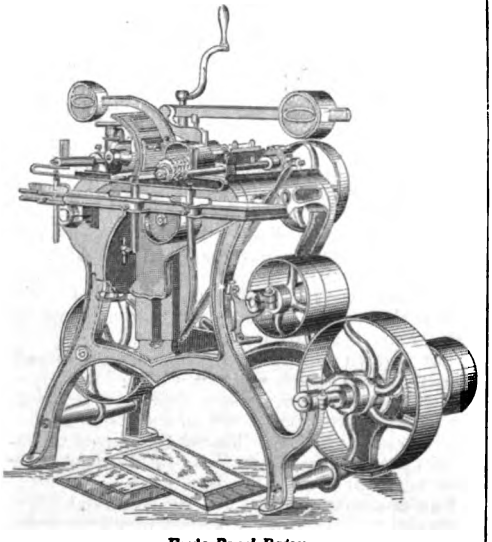
Digitized by Google

the horse's back from contact with the tree. It is usually made of basil stuffed with wool, doe-hair, or horse-hair, lined or quilted with woolen serge, or at times, for hot climates, with holland, and for race-saddles with silk or other soft material. The principal difficulty with panels is to keep them of their original softness.

Pan'el-plane. (*Wood-working.*) A long stocked plane having a handle or *toat*. The stock is somewhat deeper than that of the jack-plane.

Pan'el-rais'er. (*Wood-working.*) One employed to rabbet away the angle and a part of the surface of a board, in order to give it a sunken margin, leaving a *raised panel*. The cutters have such a contour as to give the required molding to the edge of the raised portion. The example is known as a *double-head panel-raiser*, working upon two edges of the board at once, at a gaged distance apart. A couple

Fig. 3502.



Fay's Panel-Raiser.

of the worked panels are shown on the floor below the machine.

Pan'el-saw. A hand-saw for paneling. It has six teeth to the inch.

Pan-ic'o-graph. A mode of obtaining printing-plates direct from a subject or transfer by applying it to the face of a plate of zinc, and building up a printing surface in relief corresponding to the design transferred. The processes are: —

1. Place on the polished plate the design in transfer ink; dust rosin on the ink, which gives it hardness and substance; then eat in the uncovered surface.

2. Coat the zinc with a non-conducting surface; draw or write the design with a conducting ink; throw down copper on the lines in the electroplating bath; remove the non-conducting coat and eat down the zinc surface by making the plate the positive electrode of the battery.

3. Coat the plate with whiting and etch with a point; cover with varnish, which will adhere to the uncovered metal; wash off the whiting and bite in the parts of the plate not covered by the varnish.

Panne. (*Fabric.*) Worsted plush of French manufacture.

Pan'nier. 1. (*Hydraulic Engineering.*) A basket or gabion of wicker-work containing gravel or earth, and used in forming a basis for earthy material in the construction of dikes or banks to exclude water or to resist its eroding action upon its natural banks.

2. Baskets — usually in pairs — slung over the back of an animal of burden to carry a load. The ancient Egyptian paintings show asses with panniers full of children.

Pan-nus-co'ri-um. A kind of leather cloth used for making boot uppers.

Pan-o-ra'ma. A painting of a complete scene, such as that of London as viewed from a central point, by Barker, from the summit of St. Paul's, or made continuous upon an unrolling canvas, as if the spectator were passing the particular spots consecutively.

In a *diorama* the scenes are isolated and viewed through a large opening, the surrounding proscenium affording a frame for the picture or succession of pictures. This mode of pictorial representation was invented by Daguerre and Bouton. It has great facilities for scenic and illuminative accessories, by opaque and transparent painting, screens, shutters, reflectors, etc.

A *cyclorama*, as its name indicates, is, or should be, a circular view.

The invention of the panorama is due to Barker, a portrait-painter of Edinburgh, who obtained a patent for his invention in 1787. His panorama of Edinburgh was painted in 1789. In 1792 he exhibited his panorama of London. Fulton introduced the art into France, 1799. In 1821, during the absence for repairs of the cross of St. Paul's, Barker erected an observatory at that giddy hight, and during the summer completed his sketches on 280 sheets of drawing-paper, covering 1,680 square feet. The painting made from his drawing adorned the interior of the dome of the Athenæum, Regent's Park, London.

The panorama of the Mississippi was made in 1840 by the skill and patience of the painter Banvard, who floated down the river and took the sketches of prominent points and expressive features of the river-banks. It gave rise to a host of similar productions: oceans and river routes, pilgrims' progresses, paradises lost, funerals of Napoleon, moral, immoral, and temperance serials, trades, arts, politics, overland routes to India, emigration to Australia and New Zealand, and, to cap the climax, a cyclorama of the great Lisbon earthquake, which happened about one hundred years previously.

Pan-o-ram'ic Cam'e-ra. (*Photography.*) One in which pictures may be taken on one flat plate, including an angle of 90°, more or less, as required, without introducing defects due to oblique pencils of light. Invented by Sutton. The lens-tube is turned about its axis and directed in succession to the different portions of the field, the dark slide moves with it and presents the proper portion of the sensitized plate opposite to the lens.

Pan'o-type. (*Photography.*) A name given to collodion pictures.

Pan'ste-re-o-ra'ma. A model of a town or country in wood, papier-maché, cork, etc., in which the objects are shown in the proportional relief.

Pan-tel'e-graph. An instrument invented by the Abbé Casseli, for transmitting autographic messages and portraits.

The essential features of the invention are a line connecting a pair of pendulums which have isochronous vibrations. The pendulum at one end of the line carries an iron point over the portrait or message executed or written in insulating ink on a metallic paper, and the other pendulum at the other end of the line carries an iron pencil over a paper

Digitized by Google

prepared with a solution of the yellow cyanide of potassium.

The electric circuit is completed where the stylus at the transmitting end crosses the insulating ink, and at a corresponding place on the paper at the delivery end a blue mark is made by the other stylus on the prepared paper. See AUTOGRAPHIC TELEGRAPH.

Bonelli's telegraph is of somewhat similar character. See Deschanel's "Natural Philosophy," Part III. pp. 730 - 733.

Pan'tile. A tile curved to an ogee shape, so that the prominent edge of one is covered by the dependent edge of the next. The usual size is $14\frac{1}{2} \times 10$ inches, and they are laid with a 10-inch gage. 170 tiles cover 1 square, i. e. $10 \times 10 = 100$ square feet.

Fig. 3503

Pantile.

Pan'to-chro-nom'e-ter. An instrument which is a combination of the compass, sun-dial, and universal sun-dial.

A sun-dial is attached to a magnetic needle, suspended in the usual way, in such a manner as to allow for the variation. The divisions of the hours and their fractions are carried on to an additional exterior circle, correspondingly divided; and to a fixed circle around the dial, on which are inscribed the names of a number of places. By this arrangement the gnomon gives the time at the place of observation and also for any other place inscribed upon it.

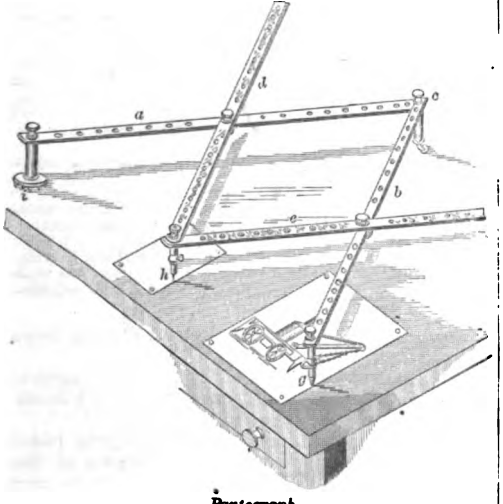
Pan'to-graph. An instrument for copying drawings. Its invention is ascribed to Christopher Scheiner, a Jesuit, 1603. It has since undergone various modifications and improvements.

A device of this kind is alluded to by Pepys.

"This evening Mr. Spong [the inventor] came and first told me of the instrument called a *parallelogram* [pantograph], which I must have one of, showing me his practice thereon, by a map of England." — PEPYS'S *Diary*, October 27, 1668.

The pantograph consists of four metallic rules, two of which *a b* are jointed at *c*, and the other two

Fig. 3504.



Pantograph.

d e are jointed over *h*; each rule is perforated with a series of holes, and the two *d c* are provided with thumb-screws by which they may be connected to *a b*, at either of the holes of the series. *g* is a tracer; *h*, a pencil or pricker; and *i* a screw or point which is forced into the drawing board or table to hold the instrument in position.

For use, the rules *d e* are secured to the others by inserting the thumb-screws through the holes marked with the numbers; as, $\frac{3}{4}$, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, etc., corresponding with the scale to which the drawing is to be reduced or enlarged; the point *i* is fixed in a convenient position, and the tracer *g* passed over the outlines of the original; this causes the point *h* to move in a direction parallel to that of the tracer, the extent of its motion being governed by the adjustment above described; and if a pencil-point be employed it describes a figure similar to the original but differing from it in size. In right-line drawings it is more usual to employ a plain needle-point, pricking a sufficient number of points into the paper to serve as a guide to the draftsman, who afterward connects them by lines. The instrument shown in Fig. 3504 is the one used in the reduction of drawings for the illustrations in this work.

The pantograph is used in transferring patterns to copper cylinders for calico-printing. The system was patented by Rigby in England in 1854, and improved in 1857, so that by employing a number of tracers all the similar figures in a pattern may be produced at once.

In this process the pattern to be copied is first drawn on paper which is placed in a camera which throws an enlarged image on a sheet of paper; this is traced on the paper, which is then transferred to a zinc plate, in which the figures are cut with a graver. The plate is then laid on the curved bed of the pantograph machine, on which a varnished roller is mounted; a number of diamond-points corresponding to that of the lateral repetitions in the pattern are brought in contact therewith, and the tracer is successively passed over each part of the enlarged pattern on the zinc plate, causing the diamond-points to describe a series of figures, reduced to the size of the original drawing on the varnished copper cylinder, which are afterward etched in with acid.

The *micropantograph*, for copying on a very minute scale, may be described as a system of connected pantographic levers, the last of which carries a piece of glass on which the original is reduced in a proportion determined by the relation between the lengths of the longer and shorter arms of the series.

The glass rests and moves upon a diamond-point while the point remains stationary. The diamond may be raised or lowered by appropriate mechanism, to regulate the width and depth of the cut or entirely remove it from the glass.

With an instrument of this kind the Lord's Prayer has been written within the space of $\frac{1}{3600000}$ of a square inch. In the same ratio the whole of the Old and New Testament would be contained within $\frac{1}{27}$ of a square inch. See MICROPANTOGRAPH.

Pan-tom'e-ter. An instrument for measuring angles for the determination of elevations, distances, etc.

Pa'per. A material made in thin sheets from a pulp of ground rags or other fiber, and used for writing or printing upon or for wrapping. The name is derived from *papyrus*, an Egyptian reed whose stalk furnished for so many centuries the principal material for writing upon and for wrapping, to the nations bordering upon the Mediterranean. In his day, Pliny remarked: —

"All the usages of civilized life depend in a remarkable degree upon the employment of paper. At all events, the remembrance of past events."

This observation, undoubtedly true 1,800 years ago, is much more remarkably so now; indeed, in considering that paper as we now understand it was

Digitized by Google

entirely unknown to Europe in the time of Pliny, the expression of the great dependence upon what seems to us so fragile and inefficient a substitute for real paper appears strange.

The Greek name *papuros*, mentioned by Theophrastus, a contemporary of Aristotle and Alexander, was probably the Egyptian name of the reed with a Greek termination. It was also called *biblos* by Homer and Herodotus, whence our term *bible*. The term *volumen*, a scroll, indicates the early form of a book of bark, papyrus, skin, or parchment, as the term *liber* (Latin, a book, or the inner bark of a tree) does the use of the bark itself. Hence also our words *library*, *librarian*, etc.

Pliny indorses the statement of Varro that the discovery of the use of the papyrus was an incident in the victorious expedition of Alexander of Macedon; this was not correct, but no doubt the expedition contributed to introduce the papyrus to the nations of the West. Egyptian tombs show that it was used many ages before the time of Alexander, and, indeed, long prior to any authentic historical accounts of Greece; its existence being proven nearly as far back as the stone records of Egypt extend, or nearly to the time of Menes himself (2400 B. C.).

It seems to have been early known to the Hebrews. Isaiah refers to the papyrus plant when he says, —

"The paper reeds by the brooks, and everything sown by the brooks, shall wither, be driven away, and be no more."

This prediction of the prophet has been long since fulfilled, and the plant is now comparatively rare.

An ancient Egyptian papyrus on the preparation of medicines, which was found at Thebes by Dr. Ebers, has lately been placed in the Leipsic Library. It is in a good state of preservation, and consists of one hundred and ten columns; written on the back is a double calendar in eight columns. Each column is eight inches wide, and contains twenty-two lines. The writing is from right to left; it is all in black ink, except the beginnings of chapters, which are in red ink. The characters are distinct, bold, and tasteful, and their form appears to fix the seventeenth century B. C. as the date of the manuscript; the fact that in the calendar the name of King Ra-ser-ka (Amenophis I.) is mentioned, proves that the papyrus is not posterior to the first half of that century.

The work itself dates from a period more remote than its transcription on papyrus. It is known that the most ancient Egyptian writings were works about medicine. Manetho tells us that the Egyptians honored one of their first kings as a physician. This assertion is confirmed, not only by the fragment of papyrus of Brugsh and Chabas, preserved in the Berlin Museum, but also by the present document.

The first chapter of the papyrus treats of the original production of the book, which came from the Temple of On (Heliopolis). Then follow the remedies employed for the cure of various diseases, together with extensive details as to diseases of the eye, remedies against the falling off of the hair, for sores, fevers, the itch, etc. The chapter devoted to the mistress of the house is succeeded by one about the house itself, which insists on the importance of cleanliness, and tells how to banish insects, to exclude them from houses, to prevent serpents from coming out of their holes, to avoid the stings of gnats and the bites of fleas, and to disinfect clothing and dwellings. Then there is a treatise on the relations between soul and body, with secret methods of studying the heart and its movement.

The gossiping and agreeable Pliny gives a detailed account of the preparation of paper from the Nile reed. This indefatigable man is principally known to us by one only of his voluminous writings, his treatise on "Natural History." This, however, treats on a great multitude of subjects, including agriculture and the arts and sciences, and affords a very interesting record of the state of practical knowledge at that time. He was suffocated by the mephitic vapors at the eruption of Vesuvius, A. D. 79, which he had imprudently approached too nearly, for the purpose of scientific investigation.

It may be remarked, that this eruption of Vesuvius, described with so much animation by Pliny the Younger, did not utterly destroy the cities of Herculaneum and Pompeii as is popularly supposed. We find them emerging from their ruins in the reign of the Emperor Titus, in the fifth year of whose reign they suffered so much. They yet subsisted in the reign of Hadrian, under the Antonines, and are mentioned as inhabited cities in the chart of Peutinger, which is of the date of Constantine. The eruption of A. D. 471 was probably the most frightful on record; and if we may believe Marcellinus, the ashes of the volcano were vomited over a great portion of Europe, reaching to Constantinople, where a festival was instituted in commemoration of the strange phenomenon. After this, we hear no more of the cities, but the portion of the inhabitants who escaped built or occupied suburbs at Nola in Campania and at Naples. In the latter city, the *Regio Herculanensium*, or *Quarter of the Herculaneans*, an inscription marked on several lapidary monuments, indicates the part devoted to the population driven from the doomed city.

From Pliny we learn that the papyrus plant grew in the marshes of Egypt or in the sluggish waters of the river Nile in pools which did not exceed 3½ feet in depth, forming a gracefully tapering stalk, triangular in cross-section and not over 16 feet (10 cubits) in hight.

The paper made from papyrus was of nine different qualities, varying in size, color, and texture. It was made "by splitting the successive folds of the stalk with a needle into very thin leaves, due care being taken that they should be as broad as possible. That of the first quality is taken from the center of the plant, and so on in regular succession, according to the order of division."

Each quality was known by a different name, as "Augusta," "Liviana," "Hieratica," etc., the latter from the fact that it was reserved for religious books. The "tamotic" and "emporatica" were sold by weight, and used by dealers for wrapping, while the bark was used for making cordage.

All these various kinds were made upon a table moistened with Nile water; a liquid which, when in a muddy state, was supposed to have some of the properties of glue. There is little doubt, however, that this adhesive property was inherent in the plant itself, and in some instances we know that paste was employed. The table being first inclined, the flakes of papyrus were laid upon it lengthwise to such length as the papyrus would admit of, the jagged edges being cut off at either end; after which a cross-layer was placed over it. When this was done, the leaves were pressed close together and then dried in the sun, after which they were united to one another, the best sheets being always taken first, and the inferior added afterward. There were never more than twenty of these sheets to a roll. The width varied according to quality from thirteen to six fingers' breadth.

In making, the leaves were beaten and thinned out with a mallet, and the leaves united by paste. Roughness was subsequently smoothed down with a burnishing tooth or shell, which polished the surface. We may remark that modern microscopical investigation has demonstrated the fact that three instead of two layers of the liber were usually if not universally employed.

As a material for writing upon, the Mexicans used cotton cloth or skins nicely prepared, or a composition of silk and gum, but principally a fabric prepared from the aloe, *Agave americana*, called by the natives *metgey*, which grows freely over the table-land of Mexico. The paper somewhat resembles the Egyptian *papyrus*, and is polished to resemble parchment. It took color and ink excellently, and many specimens remain. It was sometimes rolled up in scrolls; at other times was made up in packs of leaves, with a tablet of wood for the outsides. The leaves were separate.

A species of incombustible paper was made from asbestus in the time of Pliny.

To give an idea of the bulky nature of papyrus manuscripts it may be mentioned that Ovid's Metamorphoses occupied fifteen rolls.

The abundance of papyrus in Egypt, the chief source of its production, the magnificence of the kings of that country, and the concourse of learned men who resorted thither, caused it to become the seat of those immense libraries which we read of as having perished in the flames during the siege of Alexandria by Julius Cæsar, B. C. 47, under Theodosius about A. D. 388, and finally under Omar the Saracen about A. D. 639. During this interval, however, the Alexandrian library had been increased

by the addition of that of Eumenes, king of Pergamos, which had been presented by Marc Antony to Cleopatra. The volumes composing this latter were written largely on parchment, and, according to the old story, this material was invented or discovered by Eumenes, about 200 B. C., in consequence of a prohibition laid on the exportation of papyrus from Egypt, due to the fact that one of the Ptolemies wished to have no rivals in the matter of libraries, and proposed by this means to prevent Eumenes from proceeding with his proposed collection. The latter, however, it appears, was not to be thus deterred from his favorite project, and contrived a method of preparing skins of animals which fully answered his intended purpose.

As skins for records had been known for so many ages, among the Hebrews for instance, we may fairly presume that the invention of Eumenes merely related to a peculiar mode of dressing. It may be conjectured, perhaps, that previous to the time of this king writing upon skins had been done with paint, and not with ink. Paint consists of a pigment ground in oil, and ink is a dye dissolved in water. The former does not flow freely, and cannot well be used with a pen, but requires an implement of the brush kind for its proper application. Neither, however, can well be applied to skins which still retain a large portion of their fatty matters; an ink can hardly be used at all for forming legible characters on skins in this condition, though a paint, to a certain extent, may.

Parchment, in addition to having been selected and reduced to a regular thickness, has been specially treated with detergents, and a proper surface raised by pumice-stone, so that it is adapted to receive and retain ink. Papyrus being the ordinary material for writing, and being eminently calculated to receive the aqueous colored solution called ink, it was the object of Eumenes to render the skins of animals suitable for the reception of such a fluid, and avoid the necessity of going back to the use of paints. The name of Crates of Mallos is honorably associated with that of Eumenes in the enterprise, if not the invention.

All public documents under Charlemagne were written on parchment except by the Popes, who used papyrus till the twelfth century. Papyrus continued to be used for epistolary correspondence till the introduction of paper by the Saracens.

The bull of Pope Agapetus, dated 951, was written on papyrus, and perished in the burning by the French communists of the library of the Louvre, May 24–25, 1871.

Many ages must have passed in Egypt before the ingenious mode of obtaining paper from papyrus was devised. At this distant period we may assume that Pliny's remarks were true of the Nile land, as in that writer's own age they were true of Asia and parts of Europe.

"At first men wrote upon leaves and afterward upon the bark or rind of trees." Reference has already been made to the terms *volumen* and *liber*, and the origin of another set of words is no less apparent. The modern word *page* is from the Latin word *paginæ*, flat leaves; and the word *leaves* is also applied, being the translated form of *paginæ*, as *page* is the derived word. *Folio* is also from *folium* (Latin), a leaf, indicating the material so commonly used. Writing on palm-leaves was practiced among all peoples where that tree flourished; the Singhalese and other East-Indian nations retain it to the present day. Oblong pieces of the green leaf are trimmed uniformly, so as to be strung together to form a book, — a shaky and insecure binding, but one quite common in museums. The writing is scratched through the external cellular matter of the leaf, which shrinks away from the incision, into which a black pigment is sometimes rubbed.

Many other materials have been used by savage and semi-civilized nations for records more or less enduring. Under the article PEN may be found some references to pictured and inscribed rocks, to writings on tablets, skins, stones, slabs of clay, bones, shells, linen, metallic plates, and ivory. See PEN.

Close at home we have an excellent substitute in an emergency, birch-bark, used by the northern tribes of Indians. In Polynesia and Oceanica, as well as in China and Japan, the *Morus papyrifera*, or paper-mulberry, yields an inner bark which is of great value. In Java and Sumatra it is the ordinary material for writing upon. Its use as a garment is perhaps most extensive among the Feejees.

Among these ingenious cannibals the *tappa* cloth, as it is termed, is made by removing the bark from the tree in strips six feet long and three inches wide. These are soaked and then beaten on a table with flat grooved mallets, until the strip is extended into a sheet as wide as it is long. This is then flattened with a smooth mallet, and pieces may be united by beating their edges together.

In the due course of the ages, papyrus and parchment having rendered an elastic pen (*calamus*, a reed) and a fluid ink the most convenient materials for writing, we find they long maintained an almost uninterrupted sway, the variations being in the use of waxed tablets, leaden plates, and waxed linen, as explained under PEN.

The great change occurred when *true paper* was made of *rags or other vegetable fiber, reduced to a pulp, gathered into a sheet, felted in setting, and dried.*

Human invention had, in this case, been anticipated by the wasp, which insect may be considered as a professional paper-maker, devoting a large portion of her time and energies to the production of this fabric, of which she builds her nest. For this purpose she seeks dry wood,—fence-rails and weather-beaten boards are a favorite source of supply,— which she saws or rasps by mastication, mixes with a natural size exuded for the purpose, works into a paste, and spreads into sheets in a manner truly marvelous Any one who has pelted hornets' nests with stones from a safe distance, or given them a passing blow with a stick as they hang from a limb in the orchard, will be led to admire the strength which a pulp of chewed wood and albumen may be capable of exhibiting

The structure is generally a prolonged irregular spheroid, wonderfully light, and is bound by repeated layers and bands of paper to the bough from which it is suspended. The material resists rain, partly from the shape, the roof being rounded; partly from the fact that the successive layers overlap, or, in other words, that the dome is *shingled;* and partly, we presume, from its being rendered semi-waterproof by the size in its composition

The mode of procedure is interesting. Having finished the ceiling, the hornet begins to build the first terrace of her city. The females and neuters do most of the work among all insects of this class. The charges and distractions of maternity are, however, in most cases removed from the workers whose gender is suppressed, though the mother hornet, unlike the queen bee, is eminently industrious. To resume: the upper terrace of cells in the interior of the structure is of a general circular shape, and is suspended from the ceiling of the dome by a stalk and stays of the same material which composes the body of the nest. The cells in the terrace are hexagonal in form, and have their mouths downward. These are not appropriated to honey, as the insects do not lay up provisions, but they are devoted to the rearing of the young. A set of cells being completed and eggs laid therein, the work is intermitted, and the mother's time devoted to supplying food for the grubs, which soon require her care. When, in a few weeks, they are able to go abroad themselves, they help extend the quarters, and a new terrace is constructed, supported by stems from that above. The community of paper-makers may amount to 30,000 in a single season, according to Reaumur.

The Chinese, at the time of Kung-fu-tze (about 600 B. C.), wrote with a style upon the liber of trees, as their records state. Paper was used, perhaps invented, in that country in the reign of Wan-te, 179–

Digitized by Google

156 B. C. That made previous to the Christian era is supposed to have been of silk. Engrossing on cloth and silken stuffs had been practiced for many centuries previously. The Chinese silk paper is stated by Martini to have been invented in China about 120 B. C., and to have found its way into Persia and Arabia about A. D. 620.

The bark-paper of China is made in the following manner: The small branches of a species of tree resembling the mulberry (*Broussonesia*) are boiled in lye to loosen the bark; this is then macerated in water for several days, the outer part scraped off, and the inner part boiled and agitated in lye until it separates into fibers. It is then washed in a pan or sieve and worked by the hands into a pulp, which is afterward spread on a table and beaten fine with a mallet. The pulp is next placed in a tub containing an infusion of rice and a root called *oreni*, and thoroughly stirred to mix the materials. The sheets are formed by dipping a mold, made of strips of bulrushes confined in a frame, into the vat containing the pulp, and are, after molding, laid one on another with strips of reed between. A board and weights are laid on the pile to express the water, and they are then separated and dried in the sun. This paper is so delicate as to bear writing on one side only. When it is desired to write on two sides a couple of sheets are pasted together back to back.

The Chinese paper of bamboo fiber is likewise very ancient, and is made by pulping and gathering the pulp in films.

The Chinese *rice-paper*, so called, is prepared from the inner portion of the stems of a hardy leguminous plant that grows plentifully about the lakes near Calcutta and also in the island of Formosa, whence the Chinese import it in large quantities. The stems of the plant being cut into the proper lengths for the sheets, the pith is cut spirally into a thin slice, then flattened, pressed, and dried. It thus resembles very closely the papyrus in the mode of manufacture.

It is said that in Japan, previous to the year A. D. 280, silken stuff, with a facing of linen, was used for writing upon. Subsequently paper was imported from the Corea, and about 610 A. D. the *Broussonesia papyrifera* (paper mulberry) was introduced, from which the greater part of the paper now used in that country is made.

This is manufactured by boiling the stalks of the plant, causing the bark to separate. The outer portion of this is converted into paper of an inferior quality, while the inner skin is treated by farther boiling, washed, and pounded by beating with clubs on a wooden table. The pulp thus formed is made into balls, from which portions are broken off as required and mixed with a paste made from the root of the *troro*, a sort of shrub. The mixture, thoroughly incorporated and of proper consistency, is poured into a mold consisting of an inner and outer frame, the former having a false bottom. The sheet thus formed is turned out of the mold and dried on boards. The whole process and its manipulations bear a striking analogy to those employed in making hand-laid paper in the European way, as will be subsequently described. The process differs in some respects from the Chinese plan described above.

The conquests of the Saracens cut off the supply of papyrus to Europe, and that energetic people made amends by introducing true paper.

They are supposed, by their conquests in Bucharia about the year 704, to have acquired the art of making cotton paper, and substituted it for the silk of the far East and the papyrus of the South. In the eighth century the Saracens conquered Spain, and through that peninsula the art of making paper reached the rest of Europe. In the same century, the art is said to have been introduced into Constantinople from the East. Paper was made by the Saracens in Spain from flax, and afterward from cotton. Some time previous to this, however, a cotton paper, made in Damascus and designated as *Charta damascena*, had been known in Europe.

An Arabian author of the thirteenth century states that cotton paper was invented at Mecca by one Joseph Amru, about the year of the Hegira 88, that is, A. D. 706. Another Arabian authority states that a paper manufactory was found at Samarcand, in Bucharia, when the Arabs conquered that country in the year of the Hegira 85.

The oldest manuscript written on cotton paper in England is in the Bodleian collection of the British Museum, and bears date 1049. The most ancient manuscript on the same material in the Library of Paris is dated 1050. In 1085 A. D., the Christian successors of the Spanish Saracens made paper of rags instead of raw cotton, which is recognized by its yellowness and brittleness. A very early specimen of *linen* paper is found in a manuscript bearing the date of 1100 A. D.; though some twelve years afterward we find Roger, king of Sicily, granting a charter to some paper-makers who were then established on that island. The paper made by them was, however, probably of cotton, which was then extensively grown in Sicily.

In 1151, we learn from an Arabian author that paper of a superior quality was manufactured at Xativa, in Spain, the Christian Spaniards having improved upon the processes of the Moors, from whom they learned the art, by stamping the raw material, raw cotton and rags, by the aid of a water-mill.

In 1170, Eustathius, the commentator on Homer, remarks that papyrus had fallen into disuse.

In 1178, we find several specimens of flax paper in Spain, and in the University of Riteln in Germany a document is preserved, signed by Adolphus, Count of Schaumberg, made from linen rags. A letter from Joinville to Louis X. of France, dated 1315, and written on paper made from rags, is yet extant. After this period the notices of paper and of paper-making become frequent.

Linen paper is found in documents of 1241 (edict of Emperor Fred. II.) and 1300. The Arabian physician Abdollatiph, who visited Egypt in 1200, says that the mummy-cloths (*linea*) were habitually used to make wrapping-paper for the shop-keepers. The linen paper of the thirteenth century had the water-lines and water-mark. One specimen had a tower.

The earliest manuscript on linen paper known to be English bears date fourteenth year of Edward III., 1320. The first water-mark, a ram's head, is found in a book of accounts belonging to an official of Bordeaux, which was then subject to England, dated 1330. It has been claimed that linen paper was made in England as early as 1330, though it is supposed that no linen paper was made in Italy previous to 1367.

In 1390, Ulman Strother established a paper-mill at Nuremberg in Bavaria, operated by two rollers, which set in motion eighteen stampers. This indicates the process of pulping the fiber by beating, which continued in use for nearly four centuries. This was the first paper-mill known to have been established in Germany, and is said to have been the first in Europe for manufacturing paper from linen rags.

In 1498, an entry appears among the privy expenses of Henry VII. for "a reward given to the paper-mill," 16 *s.* 8 *d.* This is probably the paper-mill mentioned by Wynkin de Worde, the father of English typography. It was located at Hartford, and the water-mark he employed was a star within a double circle. The jug or pot was a favorite water-mark about the middle of the fifteenth century, preceding the fool's cap, which has given its name to the largest size of writing-paper now in common use. About 1540, it appears that Henry VIII. of England, to show his animosity to the Pope, with whom he had then quarreled, used for his private correspondence a

Digitized by Google

paper of which the water-mark was a hog with a miter.

The barbarous law of England imposing a duty on paper appears to have had a precedent in France under Charles IX., the author of the St. Bartholomew massacre, who, in 1565, levied an impost on that article, which was soon abolished at the instigation of the University of Paris.

It appears that wall-paper, as a substitute for tapestry or hangings, began to come into vogue about the year 1640.

It does not appear that the paper manufacture flourished in England until after the revolution of 1688, as we find that in 1663 England imported from Holland alone paper to the amount of £ 100,000.

This hardly preceded the establishment of paper manufactories in America, as we find that William Rittinghüysen, anglicized Rittenhouse, — a name afterward memorable in the history of American science, — a native of Holland, in conjunction with old William Bradford, one of the earliest of American printers, who will be doubtless remembered by those who have read Franklin's Autobiography, established a paper-mill at Roxborough, near Philadelphia, on a stream still called Paper-mill Run, a tributary of the Wissahickon. The raw material for its supply was derived from linen rags, the produce of the old clothes of the vicinity, and native rags long continued to be the chief source from which American paper was derived. In 1710 another paper-mill — the second in America — was erected at Crefeld, now forming part of Germantown, by William De Wees, a connection of the Rittenhouse family. In 1724, William Bradford endeavored to induce the New York legislative council to grant him a monopoly for the exclusive manufacture of paper for fifteen years, but was unsuccessful.

Reaumur in 1719 suggested, from the examination of wasps' nests, that a paper might be manufactured from wood, but we do not find this idea farther acted upon until a later period, when inventors seem to have exhausted their ingenuity, regardless of expense, in the selection of materials from which paper might be manufactured.

Paper, in fact, cannot, as a general thing, be economically made from fibrous material which has not already previously been manufactured. That is to say, so long as the prices of vegetable fibrous substances, as cotton, flax, etc., remain the same, it will be much more economical to use them for the purpose of reducing into pulp for paper-making after they have already undergone the process of manufacture into clothing, than to take them in their raw state, when they may still be subservient to the economic physical wants of man.

Since Reaumur first suggested wood as a substance from which paper could be made, the articles proposed for that purpose have been almost innumerable; in fact, anything having a fibrous texture *may* be used, and the question resolves itself into one of economy. See PULP-BOILER.

Koops in 1800 published a work on paper, which was printed on paper made of straw, with an appendix on paper made of wood. A second edition was published in 1801, upon paper re-made from old printed and written paper. In 1835, Piette published a work on the subject of "Paper from Straw," etc., giving 160 specimens.

In 1765, Schaeffer, of Ratisbon, printed a book on sixty varieties of paper made from as many different materials; a copy is now in the Smithsonian Institute Library.

In 1786, the Marquis de Vilette published in London a small book, printed on paper made from marshmallow; at the end are leaves of paper manufactured at Bruges from twenty different plants, such as nettles, hops, reeds, etc.

The following is a list of materials (numbering in all 402) from which paper has been made or proposed to be made, with references to the authorities from which the information has been derived.

PAPER-MAKING MATERIALS.

The following materials, among others, have been used or suggested for paper-making. The authorities are cited as follows: —

a refers to English patents.
b refers to Examiner's Digest, Patent Office.
c refers to Munsell on Paper-making.
d refers to Schaeffer on Paper.
e refers to "Central Blatt," "Papierfabrikation," Dresden.
f refers to "Journal des Fabricants de Papier," Paris.
g refers to "Die Fabrication des Papieres," Piette, Cöln.

In the modern process of paper-making, the rags, linen or cotton as the case may be, are sorted by hand into various qualities, proper for different kinds of paper, the best and finest of course being selected for the stock from which the better qualities of writing-paper are to be made.

The sorting is done by women and children, who work at tables covered with wire-net. Each table has a stationary knife at its edge, against which the rags are drawn so as to divide them into shreds, the dust and dirt falling through the meshes into a receptacle below. The sorted rags are next washed

Digitized by Google

with hot water and alkali, usually in a circular pan similar to the *bucking keir* employed in bleaching, and are afterward reduced to pulp by the rag-engine. It was formerly customary to allow them to ferment or rot by steeping them for several weeks in vats; but this practice, occasioning great loss and sometimes injuring the rags by discoloration, has caused the process to be superseded by the treatment of boiling in alkaline lye, by which a large saving is effected. The fermentation, however, materially assists in the process of disintegration, rendering the pulping comparatively easy. Pulping was formerly effected by beating in mortars of hard wood having an iron bottom provided with teeth, the pestles or hammers being grooved so as to cut the rags to pieces. The hammers were either so arranged as to rise and fall perpendicularly, like the stamps of an ore-crusher, or else were so disposed as to operate in the manner of a trip-hammer. The mortars were finally superseded by the rag-engine, which was invented in Holland about the middle of the seventeenth century, and which still maintains its place in the manufacture. Of these two are employed, sometimes arranged one above the other so that the stuff when partially pulped in the upper one may be let down into the lower. The two are alike in general construction, consisting of an oblong trough with semicircular ends. They are made of wood lined with lead, or may be entirely formed of cast-iron. The trough is divided by a longitudinal partition, on one side of which is journaled a revolving cylinder provided with teeth. This cylinder is capable of being raised or lowered, and works against a block fixed in the lower part of the trough, which is also provided with cutters corresponding to those of the cylinder.

The first or upper machine is termed the *washer*, as into it the rags, after being boiled in lye, as previously described, are introduced. A current of water is allowed to flow through the trough, and the roller, in its elevated position, is set in motion, which thoroughly washes and cleanses the rags. The roller is then lowered in its bearings and the speed of rotation increased, causing a constant current circularly around the trough, carrying the pulp between the roller and the block until it is reduced to what is technically known as *half-stuff*, which is then transferred to the second engine, known as the *beater*. During this part of the process the bleaching material is added. The beater or pulping-engine is precisely similar to the washer, but its roller and block are provided with a larger number of cutters, and it is driven at a higher speed. Size, and smalt for imparting a blue color to the paper, were formerly added at this stage of the process, but the latter practice has now fallen into disuse. It is a pity that the same cannot be said with regard to barytes and other substances employed to impart whiteness and factitious weight to the paper, so as to make a very inferior article appear good to the unpracticed eye.

The pulp in its finished condition is called *whole stuff*, and is run into a reservoir, whence it is taken out as wanted to supply the vats.

Formerly, all paper was made by hand, and it is believed that a better article can be produced in this way than machine made. However this may be, machine-made paper has carried the day, and is now, perhaps, the only kind made in this country, though in England and the Continent of Europe *hand-laid* writing-paper is still manufactured.

The process is as follows: The pulp, after having been sufficiently comminuted in the beater, is transferred to the vat whence it is to be molded into sheets of paper. The *mold* is a shallow rectangular frame, having a top composed of close parallel longitudinal wires, which are crossed at more distant intervals by transverse wires of larger size. The marks of these wires are very evident in examining old specimens of paper. The water-mark is also inwoven into the mold, so as to leave its impress in the pulp in a way which cannot afterwards be eradicated. To the mold is applied an open rectangular frame, called the *deckle*, the interior dimensions of which exactly correspond with those of the intended sheet of paper. It is held closely against the mold by the hands, and the two together are dipped into the vat containing the pulp and withdrawn horizontally, leaving a layer of pulp on the mold, to which a horizontal vibration is given while the water is draining off, in order to insure a uniform distribution of the pulp and consequent uniformity in the thickness of the paper. When sufficiently drained, the deckle is removed from the mold, and the sheet of paper, now partially solidified, is transferred to a sheet of felt and covered with another sheet of the same material, on which another sheet of felt is laid, and so on alternately until a pile, usually of six quires, has accumulated, when the whole is transferred to a press, in which they are kept until an equal amount has again accumulated, when the first are removed, the alternating sheets of felt withdrawn, and the paper itself without the intermediate felts is again subjected to pressure. It is then hung up to dry on racks overhead, two or three sheets deep, sized by dipping in a solution made from the clippings of leather and parchment, again dried and pressed, examined and sorted. The blueing previously referred to constituted a part of the sizing process. Smalt was formerly employed for this purpose, but was finally, to a great extent, superseded by ultramarine, which latter, however, had the disagreeable result of allowing the gelatine size to decompose, thus imparting a most offensive smell to the paper, as may be well recollected by those of our readers who may have been brought in contact with the blue writing-papers at one time so much in vogue.

In 1798, Robert announced that he had discovered a means of making by machinery paper of large size, even 12 feet wide and 50 feet long; and in the succeeding year the invention was carried into practical effect at the paper-mill of François Didot, at Essone, France, in whose employment Robert was at the time. The invention was patented in this year. In 1800, a reward of 8,000 francs was granted by the French government to Robert, and permission was granted him to carry his working model to England, where, in fact, the invention was first brought into practical working form.

Gamble, in 1801, obtained a patent for a machine similar to that of Robert, but the credit of introducing the machine into England is due to the Fourdriniers and Donkin, the former of whom furnished the capital and the latter the skill. Donkin completed his first machine, acting on the ideas of Robert, in 1803; and in the succeeding year, Henry and Sealy Fourdrinier purchased the patents of Didot and Gamble. These gentlemen may be considered as the great introducers of machine-made paper, and, like many other projectors, were rewarded by impoverishment.

The Fourdrinier machine (1) receives the pulp on an endless web of wire-cloth, which passes over rollers. The Dickenson machine (2) employs a perforated cylinder, which serves as a substitute for this endless web. See Plate XXXVII., PAPER-MAKING MACHINE, where several kinds of paper and cardboard machines are represented.

Digitized by Google

Two hundred and ninety-nine Fourdrinier machines were running in the United States in 1872.

In 1809, Mr. Dickenson, an English paper-maker, invented the cylinder machine, in which a polished hollow brass cylinder, perforated with holes and covered with wire-cloth, is substituted for the endless wire-web of the Fourdrinier machine. In this the air is exhausted through the trunnions or axis of the machine. (See Plate XXXVII.) In the year 1872, 689 cylinder machines were running in the United States.

The patents on the subject of paper-making are very numerous. Donkin, however, who devoted so much time and talent to the matter, undoubtedly is entitled to the first rank after Robert, who suggested the idea of making paper in a continuous web.

One great difficulty to be obviated was the wetness of the sheet of pulp, which, of course, impaired its tenacity, rendering the manipulations exceedingly difficult. This was, in a large degree, removed by the invention of the *dandy* by Wilkes, patented in England in 1830. This is a hollow perforated roller, corresponding to the *doffer* of a carding-machine, over which the paper is caused to pass and is pressed under another roller. The dandy may be so constructed as to exhaust the air from beneath the paper by forming it of an inner and exterior casing of sheet-metal, but in practice this has not been found necessary.

The introduction of threads, net, or other woven material into the paper is described in Dickenson's English patent, 1809.

In the machine-made papers the trouble of assorting, trimming, and hanging up to dry is entirely avoided, a perfectly uniform thickness is attained, the time required to produce a sheet from the pulp is reduced from weeks to minutes, and sheets of indefinite length may be produced; for example, a sheet was made at Colinton, England, in 1839, on the Fourdrinier machine, over a mile long, 50 inches wide, and weighing 533 pounds. This length might perhaps be extended indefinitely.

Dickenson, who has been already mentioned as the inventor of the cylinder paper-machine, invented a paper composed of two webs of different texture, which were united while in a pliant condition, so as to render them inseparable; the web constituting the face was made of finer material than that intended for the back. This paper was particularly designed for copperplate printing. To prevent counterfeiting special papers have been devised, such as that used by the Bank of England and by the United States Treasury Department. In these cases the difficulty of manufacturing a similar article is relied on to prevent fraud; complicated and expensive machinery, not within the reach of ordinary counterfeiters, being required. The paper on which United States currency is printed contains silk fiber mixed with the pulp, producing a peculiar appearance, which is readily recognized, and which would be difficult, if not impossible, to imitate without the aid of the peculiar machinery by which the paper is produced.

A paper has also been made with a knitted fabric inclosed, which leaves an unerasable mark on the back of the fabric, and prevents all erasures and alterations of writing on its surface.

Analine (*an*, priv., without *line*, i. e. flax) is a name applied to paper destitute of flax, and must not be confounded with *aniline*.

Sponge paper is made by adding finely divided sponge to ordinary paper pulp. The paper absorbs moisture readily and retains it for a long time. It has been used to advantage for dressing wounds, and is capable of several important technical applications.

Incombustible paper and cloth were made of asbestus in the time of Pliny. The pulp is prepared in the usual manner from a pulp consisting of vegetable fiber, asbestus, alum, and borax, in about the following proportions: Vegetable fiber, one part; asbestus, two parts; borax, one tenth part; and alum, two tenths of a part. The vegetable fibers are minutely divided, and treated in the manner usual in the production of ordinary paper; the asbestus is also divided as much as possible, and the two are then intimately mixed with the alum and borax in a sufficient quantity of water to make a pulp of the requisite consistency, which is then made into paper by any of the well-known processes.

The fire-proof ink for writing or printing on incombustible paper is made according to the following recipe: Graphite, finely ground, 22 drams; copal or other resinous gum, 12 grains; sulphate of iron, 2 drams; tincture of nutgalls, 2 drams; and sulphate of indigo, 8 drams. These substances are thoroughly mixed and boiled in water, and the ink thus obtained is said to be both fire-proof and insoluble in water. When any other color but black is desired, the graphite is replaced by an earthy mineral pigment of the desired color. Paper is rendered transparent by a varnish composed of Canada balsam dissolved in turpentine.

Carbolic-acid paper is now much used for packing fresh meats for the purpose of preserving them against spoiling. The paper is prepared by melting five parts of stearine at a gentle heat, and then stirring in thoroughly two parts of carbolic acid, after which five parts of melted paraffine are added. The whole is to be well stirred together till it cools, after which it is melted and applied with a brush to the paper, in quires, in the same way as in preparing the waxed paper so much used in Europe for wrapping various articles.

Copperplate papers are made the same size as drawing-papers down to *medium*. Below this they are cut by the printer. The paper is more absorbent than *drawing*-paper.

This absorbent paper is without size, and is known as *soft plate*.

When engravings are to be colored, they are printed on sized drawing-paper, which is known as *hard plate* when used in this connection.

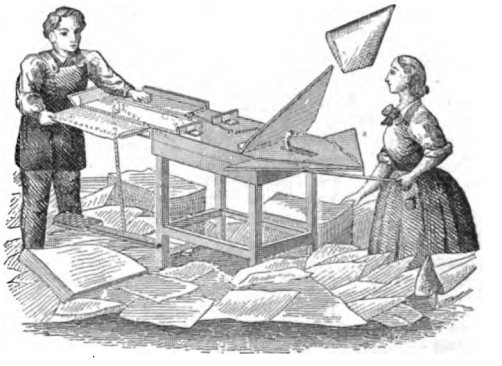
Pa'per-bag Ma-chine'. A machine, usually automatic, operating upon paper from the roll or upon blanks previously cut, to fold and paste it into bag shape.

The kinds are various, and the prominent ones will be cited in order of date. The principal and most successful ones take the paper from the roll, either of a width for forming a bag, or else cut into strips which are simultaneously acted upon by separate sets of devices. The strip, assuming there to be but one, is bent over into tubular shape, cut off into lengths, the shape at the point of severance being such as to leave a flap to paste over, and thus close the bottom ; or a piece is cut off the flat strip and portions of it are folded over the remainder and flaps pasted for closing the side and bottom ; or a piece is folded into a conical form with pasted flap. Other minor variations might be cited. Much of the ingenuity has been expended in cutting the paper to make no waste ; also in forms for so folding the portions at the bottom as to make what is called a satchel-bottom, where the parts are folded upon each other, making several thicknesses at the part most exposed to wear and tear.

Fig. 3505 is a hand-machine, having two ends at which square and conical bags are made respectively. In such case, a piece of paper of the required size and shape is laid upon the table and held by a hinged piece which corresponds to the inner size and form of the bag ; this former, holding down the sheet, side flaps are folded over, carrying with them portions of the paper

Fig 3505.



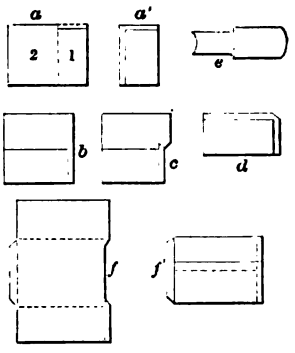
Paper-Bag Machine.

which lap upon each other a sufficient width for a pasting surface. One machine is shown operated by a hand-lever, the other by a treadle. The farther one, for square bags, has a bottom flap for the bottom piece, which folds over upon and is pasted to the side pieces.

Wolle, October 26, 1852, and May 29, 1855, was perhaps the first to make bags by automatic machinery. The bag made is shown at *a a'*, Fig. 3506. *a* is the blank with a notch ; the portion 1 is folded over the part 2, and then appears as represented at *a'*. The folding over of the top and bottom flaps fin-

Digitized by Google

Fig. 3506.



Blanks for Paper Bags.

ishes the operation. The paper is fed from a roll, the web is cut into oblong sections, notched, folded by a blade which drives the bottom edge between rollers, from whence the folded blank passes to the gummers and flap-folders.

b c d shows a bag in successive stages as made in Wolle's machine of July 6, 1858. The piece is not removed to form the notch, but is folded in to make double the bottom of the bag.

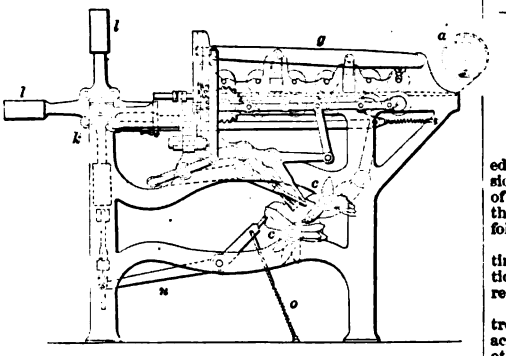
The Rice machine, April 28, 1857, was the first to bend a continuous web of paper over into a tubular shape and cut it off obliquely, so that an angular piece is left to be bent over and form the flap of the bag-bottom.

e represents a blank cut from a continuous web in a Goodale machine, May 29, 1855. The narrower portion is folded on to the wider, and the side flaps pasted and turned down. The bag has a projecting lip, due to the curved line of severance.

f f' shows Goodale's paper bag, July 12, 1859. This cuts from the web without waste, and the bottom has two flaps, strengthening it at that point. See also his patent, Aug. 28, 1859.

Koch's paper-bag machine, March 13, 1855, is adapted for making bags or boxes, the paper from a continuous web *a* being drawn between successive sets of rollers, etc., which are caused to turn intermittingly in one direction by means of cams on a shaft operating jointed levers and connecting rods. As the paper moves onward it is cut to the proper form and size by a cutter or cutters vertically reciprocated by the lever *g*, which,

Fig. 3507.



Koch's Paper-Bag Machine.

together with a corresponding lever on the other side, derives its motion through an intermediate series of levers from cams on the shafts *c c*. The lever *g* also operates the paster.

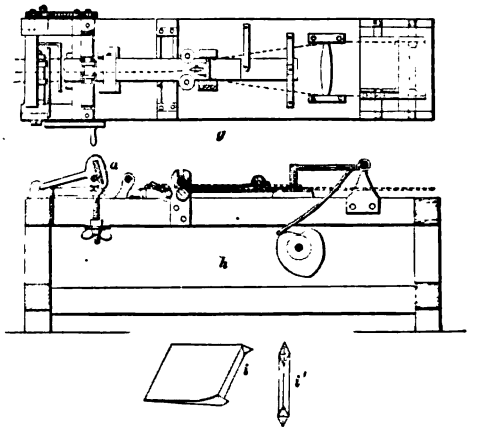
After being pasted the blank is carried forward by the two succeeding pairs of rollers and received upon a slide which forms one side of a hollow mold within which the bag is formed; at the same time the shaft *k* is rotated one quarter around, so that one of the formers *l* is in proper position to permit slides corresponding to the three other sides and the bottom of the bag to be successively brought up against it; this is effected by cams on the shafts *c c*, which operate compound levers connected with the slides and having toes against which the cams strike during the rotation of the shaft.

The forward movement of each slide turns in its side of the paper upon the former *l* and joins the pasted edges. The bottom is also similarly turned in and united to the sides. Farther rotation of the shafts *c c* causes the withdrawal of the slides and imparts a movement to the *former*, on which is the completed bag. This is withdrawn from the *former* by a pair of nippers or pinchers, which are caused to rise at the proper moment and seize the bag, by the bent lever *n* actuated by a spring *o*. The nippers is withdrawn, taking with it the bag, by a semicircular cam on the shaft *c*, its jaws being opened and closed at the right time by projections on the standards between which it works.

Pettee's machine, May 29, 1860. The roll of paper is fed beneath an elevated roller, and, passing over and partially around a drum, passes beneath the folder, which consists of two longitudinal strips with an opening between them, through which one edge of the paper projects, enabling paste to be applied by means of a horizontally revolving paste-wheel. Passing onward, it is seized by two clamps, drawn over a slide, and the two sides united so as to form a tube. As it is released by these clamps, it is seized by a second pair, which pass over the first, drawing it forward by a hand-over-hand movement, and passing it between the two blades of a stationary clamp, which holds it while it is severed by a reciprocating knife. It is then subjected to the action of a wedge-shaped trough containing paste. The lower edge of this trough has a longitudinal slit, the width of which may be adjusted so as to deposit the proper quantity of paste on the bottom of the cut-off bag. At the moment of depositing the paste the edge of the trough forces this part between two rollers, which bend over the edge of the bottom and complete the bag. The various motions requisite to the operation of the machine are derived from a driving-shaft, having belt and pulley connection with the motor.

g, Fig. 3508, represents the Armstrong machine, October 2, 1860. The bag is made from a continuous web, bent by a spindle-shaped roller and by side guides into a tube, the lapping

Fig. 3508.



Paper-Bag Machines.

edge pasted, the tube flattened, and then a bag cut off. The sides of the bag are held apart at different parts of the length of the tube, so that a single stroke makes an oblique cut across the tube of paper. The projecting serrated flap is pasted and folded over upon the body of the bag.

Greenough's machine, February 8, 1863, works from a continuous web, making square-bottomed, box-shaped bags, portions being removed from each side of the strip to make the requisite indentations and flaps.

Pettee, May 5, 1863, bends a continuous web of paper into a trough shape, by a pair of rollers adjustable in relative distance according to size of bag. Then the edges are bent over by another roller to form a tube, the edges gummed, a portion cut off obliquely to make a bottom flap.

Taggart, August 15, 1865, has a table with a slit which holds the flatly folded bag, exposing that portion above the table which is to be folded satchelwise.

k is the Goodale machine, September 12, 1865. The continuous web is cut by the descending knife *a*, giving the edge of the blank a wavy shape. The sides are then folded over by side flaps, the folded portions lapping over each other the width of the pasted surface. The bottom flap is turned over and pasted on to the sides.

i i' are two views of the Hollingsworth bag, January 24, 1865, which is made upon a vertical former with dilatable sides.

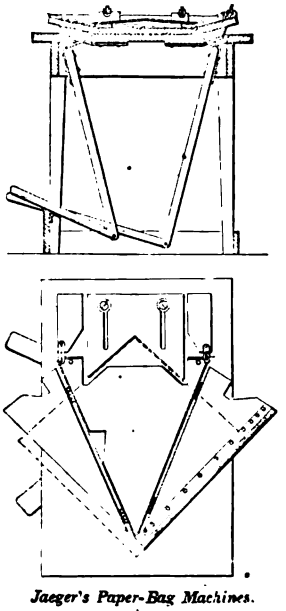
Jaeger's machine, May 7, 1857, is shown in Fig. 3509. It is somewhat similar to the one shown at Fig. 3508. It takes a square blank and folds over two angular flaps, making a conical bag.

Mallary's machine, July 28, 1868, like the Goodale machine just cited, has side and end flaps which fold those portions over the former. As the continuous sheet of paper is fed to the machine, the several devices perform their respective functions of delivering the paper to a knife, which cuts off a piece of suitable length for a bag, drawing such piece into the folders which produce the side laps, pressing the end lap against the pasting-roller, and at the same time turning it upward over the edge of the folding-blade, and then moving the bag forward between pressure-rollers, which join the pasted edges of the laps to the bag.

In his patent of November 3, 1868, one edge of the sheet is

Digitized by Google

Fig. 3509.



Jaeger's Paper-Bag Machines.

pasted by means of a roller as it passes into the machine; then one of its sides is folded over a former, and over it is folded the pasted side. The bag so far formed is drawn off by rollers, by which it is passed into an inclosure made with a bottom of a series of rollers, which carry it forward. One roller applies paste across the bag near the bottom, while another forms a fold for the bottom lap. It then passes out between another pair of rollers, which dress the bottom fold of the bag into place.

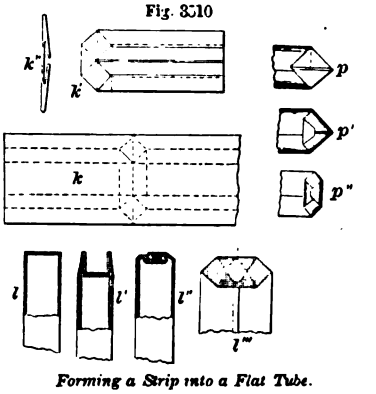
In Amazeen's machine, November 17, 1868, the paper, in passing into the machine from a mounted roll, has paste applied to its margin at one side, and is fed forward to toothed knives, which cut off a piece large enough to form a bag. The pasted and detached piece is then made to pass on beneath a plate or former, around which it is deflected into tubular form by bent guide-plates. The paper, being delivered from this forming device, has its pasted side pressed down upon the adjoining edge. One side of the paper tube is now longer than the other (a result due to the shape of the knives), and the mechanism, which finally comes into play, applies paste to the projecting end, folds it over to finish the bag, and discharges the latter from the machine.

Lockwood's machine, March 9, 1869. The web of paper is drawn over rollers *a d*, paste being applied to one edge by a roller in the trough *f*. It is partially formed in a tubular shape by the pivoted ball *g*, which prepares it for the action of the former *h*, by which, and the side clamps *i i*, the two edges are thrown over toward each other, but are prevented from touching by a finger until arriving at or near the guides and press-rollers which unite the two edges.

The tube is passed onward by a roll and endless band, which hold it firmly while being severed between the stationary serrated knife and a movable knife below it. The endless belt *n* conveys the bag into a position to be acted on by a knife, which is brought alternately into contact with a roller revolving in a paste-trough and with the end of the bag, which it pastes and creases preparatory to being seized by the rollers which, by pressing the turned-over portion and the body of the bag, form the bottom and complete the operation.

M. E. Knight's machine, July 11, 1871, manufactures flat or satchel-bottomed bags from a continuous tube of paper fed from a roll over a former, and cut, folded, and pasted. The peculiar feature is a device to hold back a point or portion of one edge of the paper tube, while the blade or tucking-knife makes the first fold. The successive conditions of the fold are shown at *p p' p''*, Fig. 3510.

Fig. 3510

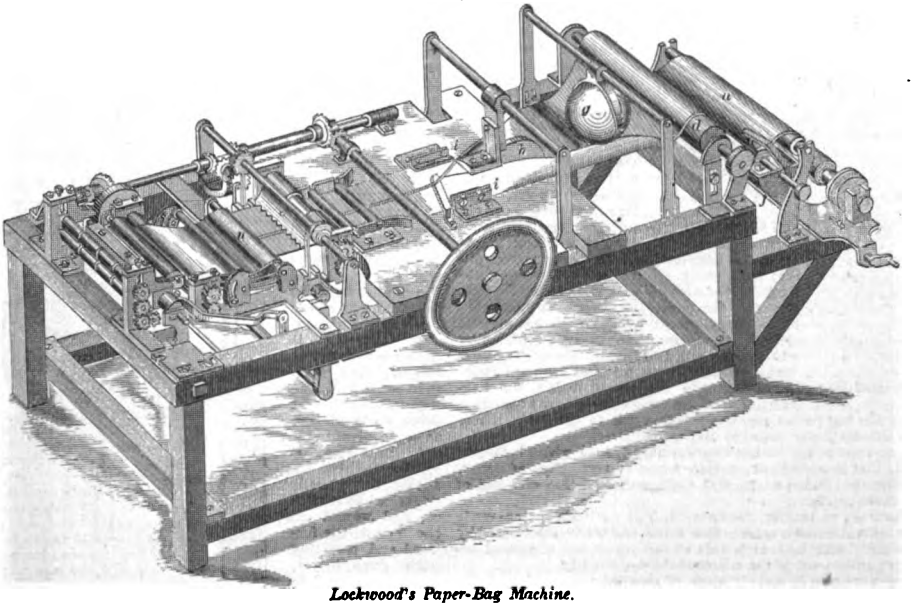


Forming a Strip into a Flat Tube.

In Arkell's machine, December 26, 1871, square-bottomed bags are made from a roll of paper, which is passed over a former, and its edges pasted together so as to be delivered in the form of a tube, which is cut into lengths, one end of which is cut, folded, and creased to facilitate the operation of forming the bottom. The partially formed sack is carried automatically through the machine on a carrier, which moves continuously in one direction, and on which it is subjected successively to the mechanism for applying the paste and finishing the bag bottom. Fig. 3510 shows the successive shapes assumed by the paper in forming a strip into a flat tube.

The Benner bag, January 9, 1872, is shown at *k k' k''*. A strip double the length of the bag to be formed is folded at mid-length. By the action of long formers, having at their sides hinged blades, the edges of the blank are folded, reverse folded,

Fig. 3511.



Lockwood's Paper-Bag Machine.

Digitized by Google

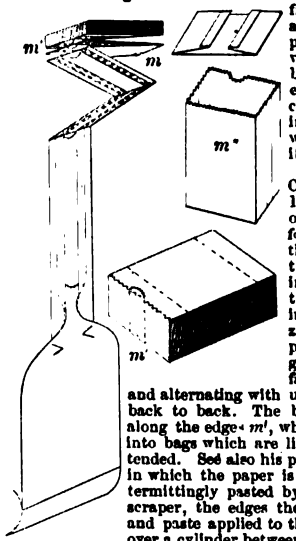
and lapped to form a tube which, when distended, is rectangular in section. See also Guild's patent, January 23, 1872

Bibby and Baron's English machine, October 1, 1872, for making square-bottomed bags, takes the paper tube from a roll, cuts, pastes, folds, presses, prints, and delivers the completed bag.

Annan's machine, November 12, 1872. A strip of paper, one edge pasted, is fed over curved guides (carrying diagonal spreading-rolls) attached to pivoted lever-arms, and its sides turned inward and lapped by twisted guides. This tube is pressed and fed forward by rolls (between which it is cut) upon a folding-table, where its lower ply is held down and the freshly pasted seam protected by an exhaust through orifices in the bed, and the forward end of the upper ply blown up by a blast through a pipe. Three rollers, journaled in cross-heads which reciprocate in radial slots of the revolving frame, successively carry the upper ply back on the tube to form the first diamond-end fold, the tube having been clamped by fingers at the angle thus formed; then deposit two lines of paste over the laps clamped by double fingers at the points where they are next to be folded, and after a folding-plate has folded over the last flap then lap the last fold on the opposite end of the bottom, the finished bag being fed out by rolls or belts.

In Hotchkiss's machine, January 28, 1873, the bag shown at l l' l'' l''' is made. The paper is fed by rolls from under the delivery-table over the recess of the folding-table, where it is held on one side by a spring and on the other by a gravitating bar, when a bag-length is cut by the shears. A right angular bar, rocked in and out of a vat, applies paste to one edge and part of the rear end. The rectangular former, descending, carries the blank into the forming-box, causing its sides to stand vertically, that which is dragged from under the bar being longest to form the overlap or seam. The folding-plate moves forward to lay one lap, followed by the opposite combined plate and roller, which lays the other flap and completes a square tube. These folding devices are so connected by levers, that one shall move in advance of the other, and the last folder plays under the pasting-table. The side-end folders are reciprocated successively to lay the side folds of the bag end, the pasted one first, over which partially completed end a paste-roll, vibrated out of a paste-vat, lays a line of paste on the inside surfaces of the top and bottom end-folds, the latter being protected by a supporting lip. The side-folders retreating, the upper end-folder descends and lays its fold, and, retreating, is followed by the lower end-folder, which completes the bottom. The *former* now rises, and, as a new feed is accomplished, its interior piston ejects the bag from the former on to a table, from which it is fed by an apron against the upper of a pair of rolls, where a vibrating bar breaks down its upper edge and forces the lower corner of the bottom into the bite of said rolls, which press and deliver it flat.

Fig. 3512.



Crowell Bag.

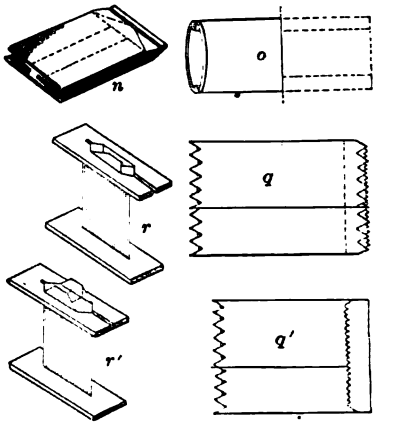
Fig. 3512 shows the Crowell bag, April 8, 1873, in which the edges of a strip of paper are folded in and then a portion lapped outwardly, the face of the latter being pasted. By doubling the strip thus prepared inward and outward, zig-zag fashion, as at m, the parts become united together in pairs, faces fastening paste to paste, and alternating with unpasted portions lying back to back. The bolt thus made is cut along the edges m', which separates the pile into bags which are like m'' when fully distended. See also his patent, October 14, 1873, in which the paper is cut longitudinally, intermittingly pasted by the paste-wheels and scraper, the edges then being folded under and paste applied to them. Thence it passes over a cylinder between it and a second cylinder, when the bottom is folded, the bag-length cut off, and the edges pressed together. Then the bag passes over the printing-roll to the table, where it is automatically removed and counted.

n represents the Parker bag, January 6, 1874, which is formed by folding inwardly the opposite edges of two strips of paper, uniting the folded edges, and folding and pasting one end of the united strips.

Crowell's paper-bag, January 13, 1874. *o* has a bottom made by a central transverse fold of the paper, and has its sides closed by edge-folds which, at each side of the paper, are cemented together and to one of the adjacent sides of the bag.

q q' illustrate Murphy's mode of making the division of the paper tube so that when the side portions, which are deeply serrated, are folded over upon the mid portion, both will be exposed to the pasting-brush, as shown at q, and may be securely fastened down to the side of the bag over which the bottom flap is folded.

Fig. 3513.

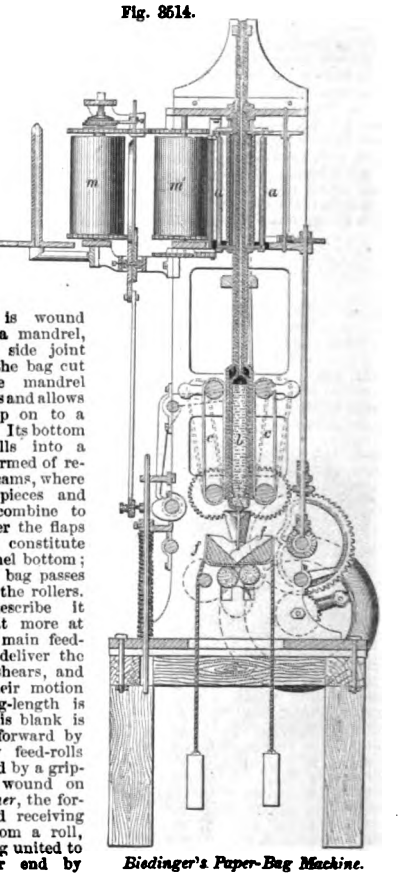


Paper Bags.

r r' illustrate the mode of making the Taggart bag, the blank being slipped into a slit plate, and then the portion projecting above the plate being folded down, first the ends and then the sides.

Biedinger's, March 10, 1874, is an upright machine in which the web of paper is fed upon its edge between a pair of vertical

Fig. 3514.



Biedinger's Paper-Bag Machine.

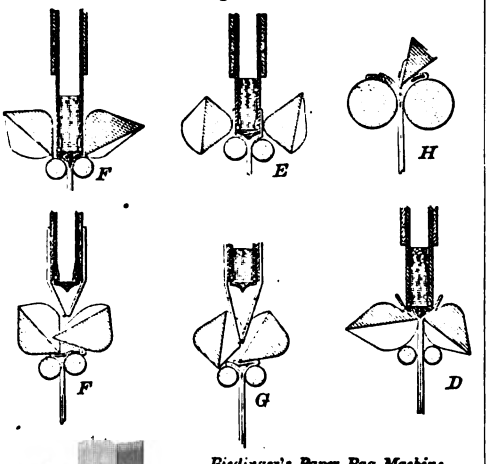
rollers, is wound around a mandrel, and, its side joint pasted, the bag cut off, the mandrel contracts and allows it to slip on to a former. Its bottom then falls into a cradle formed of revolving cams, where folding pieces and fingers combine to bend over the flaps which constitute the satchel bottom; and the bag passes between the rollers.

To describe it somewhat more at length: main feed-rolls m deliver the web to shears, and cease their motion as a bag-length is cut. This blank is carried forward by auxiliary feed-rolls m', seized by a gripper, and wound on the *former*, the forward end receiving paste from a roll, and being united to the rear end by

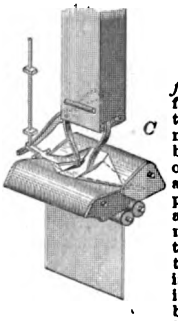
Digitized by Google

pressure against the delivery-roll. The *former* consists of a set of rolls *a a* on eccentric shafts, partially rotated, to expand the

Fig. 3515.



Biedinger's Paper-Bag Machine (Series of Operations).



former while making the tube, and farther rotated to contract it to release the tube, which falls on to a supplemental former *b*, over which it is fed by endless belts *c c* being made to pass over spring-arms and extended flat, and into the discharge-rolls, which propel it until a proper length projects above the bottom-folders. Folders *f f* now move inwardly, pressing against the retiring spring-arms, and form the triangular end-folds (Fig. *C*); retracting, they are followed by the descending piston, which rests on this partial bottom (Fig. *D*). The continuously revolving folders crease the sides against the angles of the piston, press a line of paste thereon, carry the piston and bag downward together until the central rib of the piston enters and spreads the bag-bottom in the bite of the discharge-rolls (Fig. *E*), where, the piston rising, the folders lay the side-laps successively (Figs. *F*, *G*), one folder (Fig. *H*) carrying a knife, folding the bottom centrally and into the rollers which discharge it pressed flat for packing.

Pa'per Boat. Paper boats or "shells" have of late years largely supplanted those of wood for racing and sporting purposes. These are made by applying sheets of manilla paper, or paper prepared from pure unbleached linen stock, to the exterior of a model or former corresponding to the interior lines of the shell. The sheets are fully equal in length to the model; and if manilla be employed, the first sheet is damped, applied smoothly to the surface of the model, and secured by tacking to strips on its upper face; it is then coated with an adhesive varnish, another sheet is applied over the first, and so on successively until the required thickness is attained.

When linen paper is used, but a single thickness of $\frac{1}{10}$ to $\frac{3}{8}$ of an inch is employed. The model with its envelope is then removed to a drying-room and exposed to a heat of 150° Fah., which obliterates all wrinkles in the paper and hardens it; it is next covered with boiled linseed-oil and turpentine, and afterward with shellac varnish; the framing is then inserted, and the decking and metal work put in place. Such boats may be made about one third lighter than wooden boats of the same dimensions, are impervious to water, and the skin is not liable to spring. See BOAT; CANOE.

Pa'per Box. Paper boxes are made in several ways.

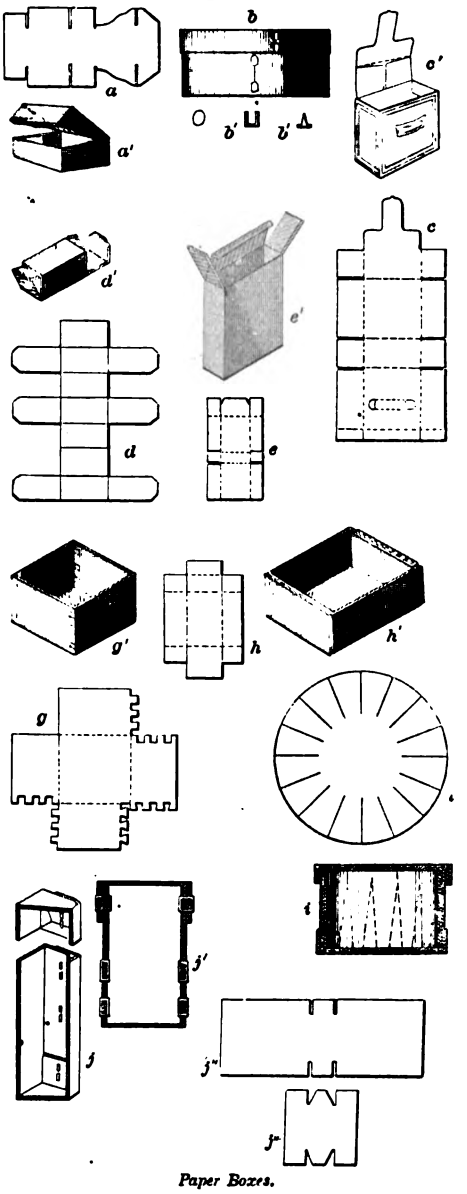
1. *Pill-boxes.* Paper from a coil is wrapped around a former, making a cylinder of a thickness depending upon that of the paper and the number of plies. The inside surface of the paper is coated with paste, and thus the joint is made. Such boxes are completed by pushing a disk of paper into the cylinder. The lid is but a shallow box, a trifle larger. Such boxes are also made by coiling a wide sheet of paper on a mandrel in the manner described, and then cutting it into lengths as desired. Lids are made in the same way. Colored boxes are made by an outer ply

Digitized by Google

of colored paper. Such boxes are also made by machinery. (See Fig. 3516.) In one mode of covering, the strip which is to cover the cylindrical portion has gored margins, which lap over upon the bottom of the box or the top of the lid, as the case may be, and match together.

2. Boxes are made from a roll of paper, which is bent over into shape, cut off, the bottom folded in

Fig. 3516.



Paper Boxes.

against a former, the contacting portions being pasted *in transitu*.

3. Boxes of paper or pasteboard cut from the roll, shaped, and secured by rivets or staples.

4. Boxes made from blanks of the required size and shape, the machine taking them from the pile, shaping and fastening the parts together. See PAPER-BOX MACHINE.

a a' are, respectively, a blank and a box made therefrom, the scale of the latter being enlarged somewhat. With the exception of two slight gores on the edges of the lid-flap, no portion is wasted. Some portions of the box are double and others treble. Parts secured by paste or rivets.

b b' b' show a round box and the metallic fastenings which hold the lapped portions.

c c' are the plan of the pattern and the folded box with a tuck and keeper. *d d'* illustrate another mode of shaping and folding. *e e'* still another, with a lapping lid. *g g'*, a paper box with dovetailing angles. *h h'*, the plan of a blank and the box made from a similar larger blank.

i, a box made from a circular blank, cut on the principle of *i'*, but of larger size.

j j' j'' j''', Heyl's box, whose overlapping pasteboard flaps are secured by rivets.

Seamless paper boxes, lamp-shades, hats, and other hollow articles of paper are made upon formers which are dipped into the pulp; the latter collects on the reticulated surface by means of a partial exhaustion of the air from the interior of the former, the air being withdrawn through an elastic pipe communicating with a bellows or cylinder.

The water being drawn through the perforations, a film of pulp adheres to the surface of the *former*, which is then raised from the vat, and, the coating of paper-pulp being removed and dried, forms a seamless article which requires no farther manipulation for most ordinary purposes, but for ornamental uses may be covered wholly or in part with a second coating of colored pulp, and embossed or otherwise ornamented by stamps, swaging, or perforation. See PAPER-MOLDING.

Pa'per-box Ma-chine'. A machine for making boxes from the roll or from blanks of paper.

Hatfield's machine, March 8, 1870, is designed for attaching the bottoms to cylindrical paper-box bodies previously formed by another machine. The shaft *a* is hollow, and through it works a spindle, operated by means of a hand-lever *c*, and carrying a fixed head or disk.

On the end of the shaft *a* is an expanding head *d*, formed in segments, which are pushed radially outward by links operated by a lever and arm.

f is a tube containing the bottoms of the boxes; these are pressed by the follower *g*, kept in contact therewith by a cord and weight *h*; *i* is a plunger cut-off by which the bottoms are pushed down one by one into contact with the follower *k*. This is advanced by a lever *l* operated by the hand-lever *c* through the medium of the rod *m*; *o* is a treadle connected by cranked arms and rods to the rock-shaft *p* of the lever *l*, and to the arm of a lever having a divided head in which a roller is journaled.

The head *d* is rotated by the pulley *r* on its shaft, and the treadle depressed; this throws the roller out of contact with the expanding head *d*, and also partially rotates the rock-shaft *p*, throwing the latch *l* into position to engage the plunger-rod *k*. A box-body is slipped over the expanding head, which is then expanded. The lever *c* is depressed, thrusting out the disk within the expanding head and bringing it into position to receive one of the bottoms which has been pushed down by the plunger cut-off *i*. By an upward movement of the lever the box-bottom is pushed into contact with the disk, which, by the same movement, is withdrawn and brings the bottom into contact with the box-body on the expanding head; a slip of prepared paper, pasted on one side, is applied to the junction, the treadle is released, bringing the roller in contact with the side of the box, the rotary movement of which winds the strip around it, where it is fixed by the roller and vibrating fingers on an eccentric.

G. L. Jaeger, February 25, 1873. In this machine, an address or label is imprinted and the box cut out and formed at one continuous operation. The paper passes first between the impression-roller *a* and the type-roller *b*, which is supplied with ink from the trough *c* by inking-rollers *d*.

Circular knives and creasers on the roller *g* cut it into the shape shown on the plan view during its passage between that and the roller *i*. Paste is applied to its edge by the rollers *k l*, in connection with a smaller roller not shown. Proceeding onward, two of the flaps are turned up and secured by pivoted wings *m n*, the other two being similarly treated by other wings, leaving the end flaps to be folded in by hand.

F. Gates, April 5, 1870. For making rectangular boxes. The

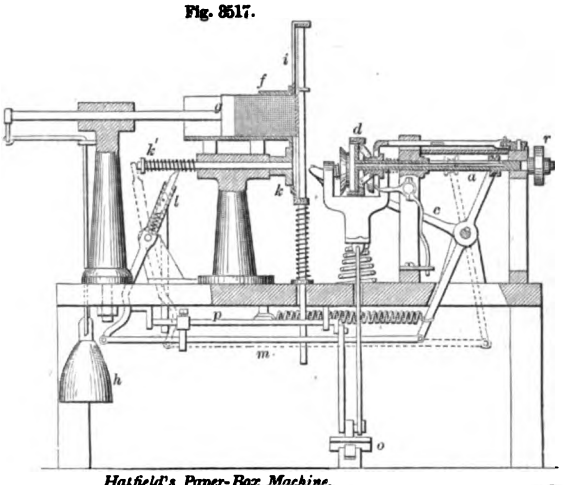
Fig. 3517.



Hatfield's Paper-Box Machine.

paper web from the roll *a* passes between the rollers *b c*, by the upper one of which paste from the trough *d* is applied to its edges. It is then carried forward by the feed-rollers *e f*, and the necessary slits cut by a vertically reciprocating cutter, after which it is subjected to the action of a plunger *h*, which shapes it by forcing it within one of a series of molds *i*, on an endless chain *k*, advanced intermittingly by a pawl *l* operated by an oscillating lever from the driving-shaft. The boxes are carried around by the endless chain until they successively arrive in a sufficiently dry condition at a point over an aperture, where they are forced out of the molds by a vertically reciprocating plunger *w*.

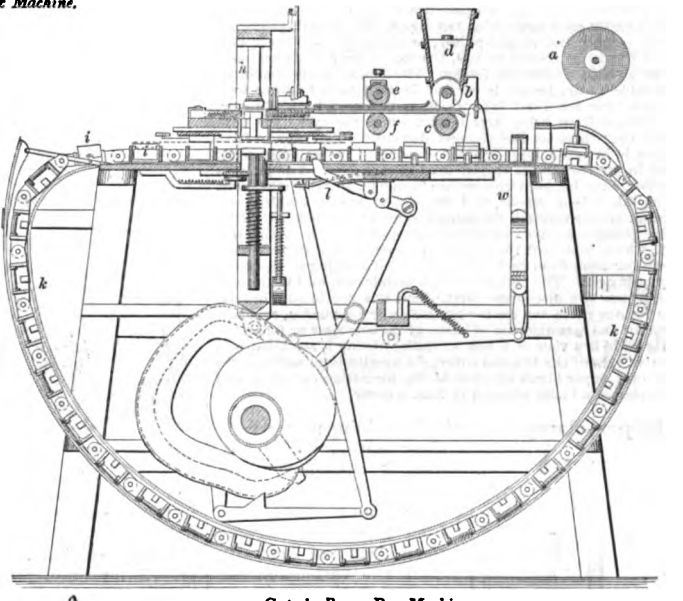
Foster, March 19, 1837. For making match and other tubular boxes. The previously cut blanks are fed upward by a follower, and pushed forward by a reciprocating feed-bar into the flaring mouth of a former, by which the paper is pressed into shape around the head of the feed-bar. It is drawn onward and delivered from the feed-bar by angularly placed rollers, which also turn down and finish the corners. The gumming or pasting is afterward done by hand.

Keating and Waymouth, June 8, 1869. For making and sanding match-boxes. The blanks, cut to shape, are advanced and gummed by means of a roller; each blank as it is gummed is carried forward to a die, through which it is forced by a descending plunger, uniting the gummed edges, and deposited in one of a series of receptacles on an endless conveyer, which carries it forward to a roller by which its bottom is gummed; it thence passes over a box containing sand, a portion of which is deposited on its bottom by a lifter, and is finally discharged by a plunger.

Heyl's patent, October 31, 1871, is for making and covering paper boxes, the flaps being secured by paste.

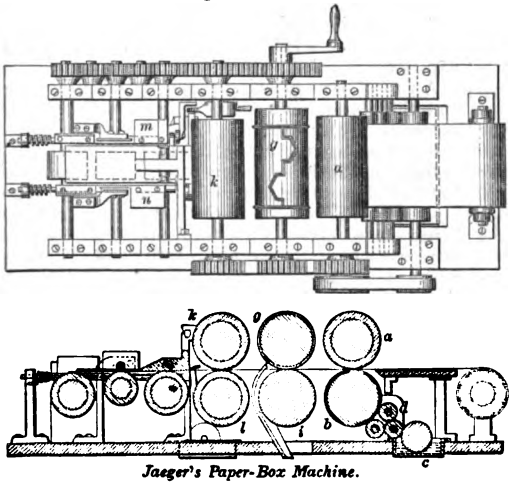
The pieces of pasteboard from which the boxes are to be made are placed directly over the machine in a box, from which they can be dropped one by one at each revolution of the machine, directly behind the crimping-frame or former, and in front of the reciprocating plunger. The plunger then moves forward, pressing the pasteboard through an opening in the *former*, which, being barely large enough to admit of its passage, bends the pasteboard close to the plunger, where it is held

Fig. 3519.



Gates's Paper-Box Machine.

Fig 3518.



Jaeger's Paper-Box Machine.

by a set of nippers attached to the plunger. The plunger then stops its forward movement a short distance in front of the *former* to receive the covering-paper. A strip of paper of sufficient length to go entirely around the box is inserted at the extreme right of the machine, and is caught by and carried around the pasting-wheel, which, in its return motion, transfers the paper to the pressing-wheel, pasted side out; from this wheel it is again transferred to the sides of the box by a forward movement of the pressing-wheel (until it rests against the box) and a revolution of a plunger. The box with the covering-paper around it is then carried forward by the plunger into the folding-frame, when the cover-paper is lapped around against the bottom of the box by a set of leaves or folders which move inward across the bottom as the box is pressed upon them. The plunger then returns to its first position, leaving the box in the folding-frame, which then rocks over into a horizontal position directly under the vertical plunger. The next operation is to fold the upper edge of the cover-paper over the top and down into the inside of the box. This is done by the inward and downward motion of the square-grooved feet of a vertical plunger as they pass down into the box. The label or square piece of paper for the bottom of the box is pasted by being laid upon the paste-roller, from which position it is thrown, pasted side out, up against a platform by a lifting-rack. Small

Digitized by Google

nippers or fingers attached to the platform grasp the label at either end and hold it against the platform, while the latter turns upward and brings the label immediately under the box. The box is then pushed down through the folding-frame upon the label that lies under it, and the label is made to adhere to the box by a firm pressure of the vertical plunger. This completes the operation, and the vertical plunger returns to its original position, leaving the finished box upon the platform, which in proper time again turns down and casts the box out at the end of the machine.

Patent 132,077 is an improvement on this, and patent 132,076 is a pasting and sanding device for the ends of match-boxes.

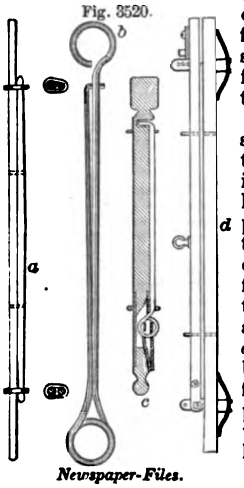
Heyl's patent for making wire-fastened paper boxes, October 8, 1872.

The machine is intended primarily for making boxes of paper or pasteboard without cement, the fastening being effected by wire staples, which are produced and applied by the machine which forms the boxes. The box-blanks are placed in a receptacle provided with a sliding bottom, which is drawn up by a weight and cord applied to a fusee-pulley adapted to graduate the power of the weight to correspond with the number and weight of the blanks remaining in the receptacle. The weight-pulley is detained by a ratchet, which prevents the drawing up of the sliding bottom, excepting when the said ratchet is retracted. The blanks are taken one by one from the top of the pile by a pneumatic or suction feeder provided with automatic valves to adapt it to seize and drop the blanks at the proper moments. The said feeder in its descent retracts the detent-ratchet and receives a slight upward pressure from the pile of blanks. As the feeder rises again with one blank, the detent, being released, catches the weight-pulley, so that, whether the quantity of blanks be greater or less, the top of the pile always rests at one level to receive the feeder. The blank, being deposited on a table by the feeder, is carried forward by a follower to a position over the mold, into which it is forced by a plunger, the bottom flaps being first bent up and the end flaps next folded over them as the plunger descends. The wire to form staples is in continuous lengths, contained on suitable reels, equal in number to the staples used in each box. The lengths of wire are cut off, bent into square form over suitable mandrels, which latter then recede, and the staples are, by sudden percussion, driven through the lapped sides of the box. Cavities in the plunger receive the inwardly projecting ends of the staples, which ends are then bent in opposite directions, either toward or away from each other, by slides working in the sides of the plunger. The plunger is then withdrawn, and its descent with a new box discharges that which was previously formed. The various parts are made changeable or adjustable, to adapt them for the manufacture of boxes of various sizes or forms.

Fig. 3516 is a view of a box so made, *j* being a sectional perspective view of the box and cover, *j'* a longitudinal section, *j''* a plan of a paper blank adapted for the formation of a box, and *j'''* a plan of a blank adapted to form a cover.

Pa'per-clamp. A device for holding newspapers, sheet music, periodicals, etc., in convenient form for reference, and at the same time preserving them from injury by keeping them clean and flat.

Fig. 3520.



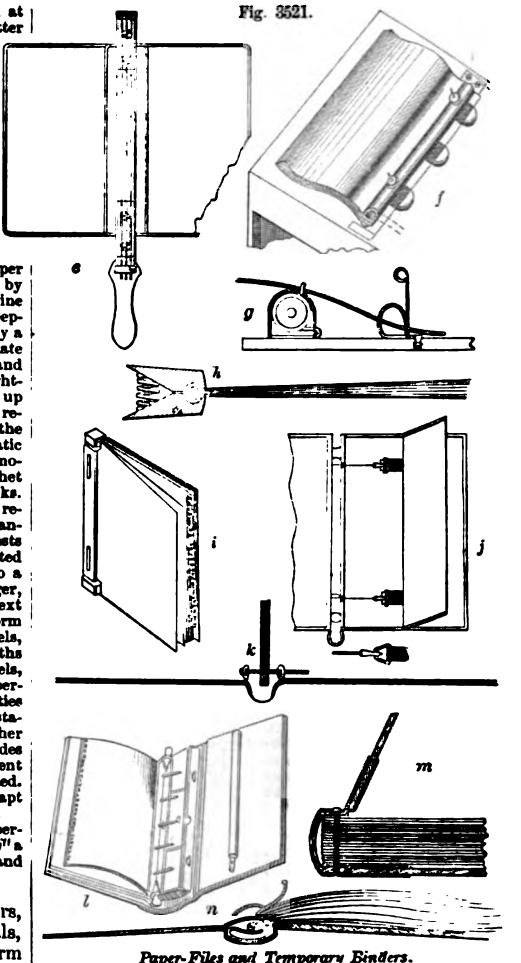
Newspaper-Files.

Of the various forms, some fulfill these conditions very imperfectly, being mainly intended to keep the issues of a newspaper together and keep them from being carried off or dropped upon the floor. Of these there are two kinds, the *portable* and the *desk-clamp*. *a b c d*, Fig. 3520, are portable forms, in which the folding edges of the newspapers are clamped between two bars or wires hinged together.

Fig. 3521 shows several forms, of which *e f g* are intended for desks.

h i j k l m n are all forms of temporary binders, in which the periodicals, papers, or sheet music are held by the folded edge, either by a simple clamp, as in *h i*; by cords, as in *j*; by impaling wires, as in the other figures, which need no lengthy explanation.

Fig. 3521.



Paper-Files and Temporary Binders.

Pa'per-clip. A clasp for holding papers together. A means of filing bills, letters, etc. It may be, —

A suspensible hook on which the papers are strung.

A wire on a stand or suspensible, on which the papers are impaled.

A pair of jaws grasping papers, as with the finger and thumb, and intended to lie on the desk or be suspended by a ring.

See also PAPER-CLAMP; PAPER-FILE, etc.

Pa'per Cloth. A fabric patented in England in 1843 by Henry Chapman. It is prepared by winding cotton, linen, or other cloth upon a roller, which is introduced between the third press-felt of a Fourdrinier machine; between this roller and the endless felt is placed a trough containing an adhesive solution, which is, by means of a roller in a trough, applied to the cloth; at the same time, the continuous sheet of paper formed by the machine in the usual manner is carried forward, meeting the cloth, and the two passing together through the pressing-rolls are caused to adhere. By reversing the cloth, a similar paper facing may be given to the other side.

Pa'per Collar. One made from paper in imitation of linen. Before the advent of the factitious

Digitized by Google

article, made as an object of merchandise and so much worn, collars were occasionally made of paper, either as by Lord Byron, who affected a collar of peculiar shape, somewhat on the sailor pattern, or by mountebanks and wandering minstrels of the colored persuasion. The festive collars of "Brudder Bones" and his partner on the left wing were exaggerated turn-downs or chokers made from cardboard.

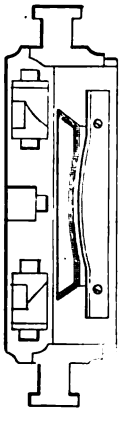
The first patent on a collar concerned its shape, and is somewhat curiously described. It was of fabric, and was called the "Belvidera" collar, patent to Cantelo and Kerrison, November 19, 1833.

"The band has a breadth equal to the length of the wearer's neck. Its lower edge is cut curving down in the center, to cover the cricoid cartilage and the thyroid gland, and curving upward on each side to avoid pressing the clavicle and the sterno-cleido-mastoideus muscle. The upper edge of the band proceeds upward on each side from the center in a line corresponding with the inclination upward of the lower jawbone to a point under the angle thereof, and thence downward at a nearly equal angle, so as to avoid pressure of the mastoid process of the temporal bone. A small oval piece of a size according with the parts to be fitted is cut out of the center of the upper edge of the band, so as to give room for the angle of the thyroid cartilage or pomum Adami."

(Nothing like being precise !)

In 1854, Walter Hunt, after his unsuccessful suit with Howe in the matter of the sewing-machine, confidently asserted to an intimate friend, "I will make a machine which will imprint a stitch more perfect than that of the sewing-machine." The paper collar with an imitation stitch made by an indented tool was the result. Long experiments upon paper, its combinations with cloth and combined fabrics attached by means of paste, followed. The article he put upon the market consisted of thin white cotton muslin, coated upon both sides with a very thin white paper. The face was enameled and polished by calendering. The collar was cut out in several pieces, after the manner of the old cheek-piece standing collar, being in every respect similar, except in material and stitches. The collar was made, like its linen predecessor, in three pieces, united by eyelets, and was fastened by strings. It was coated with colorless, transparent, water-proof varnish.

In 1856, he united two thicknesses of cotton cloth, bleached, sized, and calendered, and fashioned into collars. He was also the first to produce a substitute for the linen collar which had the necessary rigidity, imitation stiffening embossed thereon, and holes punched therein, forming a merchantable article.



In 1857–59, W. E. Lockwood, having purchased the effects of Hunt, added the farther improvement of producing a paper-faced fabric having embossed upon its surface, by means of an electrotype die taken from the fabric itself, an exact imitation of the warp and woof of the fabric, and also of the stitches which constituted its embroidered pattern. This ornamented surface is produced upon all paper collars now in the market. Lockwood also printed fanciful designs on the face of collars, in imitation of calico fabrics.

In 1863, the button-holes, which had formerly been simply punctured, were reinforced by cloth patches by an English maker.

In 1863, Gray of Boston rolled a garrote collar from a single piece of paper, so as to make the standing lappel flare from the neck. He also turned a Byron collar upon a defined curved line, so that the outer portion would have the larger curve, and to avoid puckering the material, and also to provide for the neck-tie.

Evan, in the same year, improved the paper for collars by constructing it of long-fibered stock.

Lang, in 1866, made paper collars and cuffs in imitation of lace.

In the same year, Alden made them of the proper flaring form direct from pulp.

Lockwood, in 1869, embossed coarse cotton sized cloth by means of linen cloth under pressure.

Paper collars are made in several ways : —

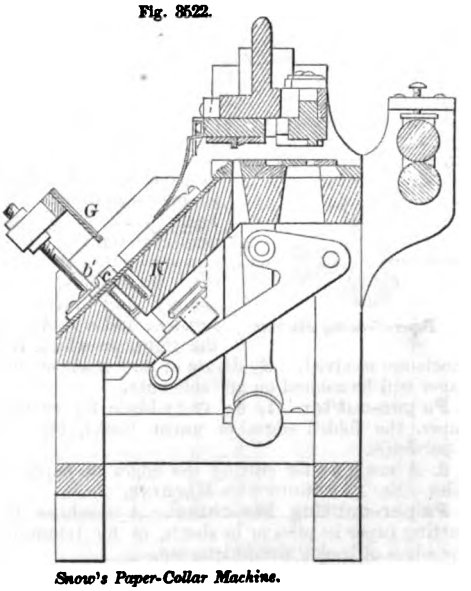
1. They are cut out of piles of sheets, in the same manner as envelopes, by means of a properly shaped knife in a platen press ; the resulting blanks are embossed, button-holed, folded, and curved for the neck by other machines.

2. The collar is cut, button-holed, and creased for folding by passing through a pair of rotary compound cutters and dies.

3. The collar is made by machines which automatically complete the collar for wear from a web of paper. A good example of this is Snow's machine.

Fig. 3522 is a view of Snow's patent of 1865. The paper is intermittingly fed forward by rollers the width of a collar before each descent of the platen,

Fig. 3522.



Snow's Paper-Collar Machine.

which carries, arranged in proper relative position, (1) a set of end knives and end and middle button-hole punches, all adjustable to cut different-sized collars ; (2) a die having serrated teeth to emboss imitation stitches, which is detachable ; and (3) a knife, also adjustable, the front and rear edges of which may be of different curves, for cutting the upper and lower edges of the collar. The bed has corresponding intaglio cutting-dies and a duplicate embossing-die, so as to ornament both sides of the collar. As the ends and button-holes are being cut for one collar, that next in advance is being embossed with stitches, while the forward one is severed from the sheet and slides down the inclined table between end guides until it rests against the stop *b'*. In this position it is struck by the folding-blade *G* and pushed through a slot, resting on a

Digitized by Google

shelf until it is carried endwise out of the machine by the belt *K* between it and one of the pressing-rolls *c*, which curves it and completes it for wear.

In finishing the blanks, in lieu of several machines performing individual operations, a machine made by Denison carries the blank through the machine, finishing it at successive stages.

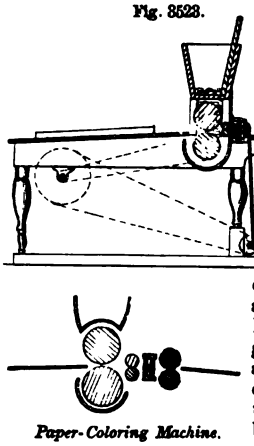
The proper points on the collar are moistened; patches are cut from glutenized cloth strips, and pressed on the moistened spots; through these reinforced points the button-holes are punctured; the crease for folding is indented; the embossed stitching is impressed, and the collars ejected.

At the present time, Denison and Snow have in operation machines which cut the blanks from webs of paper without the slightest loss of stock; while Snow also produces by a novel machine nearly all of the combined cloth and paper used in the collar trade at the present time.

The principal manufactories are at Springfield and Boston, Mass., New York, and Philadelphia.

Pa'per-col'or-ing Ma-chine'. One in which the paper is fed in sheets between color-rollers which give it a coat of color. The example has an upper reservoir for the coloring matter, and another placed below the rollers, so that both sides of a sheet of paper may be colored at one operation. The lower view is a diagram of the moving parts, and shows the color-rollers, feed-rollers, stationary and revolving brushes, and a table, on the right, on which the sheets are received. By disuse of one reservoir the paper will be colored on one side only.

Fig. 3523.



Paper-Coloring Machine.

Pa'per-cut'ter. 1. An ivory blade for cutting paper, the folded edges of uncut books, etc. A *paper-knife*.

2. A machine for cutting the edges of paper in piles. See PAPER-CUTTING MACHINE.

Pa'per-cut'ting Ma-chine'. A machine for cutting paper in piles or in sheets, or for trimming the edges of books, pamphlets, etc.

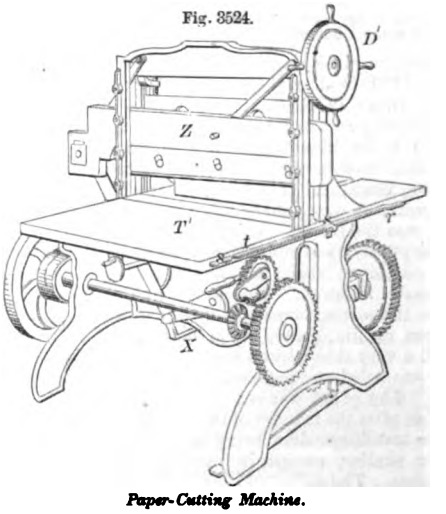
Owing to the sizing and coloring matter, paper is a very difficult substance to cut, and requires a strong knife to pass through any considerable quantity. The knife must also have a draw or shear cut, and requires frequent grinding.

One form of paper-cutter is a straight-edge and traveling knife. Another has a revolving traveling knife sliding on a bar parallel with a stationary knife which acts as one blade of a shears.

Another form has a knife hinged at one end, which descends on a pile of paper with a shear cut. See CARD-CUTTER.

Sanborn's paper-cutter (Fig. 3524) has a cast-iron frame which sustains the horizontal bed *T'* upon which the paper to be cut is placed. Working through vertical slots or guides, formed in the upper part of the frame just mentioned, is the knife-stock *Z*, which carries the knife or cutter, the latter being detachable, so that when required it may be removed for sharpening. The cutter-stock is suspended from a horizontal cross-piece at the top of the frame by means of two toggles or swinging-bars, which, when the cutter-stock is elevated, as shown in the engraving, occupy an inclined position. The cutter-stock is connected by a pitman with a crank arranged underneath the table, and rotated when the apparatus is in use by a belt-wheel operating through a suitable system of gearing, and arranged at one side of the frame; this belt-wheel being furthermore furnished with a suitable balance-wheel. The table is made adjustable under the cutter by suitable appliances worked by a crank, and has a gage *t s r* arranged at one edge and in suitable proximity thereto, so as to guide the attendant or operator in regulating the position of the mass of paper upon the table and in relation to the cutter. The clamp for clamping the paper tightly in place upon the table, previous to and during the descent of the cutter, is operated by appropriate devices, to which movement

Fig. 3524.



Paper-Cutting Machine.

is given by a hand-wheel *D'* arranged at the side of the upper portion of the frame.

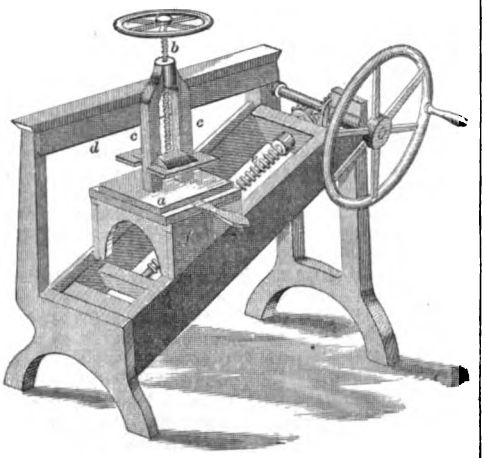
The mass of paper having been properly placed upon the table and underneath the cutter, as just above indicated, the driving-belt is shipped to turn the driving-pulley and rotate the crank *X* which operates the cutter-stock. As this latter is drawn longitudinally inward by the action of the pitman, the suspending bars or toggles are brought into a more or less vertical position, thus forcing the stock and its attached cutter downward, and consequently giving a compound downward and longitudinal motion to the same, which insures the gliding cut essential to the perfect working of a machine of this character. As the crank completes its revolution the pitman is of course forced outward, thereby bringing the cutter-stock upward and outward to its original position, preparatory to a repetition of the cutting operation.

Soule's undercut machine has the knife below the bed, and the knife lifts with a shearing cut against a pile of paper held down on the bed by a clamp. The portion of the bed or table outside the knife is attached to the knife-carrier in such manner as to yield sufficiently to receive the part of the paper cut off. The knife moves only far enough to cut through the paper, instead of passing through its whole stroke, as in guillotine machines.

Digitized by Google

Semple's paper-cutter (Fig. 3525) is used for trimming the folded edges of books and magazines after the sheets are stitched. Two bundles of books are

Fig. 3525.

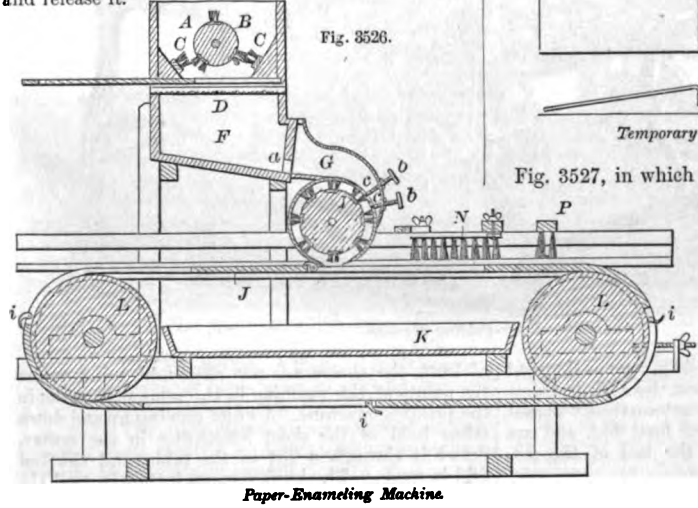


Paper-Cutting Machine.

placed on platform *a* with their backs to the standards *c c*, and are held down by the screw *b*. The platform is then drawn up the inclined track by the action of worm-gear *e*, and the sheets are brought against the knife *d* with a drawing cut. Platform *a* is pivoted to carrier *f*, and revolves to present the top, bottom, and sides of the books to the knife.

Pa'per-en-am'el-ing Ma-chine'. In Fig. 3526, the enameling mixture is thoroughly stirred within the chest *A* by stationary and revolving brushes *B C*; falling through the diaphragm *D* to the chamber *F*, it passes through the gate *a* to the spout *G*, whence it is admitted by the adjustable screw-valves *b c* to the brush-roller *I*, rotating within a cylinder having an opening at its lower side, through which the brushes spread the enamel on the sheet of paper passing along on the endless belt *J*. This is revolved by two cylinders *L L*, having fingers *i i*, which clutch the sheet when presented to them, and after carrying it past the spreaders *N* and blenders *P* fall and release it.

Fig. 3526.



Paper-Enameling Machine.

Pa'per-feed'er. A device for delivering paper singly in sheets to a printing-press, ruling-machine, envelope-cutter, paper box or bag machine, etc.

Sheets are frequently fed to a press or ruling-machine by hand; the pile lies on a feed-board, and the sheets are thrust forward against a guide by a slight blow, the grippers or feed-rollers then seizing the sheet by its edge and carrying it over the guide.

A form of pneumatic feeder has a number of suckers exhausted by an air-pump. The suckers raise the edge of the top sheet, when a puff of air prevents other sheets from following. The edge of the lifted sheet is brought parallel with the grippers, which then carry it to the press.

One form of feeder uses a revolving brush, which sweeps the top sheet from a pile against guides. As the pile diminishes in hight, it is raised by springs underneath.

File-cut fingers to draw a sheet by friction to positive grippers are also used.

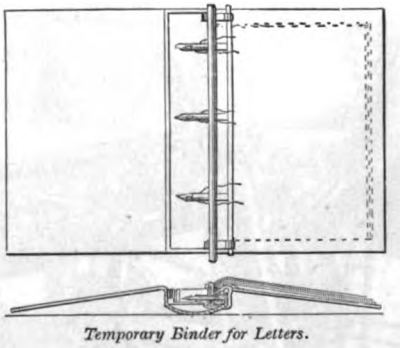
Envelope and paper-bag machines sometimes seize their sheets by a gummed roller or claw. The gummed surface of the paper is utilized in the subsequent folding of the parts together.

Fig. 3527.

Letter-File.

Pa'per-file. A device to hold letters or other papers in a pack. Among the many forms may be noticed: —

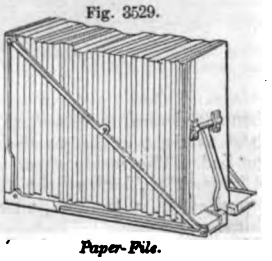
Fig. 3528.



Temporary Binder for Letters.

Fig. 3527, in which the papers are pressed upon a bottom board by a spring follower above.

Fig. 3529.



Paper-File.

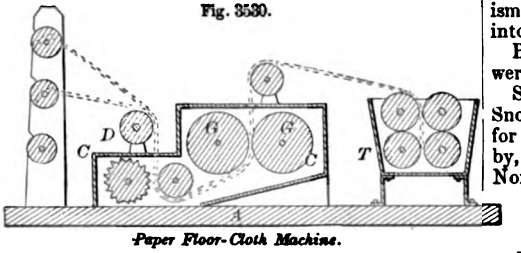
Fig. 3528, in which letters are impaled by their edges and held in a case or temporary binder.

Fig. 3529, in which the boards of the files are made to fold together, and are held at a right angle when opened, by a pointed brace. The follower is jointed to a bar whose lower end slides and clamps in a longitudinal, under-cut groove. See also PAPER-CLAMP; LETTER-FILE.

Pa'per Floor-cloth. An artificial cloth, used as a substitute for oil-cloth for floor covering and other purposes. It usually consists of a thick sheet or associated sheets of paper treated with paints or varnish.

Fig. 3530 is a machine for converting two sheets of paper into parchment-paper by passing them

Fig. 3530.



Paper Floor-Cloth Machine.

through dilute sulphuric acid and uniting them so as to form a compound sheet suitable for floor coverings, belting, etc. The two webs pass conjointly over the roller *D* to a second roller working against a toothed perforator, which assists in uniting them, this part of the operation being completed by the rollers *G G* in the acid-box *C C*. It is afterward washed by passing between rollers in a water-trough *T*.

Pa'per-fold'er. A bone knife used in folding paper, folding signatures for sewing, and feeding paper from the *bank* to the press.

Pa'per-fold'ing Ma-chine'. A machine for folding printed sheets preparatory to binding.

J. S. Gallaher completed a folding-machine in 1843, deposited a model in the United States Patent Office, and published a description in the Baltimore "Sun." It embodies a vibrating blade, folding a sheet through a slit in the feed-table into the bite of rollers, from which it is carried by endless bands to a second knife between a second set of folding-rollers, and finally deposited in a trough.

Birchall's English patent of 1847 shows mechanism for folding the sheet by a reciprocating knife into folding-rollers.

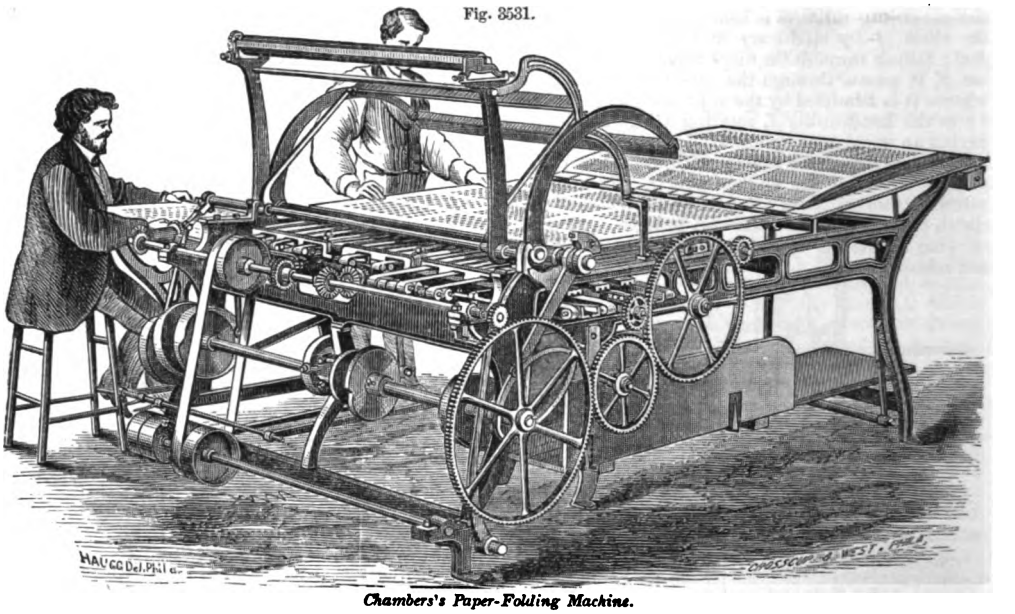
Black (English), 1850, had registering-pins, which were vibrated out of the sheet.

See also Smith's patent, November 27, 1849; Snow, October 15, 1850; English patent No. 13,315, for 1850; North's patent, October 15, 1856; Crosby, December 23, 1856; Smith, May 19, 1857; North, August 10, 1858; Endriss, March 8, 1859.

Chambers, 1856, had registering-pins to fit the perforations made by the printing-press. (See POINT.) These pins or points are adjustable, and, as the folding-blade descends, recede by a cam movement.

Chambers's machine (Fig. 3531) is adapted to fold large double-sheet papers. The sheet to be folded is spread upon the folding-table, and the register secured by points. The folding-blade overhead falls on the middle of the sheet and carries it down, doubled, through a slot in the table. The blade is

Fig. 3531.



Chambers's Paper-Folding Machine.

then withdrawn, and a second fold given the doubled sheet at right angles to the first, by a blade below the bed. The inside sheet is automatically placed in its position, both receive their final fold, and are deposited in a trough under the bed of the machine.

In a machine exhibited at the London Exposition of 1862, the sheets are put singly by a boy under the points of the machine in the same manner as in the printing-machine. A knife moving up and down takes hold of the sheet lengthwise in the center, draws it through a slit in the table, and the first fold is made. The knife returns instantly, and the sheet is taken by a second vertical knife, folding it

Digitized by Google

at right angles to the first fold. Before the third fold is made the stitching operation commences; two needles, provided with hooks, passing through the middle of the sheet about an inch distant from each other, draw through the cotton unwound from a bobbin and cut to the required length. The sheet is then folded a third time by a knife acting at right angles with the second one, which takes hold of the sheet and pushes it between a pair of ribbed rollers, whence it passes directly to another pair of polished rollers, and is deposited on the table.

Ford's combination of a folding-machine with a printing-press (1872) is arranged so that the flyer of the press will deposit the papers upon tapes instead of on the ordinary tables, the papers being thence, by and upon the tapes, conveyed to the folding apparatus, and there folded as rapidly as they are printed. See FOLDING-MACHINE.

Pa'per-gage. (*Printing.*) An instrument for measuring the type-face or *measure* of printed matter and the width of margin. It is usually a squared stick on the sides of which are numbered columns of the different sizes of type.

Pa'per-hang'ing. The art of covering walls with decorated paper. The sheet of paper is unrolled, cut to a proper length, the edge trimmed, a coat of paste applied to the back and one end of the piece attached to the upper part of the wall, the lower part hanging suspended thereby; the workman then lightly dabs the face of the paper with a cloth, commencing at the top and working downwardly until he reaches the bottom, causing its adhesion to the wall and insuring a smooth surface. When the wall has been covered in this way, a narrow slip is pasted around its upper edge, concealing the ends of the pieces and serving for ornament.

The name is derived from the tapestry hangings, for which it forms a substitute.

The art originated in China, where it has been in use from time immemorial. England appears to have been the first European country into which it was introduced; Lanyer, 1634, having obtained a patent for a velvet paper surfaced with a short, dyed, woolen flock, which adhered to figures printed in glue on the paper. This invention was also claimed by several Continental inventors.

Fig. 3532.

Paper-Knife.

Among the kinds of paper-hangings may be cited: —

That simply printed in colors by stencils, blocks, or cylinders.

Flock paper, having a thick covering of woolen stuff, chopped fine and dyed. This adheres to the required portions, which are printed in glue.

Metallic-dust paper, in which flattened specks of metal are caused to adhere to the figures on the paper. See WALL-PAPER.

Pa'per Hot-press. This was invented by Turnbull of England, who adapted the press then used for packing and hot-pressing cloth to the purpose of hot-pressing paper. Noticing the damp and uneven character of the printed work, he placed some circulars between the hot iron plates, and brought down the heavy screws upon them. He then started the business which his descendants retain.

Pa'per-knife. A blade of ivory, mother-of-pearl, or bone, used in cutting leaves of books, folding sheets of paper, etc.

The illustration shows one with an ivory blade riveted to a tang, which is socketed in a vulcanite handle.

Pa'per-mak'ing Ma-chine'. The history of paper is considered under the caption PAPER (which see). The making of paper by machinery commenced near the close of the last century. Previous to this time paper had been made in hand-molds of wire, which molds were made by hand of wires laid parallel and secured at intervals by a fine wire binding. This could be readily made of sufficient size for such sheets as were then required, and the paper of that day shows by its margin the mark of the *deckle*.

The following will indicate the succession and dates of the inventions in the line of paper-making machines. Some collateral points of interest are also noted: —

1750. Woven paper-molds introduced by Baskerville.

1759. The rag-engine introduced into England from Holland, where it was invented about 1750.

1790. The practice of bluing paper is said to have originated about this time from the circumstance of an English paper-maker's wife having accidentally dropped her blue bag into some pulp in an advanced state of preparation.

1798. Louis Robert, a workman in the establishment of Didot, at Essone, France, announced that he had discovered a way of making sheets of paper of large size by machinery.

1799. Paper in an endless web actually made by Robert.

1800. 8,000 francs awarded by the French government to Robert for his invention, and leave granted him to take his working model to England.

1801. John Gamble, an Englishman, who had accompanied L. Didot from Paris with Robert's machine, obtained a patent therefor in England.

Matthias Koops made paper from straw, wood, and other vegetable matters without the addition of other paper stuff. He also discovered a process for extracting ink from old paper.

1808. Bryan Donkin produced a self-acting paper-machine on Robert's plan. He had been employed by Didot and Gamble for this purpose, and appears to have made great improvements on the original.

1804. Henry and Sealy Fourdrinier of London purchased the patents of Didot and Gamble. From the improvements made under their auspices and their manufacture of it on an extensive scale, it received the name of Fourdrinier machine, by which it is generally known.

1805. Donkin altered the position of the cylinders, and by dispensing with the upper web simplified the machine and enabled it to perform a greater amount of work.

1806. Francis Guy of Baltimore obtained a patent for paper carpeting.

1809. The cylinder machine invented by Dickenson, an English paper-maker.

1817. High glazing introduced by Heath; also English cardboard manufacture.

1819. The London Society of Arts and Manufactures awarded thirty guineas to Mr. Finsley for the invention of ivory paper.

1821. T. B. Crompton in England obtained a patent for drying and finishing paper by means of a cloth against heated cylinders, and the application of a pair of shears to cut the paper into suitable lengths as it issued from the machine.

1826. Canson in France applied the system of rarefying the air beneath the web, used in the Dickenson cylinder machine, to the Fourdrinier machine.

1827. Canson invented a method of sizing pulp in the vat, using wax as a basis; Delcambre in the same year employed a size having rosin as a basis; and Obry conceived the plan now generally adopted in France of using rosin and alum dissolved in a solution of soda and combined with potato starch, for the same purpose.

1828 George Dickenson patented an improvement in paper-machines, consisting in giving an up-and-down movement to the paper instead of the shaking lateral movement imparted to the wire web of the Fourdrinier machine, which tended to form longitudinal streaks or ribs in the paper.

A similar contrivance was also introduced by Donkin.

1828. Professor Cowper patented in England a paper-cutting machine which served as a basis for subsequent improvements.

Richard Waterman and G. W. Annis, of Providence, R. I., patented a method for making double paper by bringing a sheet previously formed in contact with the stuff on the belt and passing both between press-rollers; any number of thicknesses, it was claimed, might be combined in this way.

Crompton and Miller patented a method of cutting an endless web of paper lengthwise by means of revolving blades on a rotary shaft.

Mason Hunting, of Watertown, Mass., patented an improved top press roller, adjustable so as to form paper of any desired thickness by a single operation.

Marsden Haddock of New York obtained a patent for a machine for making paper by dipping, as in the hand-process

1829. W. Dobit, of East Hartford, Conn., patented a machine for cleansing and preparing rags for use in paper-stock.

Isaac Saunderson, of Milton, Mass., patented a horizontal whirl-wheel and sheet-forming rollers in connection with the cylinder machine, to cause a more uniform felting of the fibers,

Digitized by Google

insure equality of strength in both directions of the paper, and enable thicker papers to be made

Reuben Fairchild, of Trumbull, Conn., patented an agitator, a semicircular cylinder in the vat vibrating transversely to the making cylinder, for the same purpose.

Thomas Cobb of England patented a method of tinting paper and embossing it during the process of making by passing it between engraved rollers, also surfacing paper with silk, velvet, or other fabric.

1830. A sheet of paper 13,800 feet long and 4 feet wide was manufactured at Whitehall Mill, Derbyshire, England.

Richard Ibotson patented a device for separating from the *stuff* the knots which had passed the strainer. These had previously been picked out by hand.

In England, John Hall patented a mode of introducing water to the vat, by which a considerable pressure was effected on the exterior of the cylinder, causing the pulp to adhere more firmly thereto.

John Wilks added a perforated cylinder to the Fourdrinier machine to facilitate the escape of water from the web previous to its passage through the pressing-rolls; and Dickenson patented a machine for forming a double-web paper by uniting the web in process of formation with a sheet previously formed. Thomas Barratt obtained a patent for a means of impressing the water-mark and maker's name in continuous paper, so as to resemble that made by hand Thomas and Woodcock, of Brattleboro', Vt., patented a pulp-dresser; and Thomas Gilpin, of Philadelphia, a paper-calendering apparatus.

1831. J J. Jaquir obtained a patent for making continuous paper with wire-marks similar to hand-made paper.

Edward Pine, of Troy, and E. N. Fourdrinier patented apparatus for cutting continuous paper into lengths; and Turner, a strainer designed to supersede the agitating vat of the Fourdrinier machine. Carvil, of Manchester, Conn., patented a screen with fans; and John Ames, of Springfield, Mass., introduced a wire cylinder for the purpose of cleansing rags.

1832. James Sawyer, of Newbury, Vt., invented a piston pulp-strainer; John Ames, a sizing-machine.

1852. G. W. Turner, London, England. Improved mode of applying an endless wire-web in a paper-machine; also, mode of passing the paper through a trough of size between two endless felts.

1853. Brown and McIntosh, Aberdeen, Scotland. Hollow perforated mold, covered with felt, to which the pulp is caused to adhere by rarefaction of the contained air.

1853. Machine patented in England for preparing wood for making paper.

1856. Horace W. Peaslee, Malden Bridge, N. Y. Drying cylinder for paper-machines, comprising spiral tubular heater, non-conducting cylinder, and exterior metallic casing.

V. O. Balcom, Bedford, Mass. Revolving pulp-tub with grooved grinding roller rotated therein at a different rate of speed.

Thomas Lindsay and Wm. Geddes of Connecticut. Varying the width of paper while the machine is in operation by forming the trough which delivers pulp to the web in two parts, sliding one over the other and varying the distance apart of the *deckle-straps*.

1859. M. L. Keen, Roger's Ford, Pa. Paper-stock boiler for ligneous matters.

Martin Nixon, Philadelphia. Boiler for treating paper-stock under pressure by the action of upward current of steam and downward current of hot alkaline solution.

Crocker and Marshal, Lawrence, Mass. Combination of drying-cylinders, moistening apparatus, and calender-rolls for finishing paper.

1860. Jordan and Kiney (reissued patent). Conical grinder and case having induction and eduction pipes for rags and size.

C. S. Buchanan, Ballston Spa, N. Y. Rotary boiler with cylindrical concentric strainer and hollow trunnions, for treating paper-stock.

Gelston Sanford, New York. Pulper with conical ribs and serrated rubbers.

A. Randel, New York. Rag-machine with differential rolls, shredding cylinder, and spiked concave.

A. S. Lyman, New York. Separating fibrous matters by subjecting them in a close vessel to the action of an apparatus for beating, rubbing, grinding, or picking, and water at high temperature and pressure.

1863. E. G. Rutledge, Dayton, O. Creating a current in the vat in the direction of the pulp-cylinder.

J. F. Jones. Means for conveying away water from the interior of the *making* cylinders through hollow journals.

John Cowper, England. Rag-mill comprising endless feeder which feeds the material to fluted rollers that deliver it to a toothed rotating cylinder.

J. F. Jones, Rochester, N. Y. Machine by which a number of continuous webs may be made, or they may be united to form pasteboard.

M. L. Keen, Roger's Ford, Pa Pulp-boiler with perforated diaphragm, discharge pipe and valve for blowing out the contents under pressure.

Ladd and Walsh, New York. Boiler for treating fibers with or without alkali, having a perforated diaphragm for keeping the mass submerged during the process.

The Fourdrinier machine, as improved by Bryan Donkin and subsequent inventors, is illustrated in Fig. 1, Plate XXXVII. That shown, built by George Bertram of Edinburgh, is what is known as an 80-inch machine, that is, the endless web of wire cloth on which the pulp flows is 80 inches wide and 33 feet in length, capable of forming paper over 6 feet wide after trimming the edges, and of indefinite length. The whole machine is about 68 feet long. The operation is as follows: —

Pulp from the beating-cylinder is admitted to the chest *a* through a strainer *b*, consisting of a sheet of metal through which strips are cut; it is here constantly agitated by a stirrer *c*, and is caused to flow into a second and smaller chamber provided with a similar stirrer, which delivers it (after passing over a channeled plate by which extraneous matters of greater specific gravity than the pulp are arrested) on to the endless wire web or apron *d*; to this a shaking movement is imparted, distributing the pulp-fiber evenly over its surface. It is supported on a series of small rollers, and the width of the paper is governed by deckle-straps *e* at each side, which are carried by rollers *f f*, their tension being regulated by the arrangement shown at *g*. *h* is a vacuum-box from which the air is partially exhausted by a set of air-pumps, and which withdraws in part the moisture from the paper as it passes over the box. It is then carried between the cloth-covered rollers *i i*, by the lower one of which and the rollers *j j j* the wire-apron returns to receive a fresh supply of pulp, the paper being transferred to the blanket felt *k*, which conveys it to the press-rolls *l l*; these are solid, and over the upper one is a thin edge-bar, which removes adhering particles of fiber from the roll, and also serves to arrest the progress of the paper should it stick to the roll, thus preventing injury to the blanket. There rolls are adjusted in their bearings by the screw *m*, so as to exert greater or less pressure. The blanket then conveys the sheet to a position where it may be received by the second press-rollers *n n*, which farther compress and expel the moisture from it, and the blanket returns by way of the rollers *o o o* to the point whence it set out. After passing the press-rolls, the paper is received on a second endless blanket, which carries it to the first of a series of steam-heated cylinders, 1 2 3 4 5, between which it is partially dried and conveyed between other pressure-rollers *s*, and thence to a second set of drying-cylinders 6 7 8, whence, after being subjected successively to the pressing and stretching action of the rolls *p p*, it is delivered on to the cylinder or reel *f*. Registering mechanism indicates when a certain quantity has been delivered on to the reel, which is then removed and a fresh one substituted.

The number of drying-cylinders in a machine of this class may be indefinitely increased. In some cases more than 100 are employed, the object being to allow the sizing material to become thoroughly incorporated and to form a product resembling hand-laid paper in quality.

Dickenson's patent of 1847, improvement on patent of 1830, is for an arrangement so that the upper side of the double sheet, that which has not been in contact with the wire grating of the making-cylinder, shall be brought in contact with the metallic press-roll, and in the use of an exhaust-trough between the first and second press-rolls.

In Fig. 2, Plate XXXVII., *a a'* are the two making-cylinders; *b b'*, the couching-rolls. From these the paper is taken by the endless felt *c* to the first press-rolls *d d*, where it is slightly pressed between the felt *c* and another felt *e*, which revolves around the upper press-roll; the paper is then detached from the first felt and led upon another endless felt *f*, which conducts it to the second press-rolls *g g*, where it is farther slightly compressed, and after passing over the guide-rolls *h h* is carried to the third set of rolls *i i*, where a greater pressure is imparted, and thence to the steam-heated cylinders *j j'*, where it is dried and finally wound upon the reel *k*. *l* is the exhaust-trough; it is connected by a pipe with an air-pump, and has rollers for supporting the paper passing over it on longitudinal partitions adjustable to the width of the paper.

In the same patent Dickenson describes a modification of his machine for making triple-webbed paper, the face consisting of a ready-made sheet wound upon a reel to which the others were applied during their joint passage between the press-rolls.

In Scanlan's paper-making machine, the cylinder and Fourdrinier machines are combined for the purpose of making a double-webbed paper. The two webs may be of different texture and color.

In Fig. 3, Plate XXXVII.

u, drip-water guard, heated by steam from *z z*.
v, junction felt.
x, guide-roller for sheet.
y y, second pressure-rollers.

The two webs pass from each machine in the direction indicated by the arrows between the rollers *j w*, and are united by the pressing-rollers *m m*, the final pressure being given by the rollers *y y*.

The advantages claimed are that a less quantity of pulp may be used, requiring a less vacuum under the wire apron of the Fourdrinier machine, and causing less strain upon it; that, the backs of the two sheets being united, an equally hard, smooth face may be formed on each side of the paper, and that any defective parts in either sheet are covered by the other.

Either the cylinder or Fourdrinier part of the apparatus may be separately used, if required.

In Jones's pasteboard machine (Fig. 4, Plate XXXVII.) the web formed by the first cylinders at *k'* passes the rolls *l l'*, and first press-rolls m^1 m', and is united between the rolls l^2 l^3 with the web formed by the second pair of cylinders at a^1; the combined web passes through the rolls m^2 m^3, and is united between l^3 l^3 with the third web formed by the cylinders at a^3, and so on, successively taking up the webs formed by each pair of cylinders until the combined sheet passes through the press-rolls l^7 l^7, and is conducted through an opening in the floor above to the press-rolls m^7 m^7, which convey it to the drying-cylinders p^1 p^1, p^2 q^2 and calendering-rolls s^1 s^2, etc., on emerging from which it is carried between the final set of calendering-rolls t^7 to t^7, and thence to a cutting apparatus consisting of a fixed knife and a vertically reciprocating knife working in guides 10, which cut it into sheets. These are delivered singly by an endless band *y* on to a fly which deposits them one by one as fast as cut on a receiving-table. Each of the webs which combine to form the board may, if desired, be kept entirely separate from the others, by winding on the rolls *q q* after passing through its own press-rollers; or the thickness of the board may be varied by connecting together two, three, or more of the webs independently of the rest; or some of the making-cylinders and couchers may be thrown out of action.

Field's machine (Fig. 5, Plate XXXVII.) is of the cylinder class, and an endless wire belt is employed in combination with an endless felt. *a* is the vat, *b b* the making-cylinders, *c c* the couchers. The web passing between the cylinder and coucher is conveyed on the under side of the felt *d* to the squeezing-rolls *e f*, the lower one of which is arranged to the left of the upper, so that the water expressed from the web may not flow back and remove the pulp from the felt. The web, thus partially dried, passes under the wire-cloth and between the pressure-rolls *h i j*; the final pressure being applied by the rolls *o o*.

This invention is particularly designed for manufacturing straw-board and other thick papers.

In Harris's double-cylinder machine (Fig. 6, Plate XXXVII.), the left couching-roller *a* is placed at the left of the making-cylinder *b*, a gauze-covered roll *e* and solid roll *h* receive the single web from the right-hand cylinder *b* and coucher *a'*, from whence it passes by the apron *f* between the left-hand cylinder *b* and coucher *a*, and is united to the web formed thereon.

Vertical agitators *w* are provided at each end of the tank *n*, instead of horizontal agitators between the making-cylinders, as in the common construction.

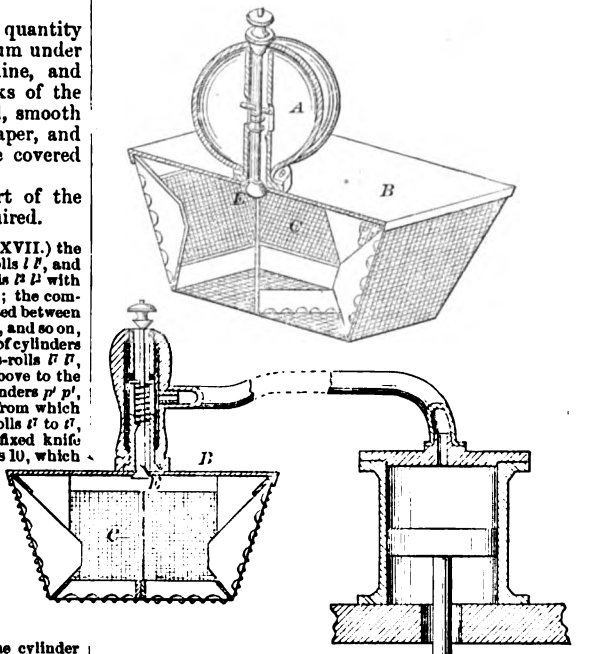
Pa'per-mold'ing Ma-chine'. One in which paper-pulp is molded to the form required, the *shape* being afterward dried. The object is then finished by sizing, varnishing, painting, or what not, according to its purpose.

Brown and Macintosh, English patent 14,131 of 1852, describes a mode of making paper and articles of paper in hollow molds or frames with permeable surfaces, and within which a partial vacuum is obtained. The mold has preferably a covering of felt, upon which the fiber is deposited while the water passes through, and this felt is removed from the *former* with its deposited paper envelope.

See also American patent of French and Frost, 1856; Brown and Smith, 1851; Hatfield, 1862.

Fig. 3533 illustrates the principle of action. A *former* of the shape required — in this case a rectangular lamp-shade — is made of wire-gauze *C* stiffened with internal strengthening plates. The figure shows a mold *B* with a hollow handle, connecting by a flexible tube with an air-pump. The pulp is collected upon the foraminous surface, through which the water passes as the air is exhausted from the interior of the *former*. The sheet of pulp is discharged by the internal pressure of air, the pump being worked as a compressor. The fiber of slightly felted pulp is received from the *former* by a felt cap which fits upon the film, and is from it transferred to a block on which it is dried.

Fig. 3533.



Knight's Paper-Molding Apparatus.

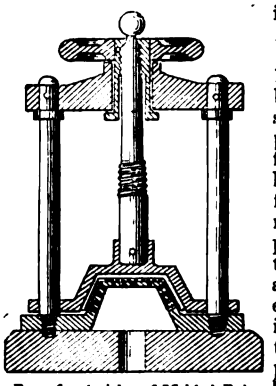
The machine just described depends upon an exhausting air-pump to draw water through the meshes of the wire-gauze which detains the fiber of the pulp, and the thickness of the film of pulp will depend upon the thickness of the pulp and the rapidity and duration of the stream of water passing the wire-gauze. The compression system, in which a quantity of pulp is driven through the meshes of a former on whose surface the fiber collects, has also been repeatedly tried. A third plan is that in which a displacing plunger descends into a molding-former and drives out the water, compacting the pulp against the sides of the *former*.

Fig. 3534 is a machine for pressing and compacting the molded article. The rigid, perforated frame, with the article formed in paper-pulp upon it, is removed and placed beneath a die which expresses the water from the pulp.

In another machine, the blanks are made from paper-pulp in shape suitable for forming boxes, etc. The creases made in the blanks facilitate the bending into form, and the notches in the corners obviate the

Digitized by Google

Fig. 3534.



Press for Articles of Molded Pulp.

necessity of cutting into shape. See also Kimball's patent, 1868.

In Smith's machine, 1868, the paper-pulp box is made by the sudden descent of a plunger into a perforated mold, which has a permanent perforated lining and removable bottom. The plunger is constructed to automatically admit air beneath its lower end just previous to its withdrawal from the cavity of the completed box or other hollow article. The bottom drops to discharge the molded box.

Leclère's machine, December 8, 1868, is designed for the formation of hollow paper articles from paper-pulp, and operates by employing over a pervious former a column of thin pulp, which in hight several times exceeds the hight of the article to be made.

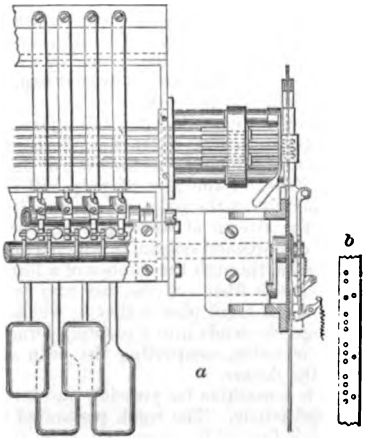
The pulp is condensed on the former and the water expelled therefrom against the atmospheric pressure by covering the pulp-covered *former* with a close vessel, and admitting air under pressure within the *former*. The paper is removed from the cap which received it from the former, and transferred to a receiving block by covering the block with the cap and admitting an air-blast into the latter.

Pa'per-mus'lin. (*Fabric.*) Glazed muslin used for linings, etc.

Pa'per-per'fo-rat'ing Ma-chine'. 1. A machine for perforating paper, as with postage-stamps in sheets, to make a weak line which may enable them to be separated by tearing.

2. (*Telegraphy.*) A machine to perforate strips of paper according to a code, the holes allowing the circuit to be closed, so that the circuit may be made

Fig. 3535.



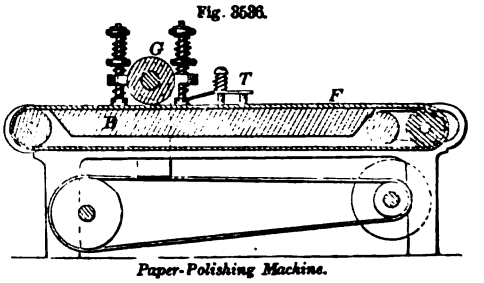
Eddison's Perforating-Machine.

and broken in a given sequence to indicate characters. Eddison's machine for this purpose is shown at Fig. 3535. *a* is the machine; *b*, a portion of a strip perforated for the use of an automatic telegraphing apparatus. A range of finger-keys is provided, and also a range of slide-plates operating upon punches. A presser-lever is connected by a cam with each finger-key, and contiguous thereto are projections upon such of the slide-plates as are to be actuated by the said finger-key; thereby, on striking the finger-key, the proper punches are actuated to punch the perforations necessary for the message complete; and on releasing the finger-key, the paper is drawn along the proper distance by a peculiar feeding mechanism, and the perforations are made in two lines, so that where three or more perforations are placed triangularly, a long pulsation may result from the metallic connection being made through these perforations successively, the contact being made through the second perforation before ceasing through the first, and so on. See also Little's patents, Nos. 91,240, 91,241.

Pa'per-pol'ish-ing Ma-chine'. A machine for surfacing paper by a burnishing action. A fine surface is given to paper by calendering and by pressure between glazed boards or hot plates. See CALENDERING.

In Fig. 3536, the paper is carried on an endless belt *F* of rubber, velvet, or other material, passing over the table *B*. The

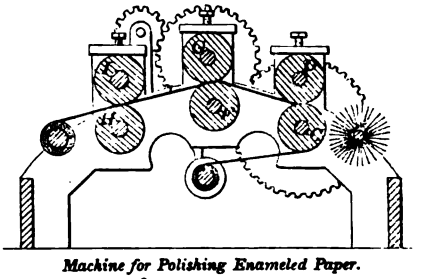
Fig. 3536.



Paper-Polishing Machine.

burnishing-roller *G* rotates in the same direction with the endless belt, but with greater velocity, or it may turn in an

Fig. 3537.



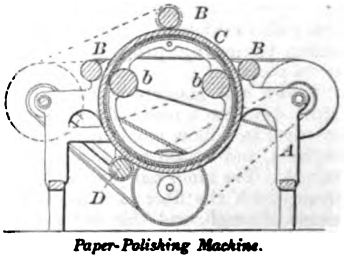
Machine for Polishing Enameled Paper.

opposite direction; it has also an endwise reciprocating movement. A spring presser-plate *T* keeps the paper down to the endless belt, and it or the table is made elastic.

Fig. 3537. The paper passes successively between the rollers *D C F G H I*.

The burnishing-rollers *G I* rotate faster than their fellows *F H*, and *I* has a greater velocity than *G*, so as to exercise a drawing action on the paper.

Fig. 3538.



Paper-Polishing Machine.

Digitized by Google

Fig. 3538. The hollow annular bed *C* is supported on rollers *b b* within its circumference, and has a reducing roll *D* revolving in contact with it to keep its periphery in true form. The paper is polished by passing between the rolls *B B B* and the hollow cylinder.

Pa'per-punch. An implement for making holes in papers for the purposes of filing, temporary binding, for the reception of eyelets, or for canceling. It is similar to the punches described under the titles of *ticket*, *conductors'*, *spring*, *leather* punches, etc.

Pa'per-rul'ing Ma-chine'. See RULING-MACHINE.

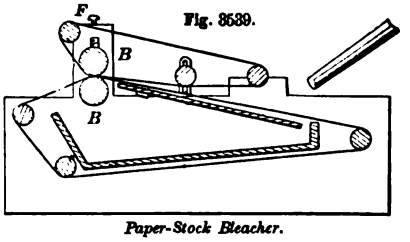
Pa'per-size. Writing-papers are sized with gelatine prepared from tanners', curriers', and parchment-makers' clippings. Plate-paper, when intended to receive impressions in colors, is sized with a clear solution of isinglass. These, or other gelatinous substances, as they impair the tenacity of the semifluid pulp, are applied subsequently to the formation of the paper into sheets or into a continuous roll. For printing papers, a compound of alum and rosin dissolved in a solution of soda and combined with potato-starch is generally used; this is mixed with the paper in the state of pulp.

Starch is also used, either in the form of a paste or as a clear solution.

Pa'per-split'ting. Two pieces of muslin are firmly cemented on the sides of the paper and dried. By a pull on each piece the paper is split open, a portion adhering to each piece of muslin. The halves are then loosened from the fabric by damping.

Pa'per-stock Bleach'er. The machine (Fig. 3539) is intended for expressing the bleaching material from paper-stock, without having recourse to the draining-vat.

Fig. 3539.



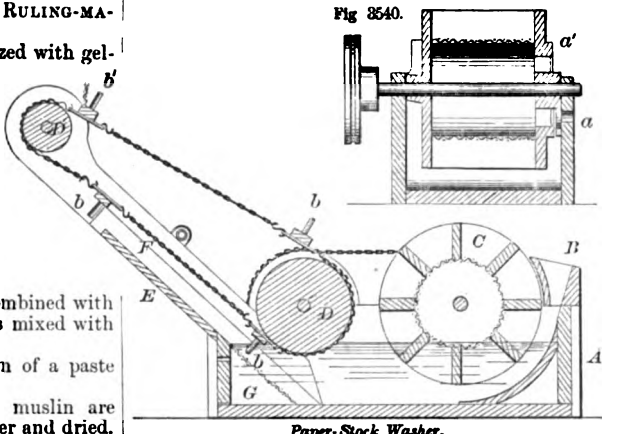
Paper-Stock Bleacher.

The stuff is delivered by a spout upon an endless apron, which is moved and kept tense by a series of revolving rollers, and passes between two rubber-covered rollers *B B*, adjustable to any desired pressure by screws *F*, which squeeze out the bleaching solution.

Pa'per-stock Wash'er. A machine for cleansing shredded rags preparatory to pulping.

The rags are fed into the hopper *B* and are drawn into the tank *A* and agitated by the arms of the wheel *C*. The axis of this wheel is surrounded by a wire-gauze drum, which permits the escape of the dirty water through the annular channel *a'* in the end of the wheel *C* and aperture *a* in the tank, through which a current of water is continually flowing; the cleansed stuff is carried up the incline *E* and delivered at any required point by means of rakes *b b b b* attached to an endless chain *F*, passing around rollers *D D'*. The rake teeth are so long that they press with some force against the incline *E*, so that when released therefrom they straighten out with considerable energy,

Fig 3540.



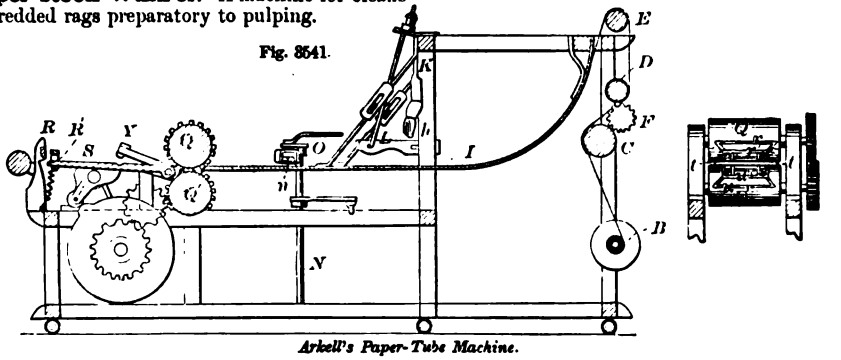
Paper-Stock Washer.

throwing off the stuff. A screen *G* separates gravel or other large particles accidentally intermixed.

Pa'per-tube Ma-chine'. Fig. 3541 illustrates a machine for forming paper-tubes, which are severed into lengths suited for making bags, the bottoms being formed at a subsequent operation.

A continuous roll of paper is wound upon the flanged cylinder *B*, and is thence drawn upwardly on the roll *C*, passing between the furrowed roller *F*, which is partially immersed in a trough containing paste or mucilage, and the rubber-covered roller *D*, by which its edge is pasted; it thence passes over the guide-roller *E*, and is conducted downward along the curved plate *I*, which is concave on its upper side, the concavity gradually increasing as it approaches the blades *L*, one on each side; two pressure-rollers *h*, suspended from adjustable bars *K*, serve to hold up the edges of the strip until it is acted on by the blades *L*, which fold the edges over, the folding process being completed by a second pair of blades *n*, attached to adjustable arms *O*. It next passes between the rollers *Q Q'* geared together at one end, the upper one of which has a series of grooves *r r* corresponding to projections *u u* on the lower, which form creases in the tube, while at the same time incisions are made by the cutters *t t* at each side; the pasted edges are thus attached and the bottom shaped. The tube next passes over a loop or guide *Y* attached to pivoted arms by which the tension is regulated as it is presented to the action of the cutters *R R'*: one of these (*R*) is stationary and the other (*R'*) attached to a plate *S*, vibrated by means of a rock-shaft; between the two the tube is cut at the proper points into lengths suitable to form the bag. See also PAPER-BAG MACHINE.

Fig. 3541.



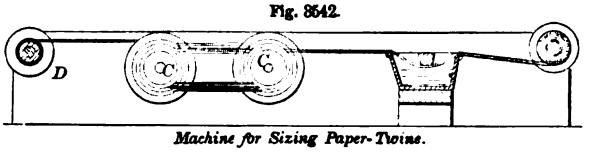
Arkell's Paper-Tube Machine.

Digitized by Google

Pa'per-twine. A kind of wrapping-twine prepared by twisting a long, continuous strip of paper.

In De Guinon's paper-twine machine, the strip is wound around a central spindle in a shallow circular pan revolving on journals, one of which is hollow and receives a tube through which the strip is drawn, being twisted at the same time by the revolution of the pan.

Fig. 3542.



Machine for Sizing Paper-Twine.

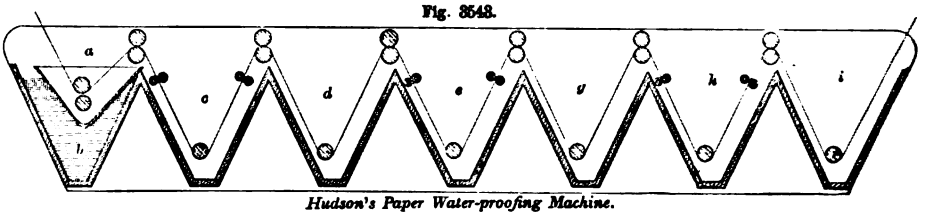
The twine is sometimes sized or varnished. This is effected by drawing it through a pan containing the sizing material. In the machine (Fig. 3542) it is at the same time caused to pass over cone-pulleys *C C*, gradually approaching their larger ends, so as to stretch it, and is then wound upon a reel *D*.

Pa'per Wa'ter-proofing Machine'. A machine for impregnating or surfacing paper with a water-resisting material.

Hudson's process of water-proofing paper passes it through a number of troughs containing chemical agents, by which it is acted upon successively.

Fig. 3543 shows a series of tanks used for this purpose. *a* contains a solution of sulphuric acid and water. To maintain this at a proper temperature, — about 60°, — a tank of ice *b* is placed underneath.

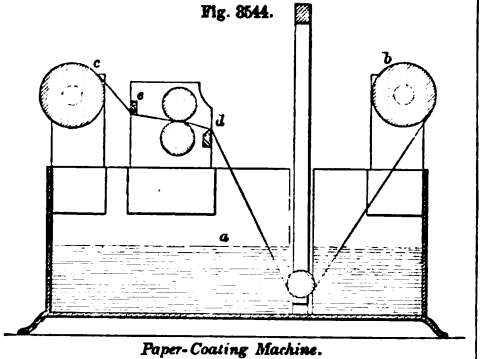
Fig. 3543.



Hudson's Paper Water-proofing Machine.

From the tank *a* the roll of paper is fed over a cylinder, passes between a pair of pressing-rollers, and down into tank *c*, filled with clear water. It then goes over another roller, and down into tank *d*, filled with dilute ammonia. It then passes over another roller, is again pressed, and goes through the vat of water *e*, where it is again washed. *g* contains lime-water, and after the roll of paper has passed through this, and been again washed in *h*, it is finally treated with glycerine in the vat *i*.

Fig. 3544.



Paper-Coating Machine.

A machine for coating paper with tar or asphaltum is shown in Fig. 3544.

a is a tar vat. *b* is a roll of paper, which is fed down into the tar, and is drawn out over the scrapers *d e*, and is wound upon the roll *c*

Pa'per-weight. Paper-weights are made of various materials, as metal, ornamental stone, or glass. The former two are made by casting or cutting, but the latter, the most beautiful objects of their kind, are formed by arranging a series of small glass tubes of different colors so as to constitute the desired pattern within cavities in a thick disk; a layer of transparent molten glass is then applied, to which they adhere so as to be removable from the disk, after which a second layer of molten glass is applied to the opposite side; the whole is then heated and shaped by means of a moistened wooden concave spatula, and is afterward annealed and polished on the wheel. Figures or portraits made from refractory clay are inclosed in a similar way; but metallic objects, which would be injured by extreme heat, are merely inserted in a properly shaped cavity previously formed in the weight and secured by a cloth glued to its lower surface. See MILLEFIORE-GLASS. See also list under GLASS.

Pa'pier-maché. A material composed principally of paper, to which other substances may be added to impart special qualities.

The art was probably derived from China. Paper-pulp was combined with gum or China clay by Montin, a German snuff-box maker, who is said to have learned the art from Lefèvre about 1740. In 1745, the year fatal to Lochiel, it was introduced into Birmingham, England.

The commoner varieties are prepared by pulping any kind or mixture of different kinds of paper into a homogeneous mass of a doughy consistence. Some earthy material may be mixed with the pulp, as well as chemicals, resinous substances, and glue to harden it and to prevent the attacks of insects. The pulp is rolled into thick sheets, and a sufficient quantity is taken to form the article of ornament desired; this is subjected to heavy pressure between cameo and intaglio dies and afterward dried. Its surface may now be gilt, painted with oil or size colors or varnished. The toughness and lightness of this material peculiarly adapt it for table-ware, table and desk furniture, interior architectural and other ornaments.

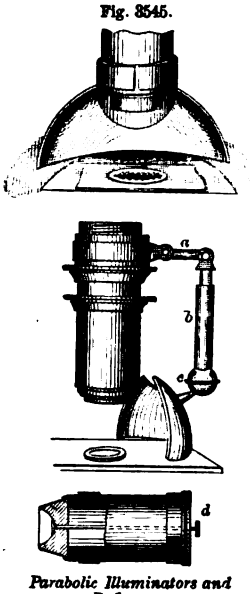
The papier-maché used for tea-trays and similar thin articles, which was introduced during the last century, and now forms an important department of industry, is made from sound whole sheets of paper of particular quality, somewhat resembling blotting-paper. These are pasted in successive layers, usually three, upon a metallic mold or pattern, and then dried, the exterior filed to give it a smooth surface, and another layer of three thicknesses applied by pasting; the whole is then again dried, three more sheets pasted on, and the alternate drying and pasting processes thus continued until the required thickness, usually 30 to 40 sheets, is attained. In some cases as many as 120 thicknesses

Digitized by Google

of paper are employed. The article is now removed from the mold by inserting a knife under its edges, and its surfaces smoothed by the plane, the file, and the knife, after which it is colored and decorated. For this purpose, several coats of shellac-varnish are applied. Japan varnish is used for finishing the surface. This is generally highly polished, the very highest polish, it is said, being imparted by the friction of the hands of women. The final decorations in paint or gilding are in the commoner class of work laid on by stenciling, but in that of the finest quality the artist's brush or pencil is used, with inlaying of mother-of-pearl.

Par-a-bol'ic Il-lu'mi-na'tor. A reflector placed over an object beneath a microscope. Its shape is that of a half-paraboloid, the object being in the focus. The interior is silvered.

Fig. 3545.



Parabolic Illuminators and Reflectors.

Fig. 3545 shows Beck's illuminator with Couch's adaptor, *a b*; this is jointed to admit of free vertical movement, and its lower branch is sleeved so that it may be turned by the thumb-screw *c* to focus the reflector on the object. It is intended especially to illuminate opaque objects.

d is a *parabolic reflector.*

Par-a-bol'ic Reflect'or. A cone of glass (*d*, Fig. 3545) with a paraboloidal depression which concentrates the illuminating rays upon an object placed in the focus. A small disk mounted on an axial pin forms a dark background behind the semi-translucent object, which is illuminated by an annular pencil of rays passing around the edge of the disk. See SPOT-LENS.

Par'a-cen-te'ri-um. (*Surgical.*) A small trocar for puncturing a dropsical eye.

Par-a-chute'. A device by which a descent is made from a balloon or eminence. It is a light structure, and affords a large area of resistance to the atmosphere.

Loubère, in his account of Siam published 200 years since, describes a machine of this kind used in descending hights.

It was not employed in Europe till 1783, when M. le Normand proved its efficacy by letting himself from the windows of a lofty house in the city of Lyons.

Blanchard, in a balloon ascension in August, 1785, let down a dog from a great hight by means of a parachute, without injury. He afterward applied it to descending from a balloon, in 1793, but, the machine failing to expand fully, he broke his leg in alighting.

The first successful descent by a parachute from a balloon was by Mons. Garnerin, in Paris, October 21, 1797; he descended again September 21, 1802, when on a visit to England for the purpose of practicing aërostation among the islanders. This parachute consisted of thirty-two gores of white canvas, formed like an umbrella of 23 feet diameter; at the top was a round disk of wood, 10 inches in breadth, having a hole in its center to admit short pieces of tape to fasten it to the gores of the canvas. About 4½ feet below the top was a hoop 8 feet in diameter, attached by a string to each seam, and below the hoop the wicker-work car was suspended.

On this occasion, owing to one of the stays giving way, the parachute was caused to "wobble" during its descent, so as to assume a nearly horizontal position at times, and the aëronaut was thrown on his face and injured.

On the 24th of July, 1837, Mr. Cocking ascended in a parachute attached to Mr. Green's balloon for the purpose of making a descent in a machine of his own contriving. It was the reverse of Garnerin's, presenting its convexity downward, like an umbrella reversed, and was no improvement upon the Frenchman's machine. He thought that it would not be subject to the fearful swaying incident to the umbrella form, but would cleave its way directly, and so it did. He miscalculated the amount of resistance, also, and provided his car with a large quantity of ballast. When he detached his parachute, the balloon of Mr. Green ascended at a fearful rate, endangering the fabric; the gas poured down on Green, and might have suffocated him but for the precaution he had taken of having some bags of atmospheric air to support respiration.

Poor Mr. Cocking shot downward, his framework expanded at a bang, breaking some of the cords, which gave it unequal areas of resistance on the respective sides. This made it sway fearfully until some more cords broke, when down he went and was killed upon the spot.

The writer will hazard the prediction that the true form of the parachute will be found in a structure resembling the thistle-seed; a multitude of parts, each light and relatively weak, but opposing an extended and pliable surface to the atmosphere, the resistance of the parachute being the sum of the multitudinous resistances of the gauzy or fibrous portions. The present type seems to be the umbrella, or the pair of wings, — one, subject to destruction if a portion give way; the other, requiring skill in direction and change with varying circumstances and currents of air.

Par-a-chute'-light. A suspended light for use in war to illuminate an enemy's position.

It consists of a large muslin parachute packed in an iron hemisphere, and attached to a second hemisphere containing a light composition. The hemispheres are soldered together. The ball is fired at a high elevation from a mortar, and when the time-fuse explodes the hemispheres are separated, the composition lighted, the parachute expanded, and the light floats along, gradually descending, the flame issuing in a jet below.

Par-a-chute'-light Ball. A combustible ball projected from a mortar to discover an enemy. The heated, evolved gases impinge upon the under surface of the parachute and keep it suspended in the air.

Par'a-close. (*Architecture.*) A screen separating a chapel from the body of a church.

Par'a-dos. (*Fortification.*) A traverse covering the interior of a work from reverse fire.

Par'af-fine. A solid hydrocarbon, crystalline and white at ordinary atmospheric temperatures, discovered by Reichenback, in 1829, in the tar derived from the dry distillation of beechwood. It has since been obtained in large quantities from coal, from bituminous shale, and especially from petroleum, by distillation and rectification by treatment with solution of caustic soda, and subsequently with sulphu-

Digitized by Google

ric acid. Several oily products analogous in composition but differing in appearance result from these processes, and are used for illuminating or lubricating purposes. The solid paraffine is derived from the densest of these oils; the paraffine crystallizing on standing a length of time. It is farther purified by the centrifugal machine and by treatment under pressure with a small percentage of sulphuric acid. Solid paraffine is employed, either alone or in combination with the fatty acids, for making candles. Its cognate hydrocarbon oils, the various derivatives from petroleum, are well known and largely employed for illumination, etc.

The name is from *parum affinis*, on account of the few substances for which it has an affinity.

The stronger acids, as nitric, sulphuric, or hydrofluoric, the former of which act energetically upon most of the metals and the latter upon glass, exert no destructive action upon paraffine; nor does aqua regia, a mixture of hydrochloric and sulphuric acids, by which gold is readily dissolved. It equally resists the action of alkalies, such as potash and soda, and is therefore adapted and used for the purpose of making joints which shall be impervious to acids and alkalies; for bottle-stoppers, which may be made of solid paraffine, or may consist of corks covered with it; and as a coating for labels and for surfaces exposed to acids or acid fumes. For this purpose it may be simply melted and applied with a brush. It may also be applied in a similar way to paper showbills, etc.; permeating the pores of the paper, it renders it water-proof, and efficiently protects it against the effects of rain.

The process of obtaining paraffine on a large scale from coal or bituminous shale was discovered and patented by James Young about 1850. That employed in the works of Mr. Young at Bathgate and Addiewell, Scotland, is briefly as follows: The shale is broken small in a crusher and then placed in the retorts; these are commonly flattened cylinders of cast-iron, about 12 feet long and contracted toward the ends, which are open, the lower one dipping in a pan of water; heat is applied by a furnace until the middle part of the retort is at a red heat; at a temperature of 300° the hydrocarbons are disengaged in the form of gas, most of which is condensible, and is collected as an oil, which is again distilled and agitated with sulphuric acid in closed vessels, where a black tarry substance resulting from the combination of the acid with the impurities of the oil subsides to the bottom. The clear portion is similarly treated with caustic soda, and again distilled in combination with vitriol and soda, the result being a thin, light, and colorless liquid known as paraffine oil.

Solid paraffine is obtained from the heavier and thicker oil, of which about 20 gallons are derived from each 100 of the crude oil; this is refrigerated by a machine in which a stream of brine is cooled below 32° by a cold-air blast, when the paraffine assumes the solid form.

Par'a-gon. (*Printing.*) A size of type between Great Primer and Double Pica.

Par'a-gran'di-ne. An instrument to avert occurrence of hail-storms. See PARAGRELE.

Par'a-graph. A reference-mark (¶). Also used to indicate a new subject.

Par-a-grele'. A small lightning-conductor set up by means of a pole in French vineyards to aid in drawing off the electricity from the atmosphere over them. The intention is to prevent the occurrence of hail-storms. Arago proposed that the conductors should be raised and supported by small balloons connected by slender wires or chains with the ground. *Paragrandine.*

Par'al-lel. 1. (*Fortification.*) A wide trench parallel to the attacked work, for protecting the besieging troops. The parallels connect the approaches or zigzags by which advances are made on besieged works.

2. (*Printing.*) A reference-mark (‖).

Par'al-lel Bar. (*Steam.*) A rod in the side-lever engine, forming a connection with the pump-rods and studs along the center line of the levers.

Par'al-lel File. One which has no taper, but preserves its size from tang to point.

One which is flat and strictly correct is known as a *dead-parallel* file.

A round file without taper is a *joint-file;* used for filing the apertures in snuff and musical boxes, hinges, etc., for the reception of *joint-wire.*

Par'al-lel Knife. Two knife-blades in one handle, set *parallel* to each other, with one or more

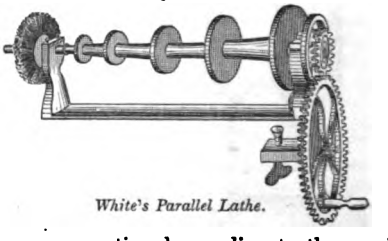
Fig. 3546.

Parallel Knife.

screws to regulate their distance. Used for cutting thin sections for microscopic examination. A *Valentine knife* or *double knife.*

Par'al-lel Lathe. A small bench-tool for dentists', jewelers', and watchmakers' uses. As shown, it is capable of running five corundum stones, a brush, and a drill at the same time. It has a cast-iron frame, with steel spindle and axles, and weighs about eight pounds. It is adjusted to the table or work-bench by a screw-clamp. The collars that retain the grindstones are made of wood, and the

Fig. 3547.



White's Parallel Lathe.

lengths are proportioned according to the requirements of the operator.

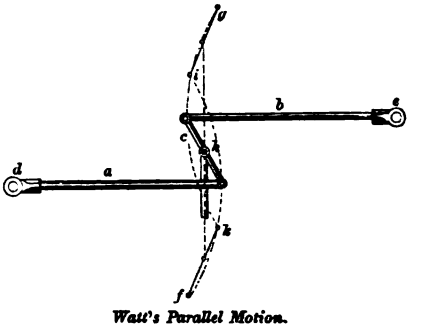
Par'al-lel Mo'tion. (*Steam-engine.*) The device and its name are the invention of James Watt. It is designed to connect the piston and pump rods with the working-beam in such a manner that the former shall move in straight lines.

The principle of the mechanism consists in the fact that in every parallelogram three angles being attached and revolving in arcs of circles, the fourth will continue nearly in a straight line of movement.

Fig. 3548 illustrates Watt's parallel motion.

The equal rods *a b*, connected by the link *c*, are pivoted at *d* and *e*; the piston-rod is connected to the middle point of the rod *c*. During the upward and downward movements of the

Fig. 3548.



Watt's Parallel Motion.

piston, the free ends of the rods *a b* are caused to vibrate in the arcs *f g*, *i k*; one end of the rod *c* being drawn to the left and the other end an equal distance to the right, compelling its middle

Digitized by Google

point *h*, to which the piston-rod is attached, to reciprocate in a line which does not vary sensibly from a straight one, and which may for all practical purposes be considered such.

Fig. 3549 shows various other devices for causing parallel motion. *A* was used in Watt's original single-acting beam-engines; the piston-rod has a rack gearing with a toothed segment on the beam and working against a roller.

B is commonly used in stationary beam-engines.

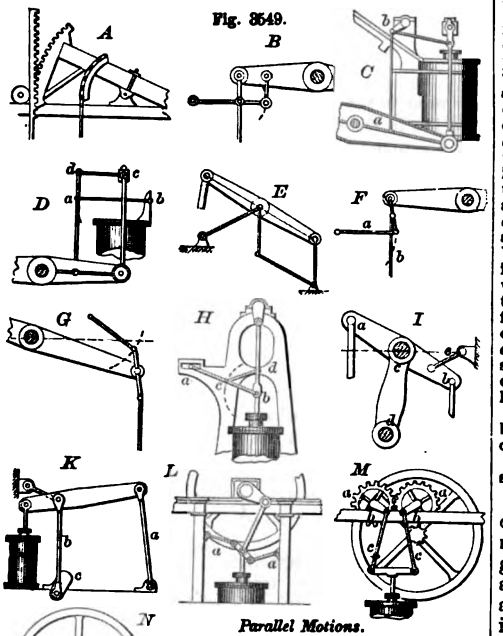
C is used for side-lever marine-engines; the parallel rods from the beam or side-lever *a* are connected with an arm on a rock-shaft *b*.

D, another parallel motion for side-lever engines; *a b* is the radius bar, and *c* the cross-head to which the parallel bar *c d* is attached.

E is used only in some particular cases.

F, the radius rod *a* is connected to the lower end of a short vibrating rod, the upper end of which is connected with the

Fig. 3549.



Parallel Motions.

beam and its center with the piston-rod *b*.

G, a modification of the foregoing in which the radius bar is placed above the beam.

H, one end of the bar *a b* is connected with the piston-rod and the other slides in a slot; the radius bar is pivoted to this bar and the piston-rod, at *c* and *d*.

I, the beam *a b* is pivoted on a vibrating standard *c d*; the radius bar *e* produces the parallel motion.

K, "grasshopper" beam-engine; *a* is a rock-shaft supporting one end of the beam; the shaft *b* is placed as near the cylinder as the crank *c* will work, and in conjunction with the radius bar *d* causes the beam to reciprocate in a vertical line.

L, used in upright engines; *a a* are radius rods connected at one end with the framing and at the other with a vibrating piece at top of the piston-rod.

M, invented by Dr. Cartwright in 1787: the wheels *a a* have equal diameters and numbers of teeth; the cranks *b b* are of equal radius and are set in opposite directions, keeping the connecting rods *c c* attached to the cross-head of the piston-rod at equal obliquities during its upward and downward movement and causing the piston-rod to move in a straight line.

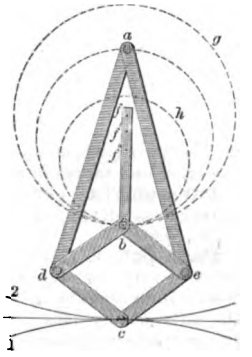
N, the piston-rod *a* is connected with a wrist on the cog-wheel *b*, which turns on a crank pin carried by a plate *c*, which is fast on the shaft; the wheel *b* revolves within a stationary internally toothed gear *d*, of double its diameter, giving motion to the crank-pin, by which means the piston-rod is kept upright.

A very original arrangement for causing a mathematically perfect parallel motion was invented in France, about ten years ago, by M. Peaucellier, an officer of engineers, but has only recently attracted the attention which its importance seems to demand. Professor Sylvester, who first brought it into notice in England, says:—

"It will give to the mechanician unlimited command over the means of transforming motion, and is an instrument that amounts to a new vital element of machinery; perhaps the most important addition to it since Archimedes's invention of the screw, about 250 [236] years B. C.; one that raises the theory of link-work to the dignity of a calculus, that enables the algebraist to fashion and write out in his study, by the rules of his science, a working plan for compelling a system to perform some of the most complicated movements that can be required for any purposes of the useful arts in their most refined and varied applications."

It consists of six pieces, *a d*, *a e*, *b d*, *b e*, *d c*, *e c*, jointed together, as shown in Fig. 3550.

Fig 3550.



Peaucellier's Parallel Motion.

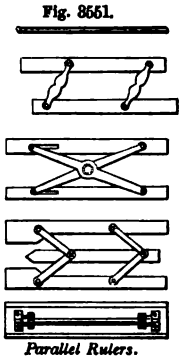
At *a* is the fulcrum on which the apparatus turns. *b* is the point at which power is applied, and *c* the point at which it acts. At *b* a rod *b f* is attached to the rhomb *d b e c*, and this may be pivoted at any portion of its length; if pivoted at a point *f*, less than half-way between *a* and *b*, and power be applied at the point *b*, this will describe an arc of the circle *g*, exterior to *a*, while the point *c* will follow a curve 1 convex toward *a*; on the other hand, if the pivoted point be at *f'*, the point *b* will move in an arc of the circle *h* interior to *a*, and the point *c* will describe a curve 2 concave toward *a*. When, however, the arm *f b* is pivoted at a point *f'*, midway between *a* and *b*, the arc traversed by *b* will of course form part of a circle whose circumference passes through *a*, while the point *c* will move, not in a line approximately straight, as the head of the piston-rod does under the operation of the parallel motion of Watt, but in a mathematically straight line.

By varying the position of the pivotal point the point *c* may be caused to describe an infinite number of curves either concave or convex toward *a*.

By an amplification of the parts other curves may be described, as parabolas, hyperbolas, and other conic sections.

Par'al-lel Rul'er. A draftsman's instrument, consisting of two wooden or metallic blades, so joined together by jointed cross-pieces as to open to different intervals and yet retain their parallelism.

Fig. 3551.



Parallel Rulers.

A still simpler form is a rolling cylinder *a*.

b is the ordinary form of two-leafed ruler with two links.

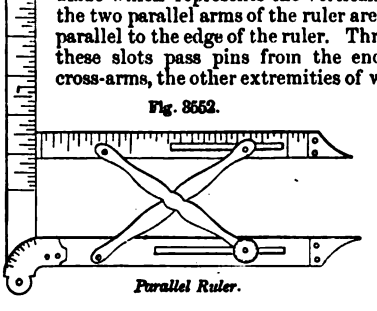
c is a two-leafed ruler with cross links.

d is a three-leafed ruler, the middle section being united by links to the main sections.

e is a flat ruler with a pair of grooved wheels, fixed on an axis, rotating in bearing-posts fastened to the ruler.

Fig. 3552 is a form of ruler having a graduated ruling-blade moving in contact with a graduated blade which represents the vertical. In the two parallel arms of the ruler are slots parallel to the edge of the ruler. Through these slots pass pins from the ends of cross-arms, the other extremities of which

Fig. 3552.



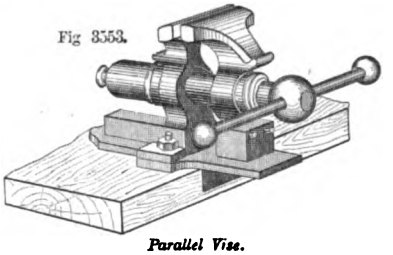
Parallel Ruler.

Digitized by Google

are pivoted to the two parts of the ruler; distances apart of the bars are measured on the vertical bar.

Par'al-lel Vise. A vise whose jaws move in exact parallelism, a bar on one slipping in a socket in the other; in contradistinction to the kind in

Fig 3553.



Parallel Vise.

which the shank of one jaw is pivoted to that of the other and moves in an arc of a circle.

Par'a-mat'ta. (*Fabric.*) A light twilled goods having a cotton warp and a merino-wool weft. *Paramatta cloth.*

Par'a-pet. 1. (*Fortification.*) A breast-high defense of earth or stone around a work for shielding troops from the enemy's fire. It is so formed that the earth of the excavation (*deblai*) is sufficient for the ramparts and parapets (*remblai*). Inside is the body of the place; outside are the ditch, glacis, etc.

9. fraise.
10. scarp or revetment.
11. ditch.
12. counterscarp.
13. covered way.
14. banquette of the glacis.
15. glacis.
16. abattis.

2. (*Architecture.*) A wall carried up on the brink of a quay, bridge, or house-top.

Par'a-sol. A sunshade, usually smaller than the *parapline* or umbrella (which see).

Parasols and feather fans, large enough for sunshades were carried by attendants, and are shown in the ruins of Egypt, Persepolis, Nimroud (*Nineveh*).

Sylax, an ancient historian, asserted that there dwelt in India countrymen with feet of so large a size that they used them for parasols. (Philostratus.) Herodotus rejected the *yarn*, as also the statement repeated by Strabo, that the ears of some of these Indians were like winnowing-fans, and that they wrapped themselves in them to sleep.

The Chinese invented the folding parasol or umbrella. Their modern use dates from 1820, and their present form is said to have been devised by the Duchess of Rutland. The Chinese paper-parasols, called *kittysols*, are now largely exported. The gift of a parasol is said to be a mark of kingly favor in China.

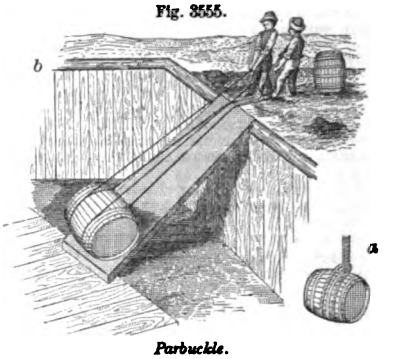
"Artaxerxes gave to Entimus, the Gortinian, a couch with silver feet, and cushions for it, and a flowered tent surmounted with a canopy, and a silver chain, and a gilt parasol, and vessels of gold and silver, and 100 girls and 100 boys," etc. — ATHENÆUS.

Par'a-ton-nerre'. (*French.*) A lightning-conductor. See LIGHTNING-ARRESTER; LIGHTNING-ROD.

Par'buck-le. A double sling *a* made of a single rope, for hoisting or lowering a cask or gun.

A means for raising or lowering (*b*). The bight of

Fig. 3555.



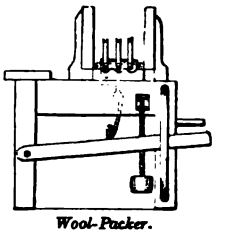
Parbuckle.

the rope is placed round a post; the cask, spar, or gun lies in the double loop.

This plan is adopted in Captain Cunningham's mode of furling sails by rolling the yard. The latter lies in the bight of the chain, and is rolled as it is raised or lowered, the yard-arms resting in hoops slung from the *lifts*.

Par'cel. (*Nautical.*) A wrapping of tarred canvas on a rope to prevent chafing. It is cut in long, narrow strips, well tarred, and made up into rolls before commencing to lay it on the rope. Usually, the rope is *wormed*, then *parceled*, and then *served*. See under those heads.

Fig. 3556.



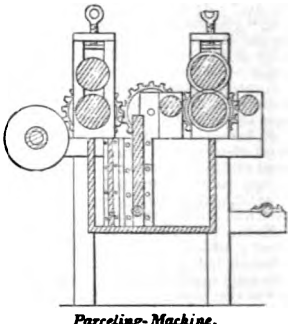
Wool-Packer.

Par'cel-ing-ma-chine'. 1. A press in which yarn, cloth, or wool, etc., is bundled up compactly for tying. See BUNDLING-PRESS, page 405; FLEECE-TYER; WOOL-PACKER, etc.

The example is a machine for bundling and tying fleeces. The fleece is laid upon the table, the slotted belt brought over it and attached to the treadle-lever, whose depression draws the belt and brings up the twine-carrying fingers through the slots in the belt and over the fleece.

2. A machine in which strips of canvas or cloth are dipped preparatory to wrapping around ropes or cables.

Fig. 3557.



Parceling-Machine.

The example is for the manufacture of parceling or tarred canvas covering for ropes, seams, etc., in vessels. The machine consists of cutting and drawing and pressure rolls, in combination with an interposed tank for the tar in which the material is immersed, and bobbins or spools upon which the prepared canvas is wound in rolls.

Parch'ment. Fine parchment is manufactured from the skins of young calves, kids, lambs; also from sheep and goat skins. Extra fine, thin parchments are made from the skins of still-born lambs, kids, and calves.

Coarse parchment for drum-heads, etc., is made

Digitized by Google

from calves', wolves', asses', and he-goat skins. The ass's skin is said to be remarkably sonorous, and it is no wonder, seeing the amount of noise it has contained at various times. The Greeks found the bones of the ass to be a superior article for making flutes. The flute and drum, a rich asinine combination, which probably suggested the bagpipe, whose drone is the nearest to the paternal blare of anything artificial.

After removing the wool, the skin is steeped in lime and then stretched in a wooden frame; its face is then scraped with a half-round knife. The next process consists in rubbing the skin, previously sprinkled with powdered chalk or slacked lime, and scraping it with a knife. It is then rubbed with a lamb-skin having the wool on, to smooth the surface and raise a very fine nap; after which, if any greasy matter remains, it is again steeped in the lime-pit for a few days. The grain surface is then removed with a knife and the skin pumiced, if necessary, to give it an equal thickness.

In coloring parchment, a green color may be given by spreading with a brush a solution made with crystallized acetate of copper, 30 parts; bitartrate of potassa, 8 parts; rain-water, 500 parts; nitric acid, 4, added when cold.

The substance is said to have been invented by Eumenes, king of Pergamus, as a substitute for papyrus, on which an embargo was laid by Ptolemy Epiphanes as Eumenes was collecting a library in emulation of the famous one in Alexandria. After the library in the Bruchion was burned, during the siege of Alexandria by Julius Cæsar, Marc Antony presented to Cleopatra the rival library of Pergamus, consisting of 200,000 volumes (*volumen*, a scroll). It was subsequently destroyed, the Saracens burning what Theodosius had left. See PAPER.

Parch'ment-pa'per. Made by immersing ordinary unsized paper in sulphuric acid, diluted with about half its volume of water. It is withdrawn in a few moments, and on drying is found to have assumed a new character, resembling rather that of animal membrane than vegetable fiber, and its strength is nearly doubled. After the immersion it is washed in water, afterward in dilute ammonia, and if any of the latter remains it is removed by lime or baryta.

It was invented and patented in England by Mr. Gaine. Figuer and Pomarede made attempts in the same direction in France, 1846.

Karchiski, in 1860, subsequently treated the paper with glycerine, to give it suppleness. Stuart Gwynne made fractional currency of it about 1865 or 1866.

To avoid the imperfect penetration of the acid, J. J. Ott treated a number of thin sheets with the acidulous solution, and combined them into a homogeneous sheet.

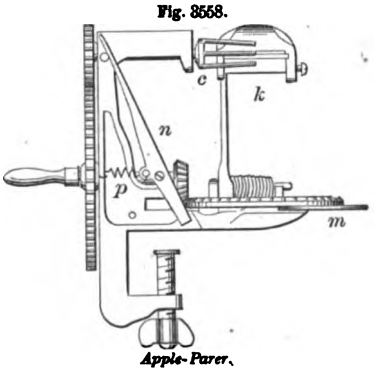
A. T. Schmidt added the glycerine to the acid.

Thomas Taylor (England, 1869; United States, 1871) treated the paper with chloride of zinc. See,—

Hudson, March 16, 1839.
Hudson, September 27, 1870, two patents.
Sheldon, January 25, 1870.
Schmidt, April 4, 1871.
Hanna, October 31, 1871.

Par'close. (*Nautical.*) The limber-hole.

Fig. 3558.

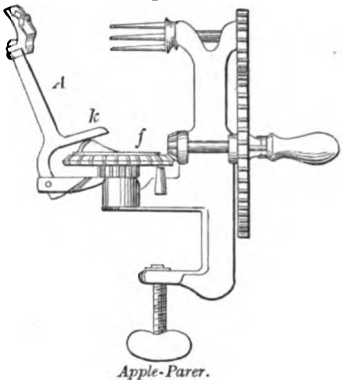


Apple-Parer.

Pa-ren'the-sis. A mark consisting of two curved lines face to face ( ). They inclose matter which is cognate to the subject, but which may be omitted without impairing the grammatical construction or the substantial meaning.

Par'er. In Fig. 3558, the apple, fixed on the rotary fork *c*, is pared by the knife *k*, also rotated by bevel gearing. When the knife makes a revolution, completing the paring operation, a projection *m* on the horizontal bevel-wheel strikes the foot of the pivoted lever *n*, throwing its upper end forward so as to push the apple from the fork. The lever is then brought back to place by a spring *p*.

Fig. 3559.



Apple-Parer.

In the apple-parer (Fig. 3559) the cutter is carried on an upright *A*, pivoted at bottom, having a projecting arm *k*, which is once during each revolution struck by an inclined cam on the upper side of the bevel-wheel *f*, causing it to make a partial revolution, and throwing the knife back so that the apple may be readily removed from the fork.

Par'get. (*Plastering.*) *a.* A plaster formed of lime, sand, hair, and cow-dung, for lining the interior of flues. *Pargeting.*

b. A plaster-work executed in raised ornamental figures, molded or impressed by the trowel.

c. A stucco.

Pa'ri-an. (*Pottery.*) A variety of porcelain having the appearance of Carrara marble, and made by the substitution of soft feldspar for Cornish stone in the porcelain process.

It derives its name from the celebrated marble of Paros, and is much employed for statuettes and other works of art.

It is composed of about $\frac{2}{3}$ silica and nearly $\frac{1}{3}$ alumina, with a small proportion of soda, potash, lime, magnesia, and iron. These are finely ground and thoroughly mixed to a creamy consistence. The fluid is poured into a mold and afterward baked. Some of the articles made by this process consist of many pieces which require to be joined together. The inequalities of the joints are then obliterated and the work baked and annealed.

Par'ing. (*Bookbinding.*) Thinning the leather toward its edge so as to prevent a square projection at its terminating edge.

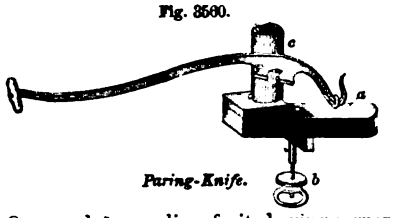
Par'ing-chis'el. A joiner's chisel having the basil on one side, used in fitting and finishing; not differing essentially from a *firmer*. Its name is derived from its being used by hand, with a paring action, in contradistinction to the *socket* and the *mortise* chisels, which are adapted for the mallet.

It is usually longer in the blade than a *firmer*-chisel and lighter than a *mortise*-chisel.

Par'ing-knife. 1. A knife used by wood-turners and others for roughing out work; it has a hook at one end passing through an eye-bolt in the block *a*, allowing considerable freedom of motion; the block is secured to a lathe or work-bench by screw attachment *b*; *c* is a piece of wood being pared.

Digitized by Google

Fig. 3560.



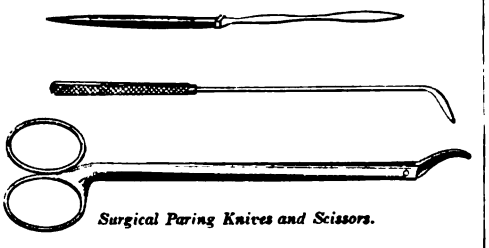
Paring-Knife.

2. One used for peeling fruit, having a guard to regulate the depth of cut.

3. A farrier's hoof-paring tool.

4. (*Surgical.*) A knife used in removing the cuticle or ragged edges of parts which are to be placed in apposition that they may grow together.

Fig. 3561.



Surgical Paring Knives and Scissors.

The examples are respectively, —

Upper one, Sim's knife for paring edges in the operation of vesico-vaginal-fistula.

Below it, curved knife for same operation and that of cleft palate.

Par'ing-ma-chine'. A key-grooving machine.

Par'ing-plow. (*Husbandry.*) A plow for cutting sods or turfs from the surface of the ground. A *sod-plow.*

Par'ing-scis'sors. (*Surgical.*) A scissors for trimming the edges of wounds, or freshening the edges of fistulous openings, in order that they may grow together when brought into apposition and secured.

Fig. 3561, lower cut, represents Dr. Emmett's double-curved scissors for paring edges in the operation of vesico-vaginal-fistula and cleft palate.

Par-is'ian Gold-col'ored Al'loy. A factitious gold. See OROIDE; also ALLOYS for jewelers, page 63.

Par-is'ian White-met'al. An alloy composed of copper, 69.8 parts; zinc, 5.5; nickel, 19.8; cadmium, 4.7. See ALLOY, page 63.

Pa-risth'mi-o-tome. (*Surgical.*) An instrument for scarifying the tonsils.

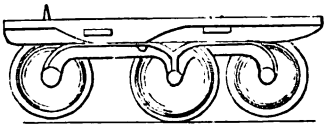
Park. A place of encampment of an artillery train.

Par'lia-ment-heel. (*Nautical.*) The position of a ship when careened.

Par-line. The mean or normal line of a barometer for a given station.

Par'lor-skate. A skate on rollers for use on a floor or carpet. (See SKATE.) In the one shown, the wheeling motion of the skater is facilitated by a middle driving-wheel which descends below a line drawn between the other two wheels.

Fig 3562.



Parlor-Skate.

Pa'ros-mar'ble. A semi-transparent white marble tinged with yellow.

Par'point-work. (*Masonry.*) Squared stones laid in *stretcher*-course and with *header*-courses at intervals of, say, 3 feet.

Par'quet-ry. An ornamental mosaic woodwork in the different colors of woods, or their different grains are so ordered as to form patterns. See also MARQUETRY; MOSAIC; BUHL; REISNER-WORK.

Par'ral. (*Nautical.*) The hoop or collar of greased rope by which a yard is shackled to the mast, at the slings, the *parral* slipping on the mast as the yard is raised or lowered.

Iron parrals are now in common use.

The parral is connected to sling-cleats on the yard, and has strung upon it *parral-trucks*, that is, small wooden globes to prevent friction or binding against the mast, in hoisting or lowering.

Par'ral-rope. (*Nautical.*) A single rope, well served, and formed into a collar around a mast for slinging an upper yard.

Par'rott-gun. (*Ordnance.*) A kind of rifled cannon invented by Captain R. G. Parrott of the Cold Spring Foundry, West Point, N. Y., and much employed in the United States service during the late civil war. The body of the gun is of cast-iron, and is reinforced at the breech by shrinking on a ring of wrought-iron.

The calibers are, 10-pounder, 2.9 inches bore; 20-pounder, 3.67 inches bore; 30-pounder, 4.2 inches bore; 100-pounder, 6.4 inches bore; 200-pounder, 8 inches bore: corresponding respectively to 3, 6, 9, 32, and 64 pounder smooth bores. The number of grooves increased with the caliber of the gun, the 10-pounder having three.

Part. (*Founding.*) A certain portion of a mold or flask; as the *top part* or *drag*, the *bottom part* or *cope*, the *middle part* contained in the middle portion of a *three-part* flask, etc. (See FLASK.) The *false part* is a flask rammed up, generally a top part turned over, stricken off, and a cavity scooped in it to receive temporarily the bulge of a pattern while sand is being rammed upon the upper surface. The whole is then turned over, the *false part* destroyed, and the *parting* made.

Part'ing. 1. (*Metallurgy.*) Separating silver from gold by an acid.

2. (*Paper.*) Separating the moist sheets.

3. (*Nautical.*) Breaking cable, leaving the anchor in the ground.

4. (*Founding.*) The meeting surfaces of the sand rammed up in the *cope* and in the *drag.*

A powder is applied to the faces to enable them to separate readily. This parting may consist of dry sand free from clay or other tenacious matter, or of brick powder.

The *facing* is a material applied to the sand where the metal will come in contact with it. See FACING.

The *parting* of loam surface. See LOAM-MOLDING, page 1461.

5. (*Comb-making.*) A mode of making combs to economize material, in which a pair of combs are made from a single slip a little over comb-width. A cutter has a vertical motion upon the blank, which has an intermittent feed beneath it, making a series of cuts, the teeth of each comb occupying the interdental spaces of the other. See COMB-MAKING.

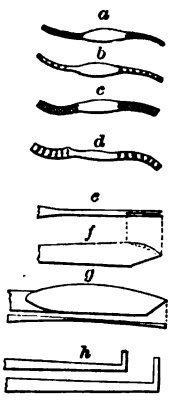
Part'ing-line. (*Founding.*) The line upon a pattern as it lies imbedded in the sand, below which the *draw* of the pattern is upward, and above which it is downward. This line in the majority of cases is undulatory, and the surface of the sand-parting extends from it to the edges of the flask all round.

Part'ing-sand. (*Founding.*) Dry sand free from clayey compounds placed between the two members of a mold to facilitate their separation.

Part'ing-tool. 1. (*Marble-working.*) A rasp

Digitized by Google

Fig. 3568.



Parting-Tools.

of peculiar shape, coarse or fine in grain, and used by marble-workers (*a b c d*, Fig. 3563).

2. (*Turning.*) A cutting-tool used by wood and ivory turners for separating turned pieces from the block, turning out interior cylinders, etc.; *e f*, parting-tool for soft wood; *g*, for hard wood; *h*, inside parting-tool for removing rings from the interior of solid works, avoiding loss of material in shavings; it is also useful in some other under-cut works.

3. (*Carving.*) An angular gouge like a hollow graver, used for marking outlines, tendrils, stems, and markings of leaves, etc.

4. (*Joinery.*) A chisel with a bent edge.

Par-ti'tion. (*Carpentry.*) A division between rooms, etc.

The scantling in a partition is as follows: —

Sill, the bottom-piece.
Head, the upper plate.
Principal posts, the main uprights.
Quarters, the intermediate studding.
Braces, oblique ties.

Part'ner. (*Nautical.*) A framework or bushing in or around a hole in a deck to receive the heel of a mast, bitt, or pump, or to form a basis for the pawls of a capstan.

The framework consists of *fore-and-aft partners*, *cross-partners*, and *corner-chocks*.

Par'ty-gold. (*Metallurgy.*) Beaten or leaf silver with a coating of gold on one side.

Par'ty-wall. (*Building.*) A wall separating two adjoining tenements. Originally, it meant a wall built upon the lands of two adjoining proprietors which furnished support for the floors and roofs of the tenements on each side. Laws regulating this right of joint occupation are in force in Europe and America. It should run above the roof.

Par'vis. An area before the entrance of a church or around it. *Parvise.*

Pas-de-sou'ris. (*Fortification.*) A staircase from the ravelin to the ditch.

Pass. (*Rolling-mill.*) *a.* The shape produced by the grooves in the adjacent rolls of a rolling-mill. The *pass* is so formed as to give the required shape to the metal rolled therethrough. The most important and frequently occurring forms are rails, tires, angle-iron, deck or T and I beams, half-round forms, such as felly-iron, etc., and some of the principal varieties of spike and sash iron. See IRON, ANGLE.

b. A single passage of a plate or bar between the rolls.

Pas-sa-ree'. (*Nautical.*) A tackle to spread the clews of a fore-sail when sailing large or before the wind.

Pass-boat. A broad, flat-bottomed boat. A *flat* or *punt*.

Pass-box. A wooden box used for conveying cartridges from the magazine to the guns in forts and batteries. It is 7 inches in depth and width by 14 inches long, having a hinged cover and a handle at one end.

Passe-par-tout'. 1. (*Engraving.*) An engraved plate or block, forming a frame around an aperture into which any engraved plate or block may be inserted.

This is common in wood-engraving, where an ornamental border may be made to do duty with changing central advertisements or labels.

It was also adopted a number of years since with the notes of the State Bank of Ohio, when such things were, the inserted blocks representing the names of the several branches.

Also understood to be adopted in the national bank-notes.

2. A frame or mat to go around a picture. Frequently a pasteboard border for a picture beneath the glass and within the frame.

Pass'ing-place. (*Railway Engineering.*) A *siding*.

Pass'key. One that will open several locks. A *master-key*.

Paste. A soft adhesive composition.

1. A mixture of flour, water, starch, etc., variously compounded in different trades, such as *bookbinders*, etc. The paste is sometimes strengthened by starch, and preserved from mold by carbolic acid.

Size is a thin glue, but many pasty compositions are called size in the trades, as in calico-printing.

2. (*Calico-printing.*) A boiled composition of flour, starch, or gum with water, used as a vehicle for *mordant*, *color*, *resist*, or *padding*, or *discharge*. Also called *thickening*.

Sieburger's adhesive paste: Four parts, by weight, of glue are soaked for several hours in 15 parts of water, and then slowly warmed until a perfectly clear solution is formed This solution is then diluted with 65 parts boiling water and thoroughly stirred. In the mean time, 30 parts of starch are stirred into 200 parts of cold water, so as to form a thin milky liquid, free from lumps. Into this is poured the solution of glue, stirring continually and heating. When cold, ten drops of carbolic acid are added. It is said to possess extraordinary adhesive power, joining leather, paper, pasteboard, etc. By keeping it in closed vessels, so that the water cannot evaporate, it may be preserved for years.

2. For attaching labels to glass or porcelain, gum tragacanth is generally employed A small quantity of corrosive sublimate will preserve it, though this is seldom necessary. A solution of shellac in borax is also useful for this purpose. Dextrine, or British gum, is generally used for rendering labels adhesive, but does not adhere firmly to glass.

3. For leather-workers alum or rosin are added to the above.

4. *Chinese* paste is a cement of bullock's blood, quicklime, and water, for stone, earthenware, or wood.

5. *Furniture* paste is beeswax and turpentine.

6. *Polishing* paste, for metals, is made of materials of varying grit and vehicle, according to the need, — rotten-stone, emery, tripoli, bath-brick, soft-soap, olive-oil, lard, turpentine, etc.

7. *Shaving* paste is a perfumed soap.

8. Dough for pastry.

9. Certain confections, such as jujube.

10. (*Pottery.*) An earthy mixture for making ceramic wares.

11. (*Glass.*) A highly refractive vitreous composition of pounded rock-crystal melted with alkaline salts and colored with metallic oxides. Used for making factitious gems.

The kind known as *Strass*, from its inventor, is a highly refractive and pellucid glass. It contains a large quantity of oxide of lead, and frequently of borate of lead.

The art was known to the ancients, some specimens having been found in the Egyptian tombs. This wonderful nation also were possessed of the art of engraving gems. Among the Jews who made their exodus from Egypt was Bezaleel, of the tribe of Judah, who was able to cut, engrave, and set precious stones, to make the stones of the breastplate like "the engravings of a signet," each one with the name of one of the twelve tribes.

The art of making paste for gems was lost for many centuries, but was revived near the end of the fifteenth century by a Milanese.

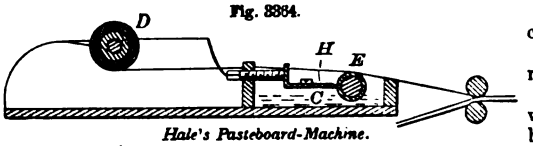
12. Gypsum in water for plasterers.

Paste'board. A thick paper board, made by pasting together a number of sheets of paper. This is afterward pressed to remove the water of the paste, dried and calendered. See also CARDBOARD.

In Hale's machine for lining straw-board or thick paper with a thinner material, the thin lining-paper is wound on a roll *D*, and is caused to pass over a

Digitized by Google

Fig. 3564.

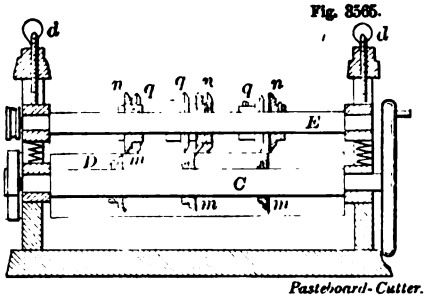


Hale's Pasteboard-Machine.

pasting-roller *E* in the trough *C*, provided with an adjustable knife or scraper *H*. The thick board is fed up from below and united to the lining by a pair of rolls, between which the two conjointly pass.

Paste'board-cut'ter. The machine (Fig. 3565) is for grooving and cutting pasteboard strips employed for making boxes. The board passes successively between the rollers *D F*, *C E*. The rollers *F* are provided with grooving disks *q*, which are opposed to the surface of the plain roller *D*, and may be adjusted to crease the board at any desired distance from the edges severed by the circular cutters *n n*; the roller *E* may be raised or lowered by screws *d d*, to cause more or less overlapping of the cutters *m n*.

Fig. 3565.



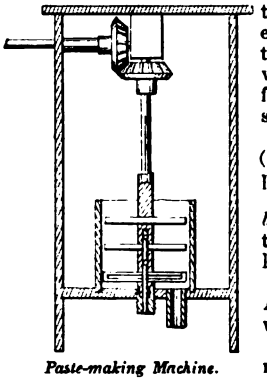
Pasteboard-Cutter.

Pas'tel. 1. A solid colored pencil made of fine pipe-clay, gum-water, and the required pigment. The executed work is called a drawing in chalk colors. It requires the protection of glass.

2. (*Dyeing.*) Woad. It gives its name to the vat in which pastel and indigo are used, the *pastel-vat*.

Paste-mak'er. A stirring-machine for mixing the components of paste. The vertical shaft is tubular at the lower end, and receives steam through its step-block, which is screw-threaded for coupling to the steam-pipe.

Fig. 3566.



Paste-making Machine.

Paste-points. (*Printing.*) Register-points on a tympan.

Paste-pot. (*Book-binding.*) A vessel containing paste, which is laid on with a brush.

Pas'tern. (*Menage.*) A shackle for horses while pasturing.

Pas-tille'. An aromatic paste for burning as a fumigator or disinfectant. It is composed of gum benzoin, sandal-wood, spices, charcoal-powder, etc.

Pat'a-mom'e-ter. An instrument for measuring the force of currents.

Patch. 1. A greased piece of cloth wrapped around a rifle bullet.

2. A reinforce or strengthening piece on a fabric at a point of wear, or around a hole or eyelet.

3. An additional or substitute piece in the covering or sheathing of a structure.

4. A binding or clamp on an emergency for a ruptured hose.

5. A block on the muzzle of a gun to do away with the effect of dispart; making the line of bore and line of sight parallel.

Pa-tel'la-ap'pa-ra'tus. (*Surgical.*) An apparatus for treating fractures of the kneepan. It consists of two curved plates of sheet-iron connected by two side rods and a back rod *a*, having attached a double reversed screw with a key *b*, by turning which the two projections *c d* are caused to approach or recede from each other. Two buckling straps are attached to each plate; these are applied to the lower part of the thigh and calf of the leg. The fractured parts are coapted, and strips of adhesive plaster *e f* applied above and below the kneepan; these are tightened by turning the key *b*, keeping the parts of the kneepan together.

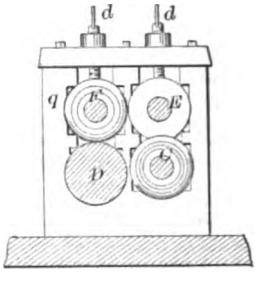


Fig. 3567.

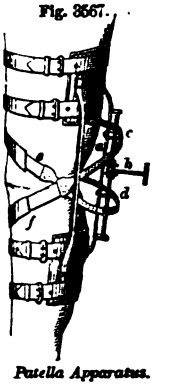


Patella Apparatus.

Pat'en. The plate which holds the wafer or consecrated bread of the communion service. It is sometimes made to fit the *chalice* or cup.

Pat'ent Leath'er. A varnished or lacquered leather used for boots and shoes and in carriage and harness work. It embraces a number of varieties and qualities. Black is the usual color, but it is also made of red, green, blue, and other tints.

The leather is specially prepared for the purpose, and is usually hemlock tanned; it is highly limed and treated with weak sour liquor, undergoing but a light *stuffing*. The hides are then split, some of the thicker ones being passed through the machine as many as five or six times; the skin and flesh side splits are usually sold to trunk-makers, the interior only being treated with the *sweetmeat*, as the lacquer is technically termed; this is principally composed of linseed-oil, with the addition of proper coloring matters. The skins, previously well dried and softened by beating and *boarding*, are stretched on frames, and the *sweetmeat* is applied in several coats; after each application the frames are slid into an oven heated by steam-pipes, where they remain until the varnish has set; any roughness that appears during any stage of the process is removed by polishing with pumice, and all traces of dust removed with a wet brush followed by a dry one. The entire operation requires from one to three weeks.

The variety known as *enameled* leather is finished by passing through a graining-machine having a heavy brass roller with a slightly corrugated face, and boarding in a peculiar manner by hand. See LEATHER.

Pat'e-ra. (*Architecture.*) An ornament on a frieze representing a round dish in bas-relief.

Pat'e-re'ro. (*Ordnance.*) A mortar for firing salutes.

Digitized by Google

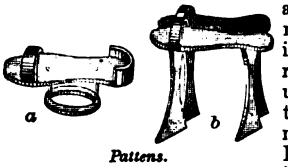
Pa'ter-nos'ter - pump. A *chain*-pump. So named from a fancied resemblance of the buttons on the chain to the beads of the rosary. The latter is an old invention of Central Asia, used by the Boodhists. See CHAIN-PUMP.

Pa'ter-nos'ter-wheel. A water-raising device having a number of buckets on a chain. Named from its resemblance to the rosary. See NORIA; CHAIN-WHEEL.

Pa'tio-pro'cess. The patio-process of amalgamation is practiced in Peru and Mexico. A *patio*, or *amalgamation floor*, is a large paved area, walled around to contain the *tortas*, or flat, circular heaps of ground ore, salt, magistral, etc., which are tramped by horses, treated by mercury, etc., as described under AMALGAMATOR, page 75 (which see). The process was invented by Medina in 1557, and was introduced into Nevada with but indifferent success.

Pat'ten. 1. A clog or sole of wood mounted on a frame to raise the feet of a person above a wet or muddy pavement. The support is usually an iron ring. They are much used in some countries where *sabots* are not in vogue. The Dutch wade round in *wooden shoes* in their dairies and sculleries. The English and French of the wealthier class use *clogs;* the more humble class in England use *pattens* (*a*); in France, *sabots.* The Oriental ladies patter round in their baths and paved courts, wearing *kübkobs* (*b*), to protect the soles of their delicate feet.

Fig. 3568.



Pattens.

2. (*Masonry.*) *a.* The sole for the foundation of a wall.

b. The base ring of a column.

Pat'tern. 1. A piece of card-board, sheet-metal, or thin plank corresponding in outline to an object that is to be fabricated, and serving as a guide for determining its exact shape and dimensions; such are employed by workers in leather, textile fabrics, and other thin materials for cutting out work, and also by wood-workers for laying off the outlines of objects of irregular form which are afterward shaped by the axe or saw. (See TEMPLATE.) Pattern-pieces or *gages* are largely used in making special machinery, such as rifles, sewing-machines, American watches, and numerous machines in which all the parts are made separately by gages and then *assembled.*

The system is known as *making by gages* and *assembling.* See GAGE; ASSEMBLING.

2. (*Fabric.*) A design of figures, woven in cloth or printed thereon.

3. (*Founding.*) The counterpart of a casting in wood or metal from which the mold in the sand is made. When dry-sand or loam-cores are used to form the cavities in a casting, projections of suitable size and shape are affixed to the pattern to secure such cores in place. See PRINT.

Patterns are often made in two parts, sometimes in several parts, held together by steady-pins or dowels.

Straight-grained pine or mahogany is preferred for patterns of this kind; screws rather than nails are employed for joining the pieces. Foundry patterns are made somewhat tapering in those parts which have to enter deeply into the molding sand or loam, in order to facilitate their removal; this taper may amount to $\frac{1}{16}$ or $\frac{1}{8}$ of an inch to the foot, and in some cases even more.

Ordinary iron shrinks about $\frac{1}{8}$ inch to the foot in cooling; brass, $\frac{3}{16}$ inch; and this must be allowed for in the pattern. For this purpose a contraction rule is employed, giving measurements about one per cent in excess of the true length; this avoids the trouble of calculating the extra dimensions to be given the pattern in each particular case.

Wooden patterns should be well oiled and varnished. This preserves them and assists their free delivery from the mold, which is farther insured by rubbing them with black-lead. In their construction, sharp interior angles should be avoided as tending to cause a breaking down of the mold at that point and weakening the casting. Patterns, especially for small castings, are sometimes made of metal. These have the advantage of being more durable, but if of iron require to be taken good care of to prevent rusting. See list under FOUNDING; MOLDING.

For machine for pattern-making, see numbers of *American Artisan* for May and June, 1874.

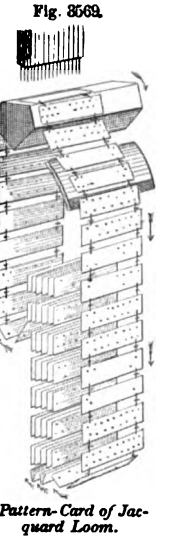
Pat'tern-box. (*Weaving.*) *a.* A box in a loom holding a number of shuttles, either of which may be projected along the shed, according to the pattern. The automatic means for operating the shuttles in due sequence is a PATTERN-CYLINDER or PATTERN-CHAIN (which see).

b. The box perforated for the harness-cards in the Jacquard figure-loom. See PATTERN-CARD.

Pat'tern-card. (*Weaving.*) One of the perforated cards in a Jacquard loom through which the needles pass; the perforations are according to the pattern.

Fig. 3569 shows the pattern-cards and pattern-box detached from the loom. The box is perforated with as many holes as there are warp-threads, and rods connected with each thread are suspended over it. The pattern-cards are perforated to correspond with the figure to be woven. As the box revolves, carrying the cards successively over its faces, the rods drop down whenever the holes in the cards and box coincide, each rod lifting its own warp-thread. The cards are hung together in an endless belt, as shown in the figure. See also pages 1356, 1357.

Fig. 3569.



Pattern-Card of Jacquard Loom.

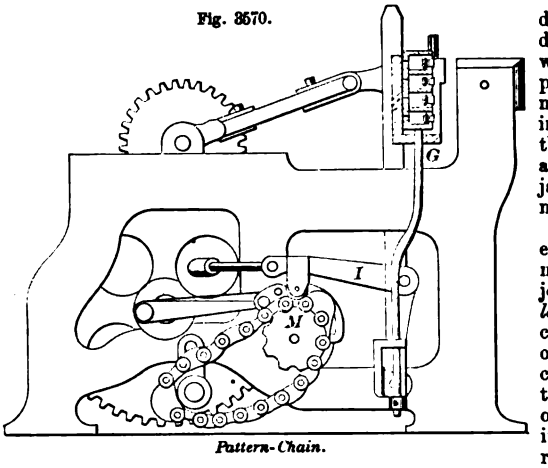
Pattern-chain. (*Weaving.*) A device for automatically bringing to the picker, according to the sequence required by the pattern, the shuttles in the shuttle-boxes at the ends of the race.

In Fig. 3570, the pattern-chain is shown passing over the wheel *M.* It has links of varying hight, which, as they pass beneath the roller on lever *I*, raise it to a greater or lesser hight, and with it the rod *G* and the shuttle-box at its summit, and so bring the required shuttle in position to be struck by the picker.

In Fig. 3571 the pattern-chain is shown beneath the levers *P*, from whose ends depend rods which control the movements of the lever *E.* This lever is connected by a link to a standard *F*, upon which latter the shuttle-boxes *B* are mounted, and is operated by two cams *H* and *I*, in such a manner as to raise or lower the standard upon which the series of shuttle-boxes are placed, so that any one of the boxes may be brought to the race from any position at every pick. The cams are actuated by a pawl and

Digitized by Google

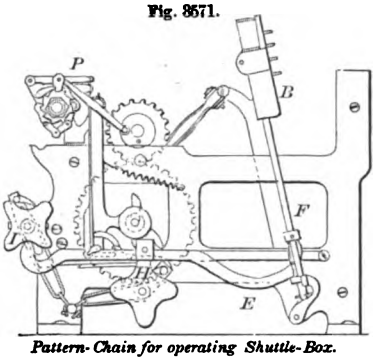
Fig. 3570.



Pattern-Chain.

ratchet connected by rods with levers *P* placed in contact with the revolving pattern-chain.

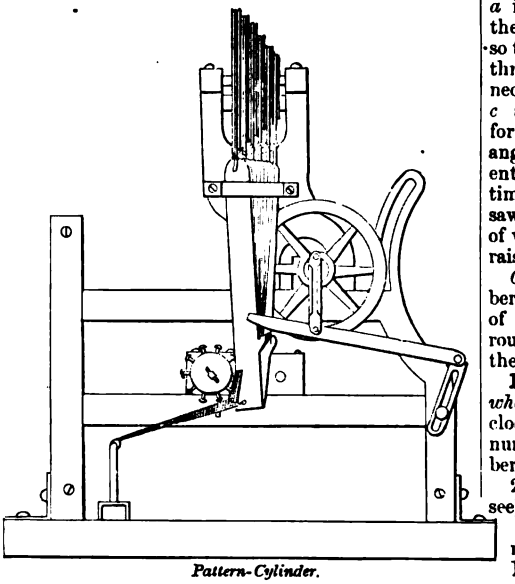
Fig. 3571.



Pattern-Chain for operating Shuttle-Box.

Pat'tern-cyl'in-der. (*Weaving.*) A means of operating the harness of a loom by means of a cylinder with projections which come in contact in due order of time with the respective levers which work the shed. In the example, the pattern-cylinder shaft is free at one end to admit of changing the cylinder readily for changing the pattern. The graduation in the sizes of the pulleys placed in series on the same shaft allows a true vertical pull upon each of the jacks, which are arranged side by side beneath.

Fig. 3572.

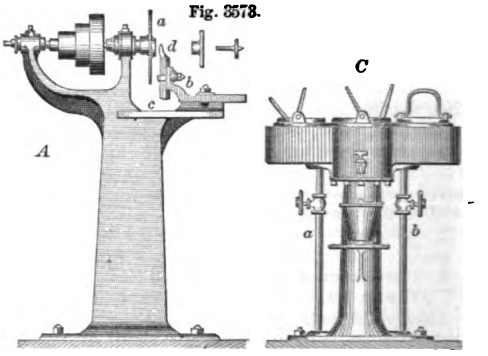


Pattern-Cylinder.

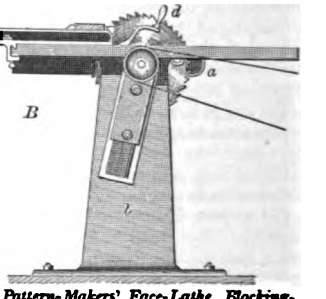
Pat'tern-mak'ers' Ap-pli'an-ces. These embrace various modifications of the tools and machines ordinarily used by the turner and joiner. Among others may be cited the *face-lathe* (*A*, Fig. 3573), for turning hubs, bosses, core-prints, etc. This is a compact machine, occupying a space of but two feet square; the cone-pulleys are of iron; the spindle of steel turns in brass bearings, and the face-plates *a*, of which two are provided, are capable of taking work up to 16 inches in diameter. The rest *b* is adjustable on the table *c* by a nut and screw, and the hight of the cutter *d* is also regulated by a screw.

B is a *blocking* and *cropping saw* adapted for cross

Fig. 3573.



cutting and slitting. The table *a* is pivoted on the standard *b*, so that it may be thrown back if necessary. Gages *c* are provided for varying the angle of presentation of the timber to the saw, the spindle of which may be raised or lowered by means of the wrench *d*.



Pattern-Makers' Face-Lathe, Blocking-Saw, and Glue-Heater.

C is a *steam glue-heater*. The pots, three in number, have flanges resting on the smooth upper surface of the heater, which consists of a water-bath surrounded by a steam-chamber. *a* is the steam and *b* the waste-water pipe.

Pat'tern-wheel. 1. (*Horology.*) The *count-wheel* or *locking-plate* of the striking portion of a clock-movement. That which has notches of such number or such distance as will determine the number of blows in regular order.

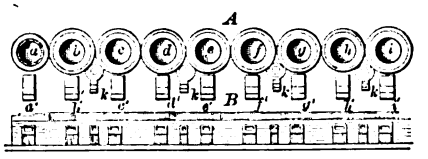
2. (*Weaving.*) A PATTERN-CYLINDER (which see).

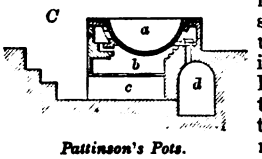
Pat'tin-son's Pots. (*Metallurgy.*) An arrangement invented by Mr. H. L. Pattinson of Newcastle-on-Tyne, about 1829, for separating

Digitized by Google

silver from lead. Lead ores always contain a small proportion of silver. By the ordinary process of cupellation, it does not pay to treat lead containing

Fig. 3574.





Pattinson's Pots.

less than 20 ounces of silver to the ton for the purpose of extracting the silver, but by Pattinson's process that containing as little as 3 ounces per ton may be profitably worked.

This process is based on the fact that the melting-points of alloys of silver and lead are higher in proportion to the amount of silver contained, and that if lead containing silver be melted and constantly stirred while gradually cooling, when it arrives at a temperature near the melting-point of lead, crystals will begin to form, which sink to the bottom, leaving the still fluid portion much richer in silver than the whole mass originally was, while, on the contrary, the crystallized portion has become poorer.

The apparatus consists of a series of eight or ten cast-iron pots set in a row, with fireplaces beneath. At the commencement of the operation one of the central pots, as *f*, is charged with lead from the calcining-furnace, which, when melted, is skimmed with a perforated ladle and the fire withdrawn; cooling is accelerated by throwing water on the surface of the metal, which is kept constantly agitated by means of a stirrer or slice. Crystals soon appear and fall to the bottom, whence they are removed by means of a perforated ladle and transferred to the pot *e* at the left; this operation is carried on until about two thirds of the charge has been transferred to the pot *e*, at which time, supposing the original charge to have contained 20 oz. of silver per ton, that remaining in the pot *f* will contain about 40 oz., and that removed to *e* but about 10 oz. per ton. The rich lead in *f* is then ladled into *g*, a fresh charge of calcined lead introduced into *f*, and the operation repeated, the richer metal being constantly transferred from one pot to another toward the right, while the poorer is passed from pot to pot in the reverse direction. In this way the crystals obtained from the pots to the left are gradually deprived of their silver, while those on the right are being continually enriched, the metal in the pot on the extreme right frequently being concentrated until it contains 500 oz. of silver per ton, while that in the pot on the extreme left should not contain more than 12 dwts. per ton.

A is the plan; *B*, the elevation; and *C*, a transverse section of the apparatus; *a* is the *market-pot*, from which the desilverized lead is ladled; *b c d e f g h i*, the *working-pots*; $a' b' c' d' e' f' g' h' i'$, their respective fireplaces; and *k k k k*, the *temper-pots*, in which the ladles are heated when they become cool.

In the section, *a* is a pot; *b*, grate; *c*, ash-pit; *d*, main flue.

The ladles, if operated by hand, are about 16 inches in diameter and 5 inches in depth; when cranes are employed much larger ones may be used.

Paunch. 1. (*Nautical.*) A thickly thrummed mat of sennit wrapped around a spar or rope to keep it from chafing.

2. The rim of a bell. The part against which the clapper strikes.

Paved Way. A tramway whose tracks are of stone.

Pave'ment. The hard covering of the surface of a road or foot-way.

According to Pliny (A. D. 79), "pavements are an invention of the Greeks." As usual, he forgets Egypt and is oblivious of India and China. Sosus of Pergamus (founded 283 B. C.) made ornamental mosaic pavements representing natural objects. The first Roman pavement in blocks of diamond (rhombal) form was laid in the temple of Jupiter Capitolinus during the third Punic war.

The Greeks invented (says the same author) terrace-roof pavements, and he gives the following directions for their construction:—

"Begin with two layers of boards crossing each other and nailed together at their extremities, to prevent warping. Next place a layer of pounded pottery and lime; upon this place a layer of broken pottery with a large proportion of lime, one foot thick and rammed. Another layer of pottery three parts, lime one part, is laid down, six fingers in depth. Square stones, two fingers thick, are laid on this on a slope of 1½ inches to 10 feet. Then polish the surface."

Pliny gives a formula for pavement which has the ordinary appearance of the ground when in the rough, but may be polished to resemble marble:—

Upon well-rammed ground place a layer of broken crockery, above this a layer of charcoal well trodden down with a mixture of sand, lime, and ashes, making the upper layer a depth of six inches.

Strabo informs us that the city of Babylon was paved at a very early date. The date assigned (2000 B. C.) is perhaps fabulous, though it was quite within the capacity of the builders of the city walls, palaces, and the bridge across the Euphrates, to pave the city in good style.

Isodorus says that the Carthaginians had the first paved streets, and that their example was soon copied by the Romans. Appius Claudius, the censor, constructed (312 B. C.) the road named after him, the Appian Way, which was, on account of its excellence, called the *queen of roads*. This was about ten years after the death of Alexander the Great. The time, however, when the streets of Rome were first paved cannot be determined with certainty. We are informed by Livy, that in the year of the city 584 (about 170 B. C.), the censors caused the streets to be paved from the ox-market to the temple of Venus.

The extravagant Heliogabalus caused the streets around the palace or on the Palatine Mount to be paved with foreign marble. Streets paved with lava, having deep ruts worn by the wheels of carriages, and raised banks on each side for foot-passengers, are found at Pompeii and Herculaneum.

Roman country roads were 8 feet wide on the straight lines, 15 feet at angles. Cattle might be driven on each side, if not fenced in.

Abderahman, the khalif of Cordova, Spain, caused the streets to be solidly paved, A. H. 236 (A. D. 950), and a man might walk after sunset ten miles in a straight line by the light of the public lamps. 700 years after this, London and Paris were unpaved and had no public lamps.

The capital of France was not paved in the twelfth century, for Rigord, the physician and historian of Philip II., relates that the king, standing one day at a window of his palace near the Seine, and observing that the carriages which passed threw up the dirt in such a manner that it produced a most offensive stench, his majesty resolved to remedy this intolerable nuisance by causing the streets to be paved, which was accordingly done. The orders for this purpose were issued by the government in the year 1184, and upon that occasion, it is said, the name of the city, which was then called Lutetia, on account of its dirtiness, was changed to that of Paris. In 1641, the streets in many *quartiers* of Paris were not yet paved.

Dijon, at that time reckoned one of the most beautiful cities of France, had paved streets as early as 1391; and it is remarked by historians that after this period dangerous diseases, such as dysentery, spotted fever, and others, became less frequent in that city.

The streets of London were not paved at the end of the eleventh century. It is related that in the

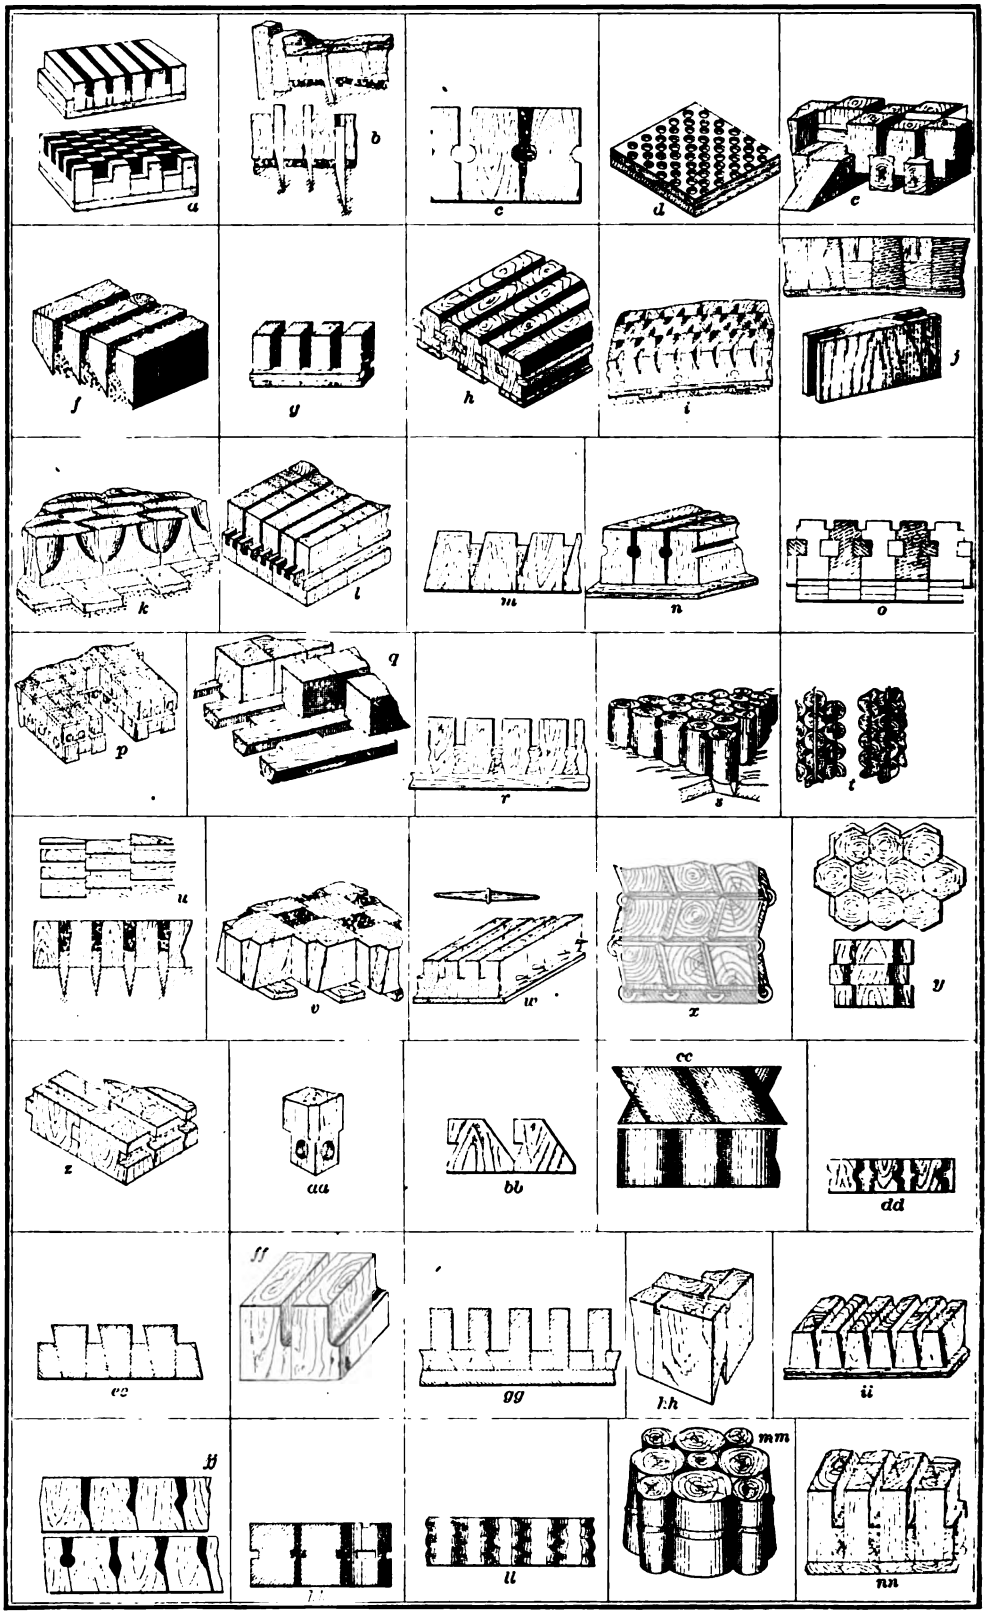

PLATE XXXVIII.] WOODEN-BLOCK PAVING. See page 1639.

Digitized by Google

year 1190 the church of St. Mary le Bow, in Cheapside, was unroofed by a violent wind, and that four pillars, 26 feet in length, sunk so deep into the ground that scarcely four feet of them appeared above the surface of the soft earth forming the bed of the street.

The pavements of this great city appear to have been gradually extended as trade and opulence increased, though the period of their first introduction is unknown. Several of the principal streets, among which was Holborn, were paved for the first time in 1417. Smithfield cattle-market was first paved in 1614.

Blocks of wood set endways are a common pavement in Russia and Germany. Blocks of wood or stone inclosed in iron frames were in use in England thirty or forty years ago.

In 1812, Loudon suggested laying cubic blocks on a foundation of flag-stones, or cast-iron plates on a bed of mortar.

George Knight (Loudon, P. 3720), London, 1829, suggested laying the granite blocks on a macadamized foundation. This, with grouting for rendering the pavement water-tight, and with under-drainage, is pronounced by Loudon one of the best modes of paving.

Lieutenant Brown (England, 1830) suggested a gravel foundation, dressed blocks of granite laid in mortar and grouted.

One form of the London pavement has granite blocks 6 × 4 inches on a bed of gravel, filled in with grouting, and solidified by a hot liquid cement of gas asphalt.

A part of Broadway, between Chambers and Warren Streets, was laid in 1835 with hexagonal wooden blocks. Various foundations were tried: cobble-stones, flagging, and macadam. The upper surface of the pavement was coated with a layer of tar and gravel.

An English patent, 1838, describes tapering wooden blocks boiled in tar and doweled together.

A subsequent English inventor aggregated his blocks in clusters in iron frames, which were fitted together.

In Parkin's English patent, 1840, the blocks are placed at angles of from 40° to 70°. The surfaces of the blocks were channeled, and they were cemented together in the pavement, their interstices being filled with pitch. Sand or ashes and tar was used in the foundation.

Previous to 1841, a system of foundation-boards was exhibited in New York, and in 1841 the blocks were interlocked by notched shoulders.

A pavement has been suggested, composed of iron perforated in such a manner as to afford a footing for horses, and to permit the sweepings to fall through upon a sub-pavement made of cement and depressed at the center, so that the offal can be swept therefrom to the sewers by simply flushing with water. It is said to have been put in operation in St. Louis. Cost, $3.66 per square yard.

Knight's patent consisted of blocks made of iron run into molds packed with hot granite fragments. This saved metal, which nevertheless could be run into form, and the granite gave the requisite roughness to the wearing surface.

Among the pavements now in common use may be enumerated: —

Ashlar, consisting of squared blocks of stone, generally granite, usually 12 inches deep, 8 to 12 long, and 5 to 7 wide.

Asphalt, a foundation of coarse broken stone and a top dressing of finer stone and perhaps sand or gravel, all cemented together by an asphalt.

Belgian, similar to ashlar, but of smaller blocks.

Bowlder, irregular stones brought to a comparatively even surface by resting on an uneven foundation of sand or gravel.

Cobble, stones naturally rounded, and of nearly equal size, rammed down in a bed of sand.

Concrete, similar to asphalt, except that tar or pitch is used, sometimes in conjunction with natural asphalt.

Granite, blocks of granite, either ashlars or irregular broken stones from the quarry.

Slag, refuse from the furnace, sometimes concreted; at other times run into molds to form blocks.

Wooden, blocks sawed to an even length, set endwise to the wear of travel.

Macadamizing was named from the inventor, and introduced in 1824. It consists in substituting broken granite for gravel as a top dressing, and is much superior to the latter for country roads, but will not stand the heavy wear of city travel.

Haussmann laid 1,250,000 yards of macadam in the streets of the city of Paris, as a substitute for the stone blocks, the material of barricades in revolutions.

In the *Snow* pavement no natural asphaltum is used; the raw coal-tar is treated with sulphuric acid, and mixed with lime and cement, and is said to produce a compound similar to the Neufchatel rock.

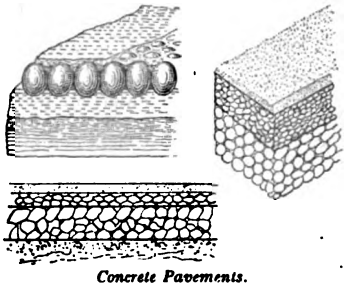
The *Scharff* pavement uses bitumen and the heavy tar-oils for the base, bitumen and a small quantity of natural asphaltum for the top courses.

The *Vulcanite* pavement makes Trinidad asphaltum the basis of the composition, treating the same with sulphuric acid or sulphur and cement.

The *Neufchatel rock* pavement has a base of a concrete of broken stone and bituminous or asphaltic compounds. This base being perfectly dry, a coating of that peculiar formation known as the Neufchatel rock, and which is a natural and intimately combined mixture of asphaltum with calcareous matter, is spread in a powdered state, well heated, and compressed by beating down with heated cast-iron pestles into a hard, smooth mass. The compression is completed by heavy rollers.

Fig. 3575 shows three varieties of concrete pavement.

Fig. 3575.



Concrete Pavements.

Solid concrete and asphaltum pavements are hard and elastic; are not affected by the alternations of heat and frost; they have no joints to encourage the growth of weeds and accumulation of filth; are therefore free from dust and mud. They dry in a few moments after a rain, are smooth, and yet not so even as to become slippery, especially when occasionally sprinkled. They afford an easy, noiseless, and pleasant drive; decrease the cost of keeping the street in repair, by confining the latter to the top dressing; and effect a large annual saving in horse-flesh and wear and tear of vehicles.

The *Nicolson* pavement, which was among the first wooden pavements used extensively in this country, consists of a foundation of boards laid flat upon the ground, and a superstructure of blocks sawed to an even length of 4 to 6 inches, and 2½ or 3 inches thick. The blocks are laid across the street, and secured by a thin strip of board nailed at the bottom, reaching not quite to the surface. The space thus left above the strip is filled with fine gravel, to afford a holding surface to horses' feet. The whole then receives a top dressing of tar. Another form has alternate short blocks, the spaces filled with gravel.

Numerous varieties of wooden pavement have been patented in the United States, and some of them are very extensively used. Plate XXXVIII. shows forty varieties of patented pavement. The difference between them lies in the form of blocks, method of laying, foundation, and chemical treatment or otherwise of the wood.

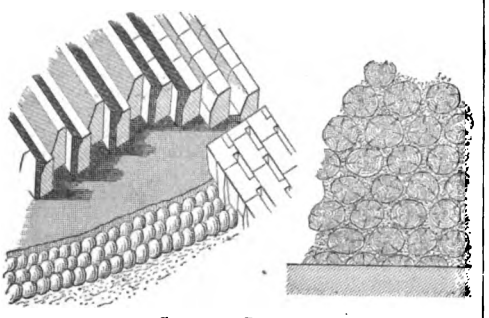
The greatest enemy to wooden pavements has been dry-rot from below. The surface of a well-laid pavement soon becomes water-proof from dust beaten into the pores of the wood, and if sufficient incline is given to the surface rain will flow off as from a roof. Dampness from below is drawn into the blocks by capillary attraction, and the lower part of the blocks crumbles into dust while the shell on top remains perfect. To prevent this decay, compound pavements, which exclude the absorption of the moisture of the soil by means of a layer of asphalt, would seem to offer more chances for duration than

Digitized by Google

any other system, especially if the wood has been chemically treated.

Of these compound systems used, two forms are shown in Fig. 3576, one employing square blocks

Fig. 3576.



Compound Pavements.

and the other round blocks on a concrete foundation. See WOOD, PRESERVATION OF.

Pa-vil'ion. (*Music.*) Fr. *Pavillon*, from its tent-shape. The flaring mouth of a horn, trumpet, or wind-instrument of that class. The insertion of the hand into the *pavilion* of the French horn regulates the inflection of the sounds.

2. (*Architecture.*) *a.* An isolated building of ornamental character.

b. A turret rising from the general hight of a building.

c. A projecting apartment of a building.

d. A tent-shaped roof.

3. A tent; a marquee.

4. (*Gems.*) The part of a diamond or other gem below the *girdle* and between it and the *collet*.

Pa-vil'ion-chi-nois'. (*Music.*) An instrument having a number of small bells in a frame, which is agitated by striking the staff on the ground. It is especially used in marching music.

Bells, *high* and *low*, are used in military music, and occasionally for dramatic effects in operas.

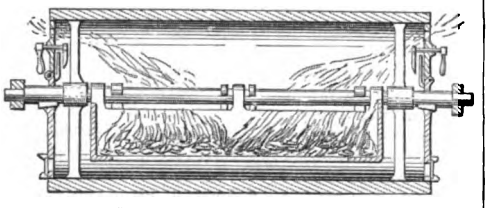
The *glockenspeil* is an instrument in which bells are rung by keys; in one case bars of steel are substituted for bells.

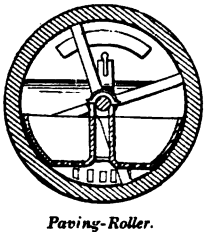
Gongs and *triangles* are but forms of bells.

Pav'ing-bee'tle. A rammer used by paviors.

Pav'ing-ma-chine'. A traveling rammer, like

Fig. 3577.





Paving-Roller.

a small pile-driver, traveling over the surface of the pavement and ramming down the blocks, was invented about 1830 by Colonel Macirone, London.

A steam paving-machine in use in Paris consists of a small steam-engine on wheels, drawn by one horse, to the rear of which is attached the pavior or vertical rammer, which is forced upon the ground with great force by a blow from the piston. It slides on a bar some six feet long, and can thus be directed by the driver to any stone which requires forcing home.

Lignier's machine (French) consists of a small Lenoir steam-engine, to the fly-wheel of which is attached a rammer of steel, smaller and heavier than the wooden one in general use. The operator simply guides the strokes of the machine.

Pav'ing-roll'er. A heated roller for compacting asphalt pavement. In the example, a cresset or fire-basket is suspended within the roller in such a way as to preserve its proper position during the rotation of the roller.

Pav'ing-tile. A flat brick for paving floors. Such are often of an ornamental character, enameled, encaustic, etc. See TILE.

Tiles employed in offices, kitchens, etc., are usually from 9 to 12 inches square.

Pa'vi-or. 1. A paving-brick.

2. A rammer for driving paving-stones.

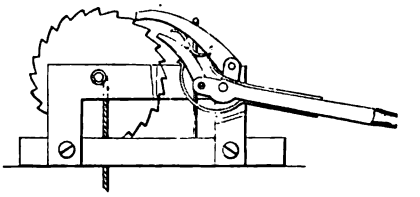
Pawl. A pivoted bar adapted to fall into the notches or teeth of a wheel as it rotates in one direction, and to restrain it from back motion. Used in windlasses, capstans, and similar machinery. The pawl acts by gravitation or by a spring.

The same device is called a *click* when acting in connection with a ratchet-wheel, as in the winding part of a watch.

It is sometimes called a *detent*. This is its office, but the thing has already names enough.

Figs. 3578, 3579, 3580, show three applications

Fig. 3578.



Pawl in Hoisting-Apparatus.

of the pawl, and many others may be found incidentally shown in connection with devices, such as *click*, *ratchet*, etc.

Fig. 3578 is a hoisting lever having a pair of pawls acting upon a ratchet on the shaft of a windlass.

Fig. 3579.

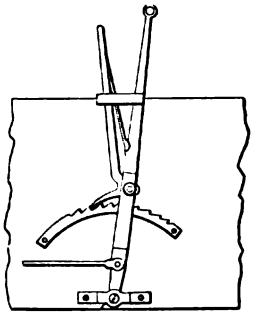
Pawl in Harvester-Wheel.

Fig. 3579 shows the pawl and ratchet gear of the driving apparatus of a harvester. As the machine moves in a curve, one of the propelling wheels will revolve faster than the other, and the link which connects the pawl with the friction-band is silently disengaged from the teeth of the case on the outer curve. When the machine turns a curve in the opposite direction, the pawl is made to engage with the teeth.

Digitized by Google

Fig. 3580 shows the application of a click and ratchet holding-device for a wagon-lock. A handle, which is secured to the pawl, extends upward and slides in a guard attached to the brake-lever. It is used to release the pawl from the ratchet.

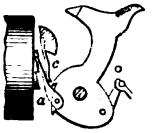
Fig. 3580.



Pawl on Wagon-Lock.

The mode of rotating the barrel of the Colt pistol is by means of a pawl pivoted to the lower part of the hammer, and acting upon a crown ratchet on the rear of the barrel. As the hammer is brought to the cock, the pawl *a* rises, being kept to its work by a spring *c*, which forces it into the interdental spaces of the ratchet. As the hammer falls, the pawl slips and takes hold of the next ratchet-tooth.

Fig. 3581.



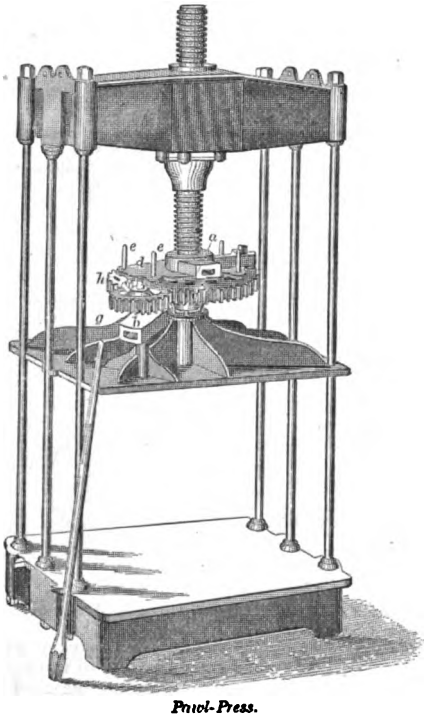
Feed-Motion of Colt's Pistol.

Pawl-bitt. (*Nautical.*) A timber opposite the middle of the windlass supporting the pawls which engage the ratchet of the barrel.

Pawl-post. (*Nautical.*) A timber to withstand the thrust of the pawls of a windlass. A *pawl-bitt*.

Pawl-press. A standing press used by bookbinders and printers for pressing sheets, etc. It is next in power to the hydraulic press, and is operated by a lever inserted into the sockets *a b*, and another not shown. The plate *d* has beveled pins *e*, which drop into the beveled slots *f* when the lever is turned, so as to produce a downward motion of the screw, and rise therefrom when it is turned in the opposite direction; pawls are also caused to engage the smaller wheels *g h*, each of which in turn serves as the driver, by inserting the lever into an appropriate socket, the smallest wheel when thus employed affording the greatest power.

Fig. 3582.



Pawl-Press.

Pawl-rim. (*Nautical.*) A notched cast-iron rim encircling the barrel of the windlass, and serving for the pawls to catch in.

Pay. (*Nautical.*) *a.* To cover or fill with a water-proof composition or substance, as the bottom of a vessel, a seam, a mast, yard, or rope. The materials used are tar, pitch, tallow, resin, etc., or combinations of them.

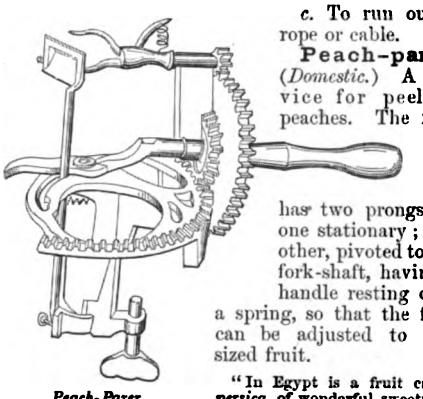
Weather-decks are *payed* with marine glue; a solution of caoutchouc and shellac with naphtha.

Decks are payed with a ladle; seams, with a ladle or mop; other surfaces with a brush.

b. To fall off from the wind.

c. To run out a rope or cable.

Fig. 3583.



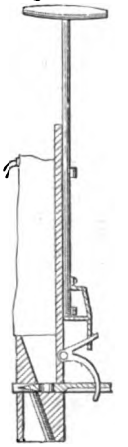
Peach-Parer.

Peach-par'er. (*Domestic.*) A device for peeling peaches. The fork has two prongs, — one stationary; the other, pivoted to the fork-shaft, having a handle resting over a spring, so that the fork can be adjusted to any sized fruit.

"In Egypt is a fruit called *persica*, of wonderful sweetness. This was brought out of Ethiopia by the Persians when Cambyses conquered these places."— Diodorus Siculus (60 B. C.).

Rather say, brought by the Persians from home. They brought little with them from Ethiopia except disgrace. The peach (*persica*) is Persian. It was introduced from the East into Europe by the Arabs. Its congeners, the nectarine and apricot, are also natives of Asia.

Fig. 3584.



Pea-Dropper.

Peach-ston'er. An implement for thrusting the stone out of a peach while holding the fruit; or, with free peaches, dividing the fruit, so that the pit may drop out. In one case, the peaches are fed between wheels with corresponding concave faces and drawn against knives, which open the peach and deliver the halves and the stones at different places.

Pea-drop'per. (*Husbandry.*) An implement for planting pease in hills. It resembles the corn-planter in material respects.

With the down stroke the elbow-lever is vibrated, pushing the slide and its contents over the dropping-hole, whence it falls into the ground. As the handle and implement are raised, the slide returns and is refilled.

Peak. 1. (*Nautical.*) *a.* The upper, after-corner of a *trysail*, *spanker*, or *sprit*-sail.

Digitized by Google

b. The upper end of a *gaff*. The national ensign is flown at the *peak*.

c. To *top* a gaff or yard more obliquely.

d. To raise the oars upright amidships.

e. The pointed *bill* beyond an anchor's *palm*.

2. The leathern front of a cap.

Peak-arch. (*Architecture.*) A pointed, or *Gothic* arch.

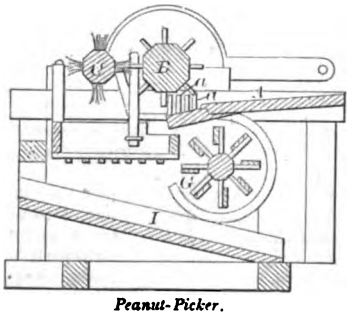
Peak-hal'yards. (*Nautical.*) The purchase by which the peak of a gaff is raised. The throat which rests against the mast has its *throat-halyards*.

Pea'nut-dig'ger. A kind of plow with trailing branches, which raises from the soil the vines with the nuts attached, and leaves them strung upon the surface of the ground, to be afterward gathered and picked by hand or by machine.

Pea'nut-pick'er. A machine for separating peanuts or the pods of leguminous plants from their vines.

These are fed down the incline *A*, and, in passing between the spoked cylinder *B* and upright teeth *a a*, the pods are torn from the stalks and fall upon a sieve to which a vibratory motion is imparted by a lever and a cam on the cylinder *B*. A

Fig. 3585.

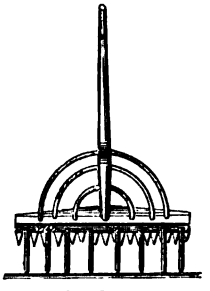


Peanut-Picker.

strong blast directed from the fan *G* above and below the sieve blows away the vines, while the pods fall through upon the incline *I* and are delivered into a proper receptacle. A rotary brush *C* clears the spaces between the spokes on the cylinder *B*.

Pea-rake. A rake adapted for gathering the field pea.

Fig 3586.



Pea-Rake.

The toothed cutter on the rake-head cuts off the vines which the rake has gathered.

Pear-gage. A gage for measuring the exhaustion of an air-pump receiver. It consists of a tube open at bottom and held by a wire passing through the top of the receiver, so that after exhaustion it may be lowered into a cup of mercury, the degree of exhaustion being shown by the hight to which the mercury rises when the air is readmitted.

Pearl. (*Printing.*) A size of type between Diamond and Agate.

Diamond, 205 ems to a foot.
Pearl, 178 ems to a foot.
Agate.
Nonpareil, 143 ems to a foot.

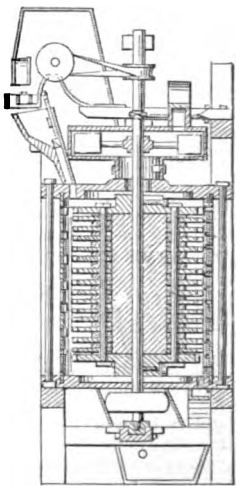
Pearl, Ar'ti-fi'cial. A hollow glass bead internally coated with a pearly film derived from the scales of certain fish.

Pearl-ash. A somewhat impure carbonate of potash obtained by leaching wood-ashes.

Pearl-bar'ley Ma-chine'. A machine for taking the hull from barley grains.

The grain is placed in one of the two hoppers, and passes through the annular space between the toothed cylinder and the case. The cylinder has horizontal toothed rings alternating with plain ones. The shell has holes with the burrs inside, and oblique slots which incline to the right and left, to operate when the cylinder is turned in either direction, according as the grain is furnished by one or the other hopper. An adjustable fan-blast removes the husks from the machine. From the elevator the grain passes over a screen which keeps back the unhusked grain, and the same is returned to the alternate hopper.

Fig. 3587.



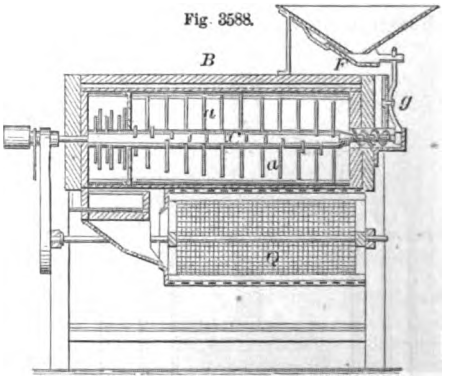
Pearl-Barley Machine.

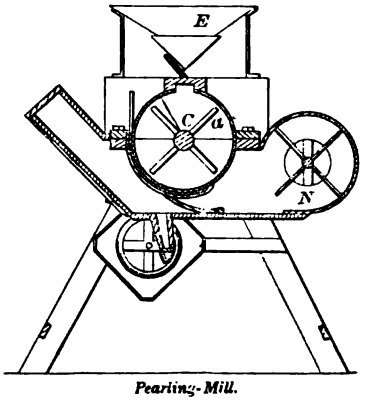
Pearl-but'ton. A button made of a shell. The blanks are cut out by a revolving steel tube with a serrated end; it forms an annular saw, like a *crown* or *trepan* saw. The blanks are then split by taking advantage of the laminar structure of the shell, placed in a spring chuck, faced and backed by a turning tool, drilled, and polished by rottenstone and soft-soap.

Pearl'ing-mill. A mill for preparing hominy, pearling barley, etc.

The grain is fed from a hopper *E*, and passes down an incline

Fig. 3588.





Pearling-Mill.

Digitized by Google

F into the spout *g*, whence a screw conveys it into the cylinder *B*, which contains a rotary shaft *C* provided with spiral arms *a a*, by which the grain is beaten and gradually conducted to an opening at the other end of the cylinder, where it is exposed to the action of an air-blast from the fan *N*. It thence passes down the spout *P* to the screen *Q*. See HOMINY-MACHINE.

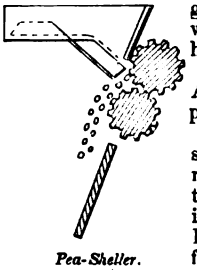
Pearl-pow'der. 1. A submuriate of bismuth, used as a flux for certain enamels.

2. A cosmetic of various compositions.

Pearl-white. A cosmetic. The submuriate of bismuth, obtained by precipitation from nitrate of bismuth.

Pease-meal. (*Foundry.*) Pease-flour, dusted on as *facing* on molds for brass-work. Used also sometimes to give tenacity to very weak sand when strong sand is not to be had.

Fig. 3589.



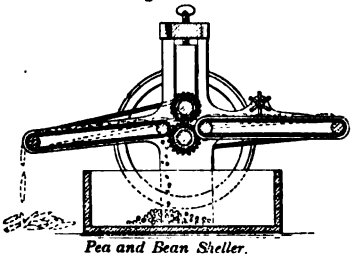
Pea-Sheller.

Pea-shell'er. (*Domestic.*) An implement for taking garden pease from their pods.

The sectional view (Fig. 3589) shows one form. The corrugated rollers grasp and burst the pod; the pease fly out, and the pod is carried away by the rollers. Brushes remove particles of pods from the rollers.

In Fig. 3590 the pods are fed by a belt between the elastic surfaces of two rollers, which burst them open, allowing the pease to fall into the tray while the empty pods are carried off by a discharging belt.

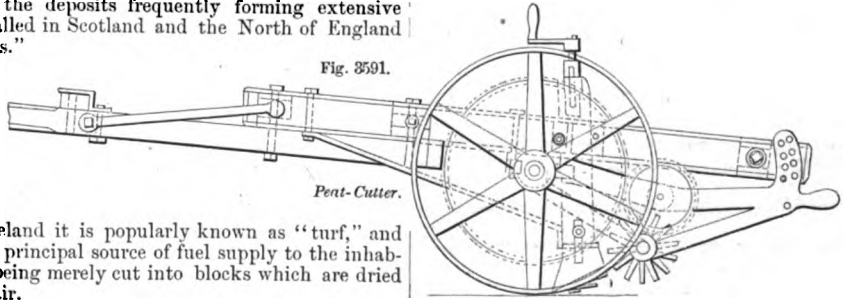
Fig. 3590.



Pea and Bean Sheller.

Peat. A carbonaceous substance formed by the decomposition of vegetable matter when the conditions as to temperature and moisture are favorable. The better qualities contain, when dried, from 45 to 50 per cent of carbon, the remainder consisting of water and inorganic substances; about half the water is chemically combined with the peat. It occurs but in small quantities or not at all in countries where the summer heat is so great as to cause rapid decomposition, and is largely found in such countries as Ireland, Holland, and North Germany, where the summer temperature is low and the air generally moist; the deposits frequently forming extensive bogs, called in Scotland and the North of England "mosses."

Fig. 3591.



Peat-Cutter.

In Ireland it is popularly known as "turf," and forms a principal source of fuel supply to the inhabitants, being merely cut into blocks which are dried in the air.

The peat of Ireland is estimated at 4,000,000,000 tons, and is used for fuel and for the production of naphtha, paraffine, etc.

The peat of Holland is deposited on the bottoms of ponds and lakes, — this may be equally true of peat-beds in general, — and is dredged up and spread on the ground to dry. After draining, it is consolidated by the pressure of flat boards fastened to the feet of men who walk over it. It is then cut into blocks and dried for fuel.

Peat forms an ingredient in many of the artificial fuels, being associated with coal-screenings, coke-dust, charcoal, cinder-siftings, pitch, sawdust, spent tan-bark, tar, crude petroleum, asphaltum, wood-shavings, corn-cobs, and other ingredients, in various quantities. Excepting as to the machinery involved, the question is a little outside of our limits.

Peat is prepared for use as fuel, —

1. By drying it in stacks in the open air, or better in sheds, where it is protected from rain but has free access of air. Air-dried peat contains 25 per cent of water.

2. By kiln-drying.

3. By compression. This has the effect of rendering it more compact and increasing the heat yielded by a given bulk. The compression assists the drying. Owing to the fact that peat is not homogeneous, the process of compressing peat in its natural state is a difficult one. It is consequently usually ground and lixiviated with water, to remove the mineral impurities previous to pressing. Various modes of effecting this are practiced in France, Holland, and Germany. These effect a very considerable reduction in the weight of the prepared material, but are objectionable on account of the addition of water, which has again to be dried out of the mass.

In the dry-compression process of Gwynne and Exter, the material is first deprived of its natural excess of water by means of a hydro-extractor, then pulped and dried; the product is then ground into powder, which is molded by pressure, heat being at the same time applied.

In another process the peat is dried in the air, ground to a coarse powder, then stove-dried, and finally pressed and molded.

The Lester and Halstead artificial fuel is composed of 60 to 65 per cent of peat, about 20 per cent of anthracite dust, 10 per cent coal-tar, 5 per cent asphaltum, but varying in proportion for different purposes, whether metallurgical, domestic, or other. The peat, dug in the usual manner, is laid in the air to dry; and when dry enough to be mixed with the other materials into an amalgam, it is put into a press, and with one blow compressed. Next day it is ready for use.

Peat-burn'ing Fur'nace. Three furnaces adapted for this fuel as well as coal are Bennett's, Washburn's, and Stillman's, described under AIR-ENGINE, page 39.

Peat-cut'ter. An implement of the nature of a plow or excavator, used for paring peat from the

Digitized by Google

upper surface of the stratum, for the purpose of treatment in the peat-machine.

The example shows a wheeled vehicle having a transverse slicing-knife 9, which, by the force of the draft, cuts and raises a broad belt of peat; this is delivered from the serrated rear edge of the apron behind the knife to the toothed breaker, which is revolved by gearing from the drive-wheels, and tears the peat to pieces.

Peat-ma-chine'. A machine by which peat, either alone or in combination with other inflammable materials, as coal-dust, is prepared for fuel.

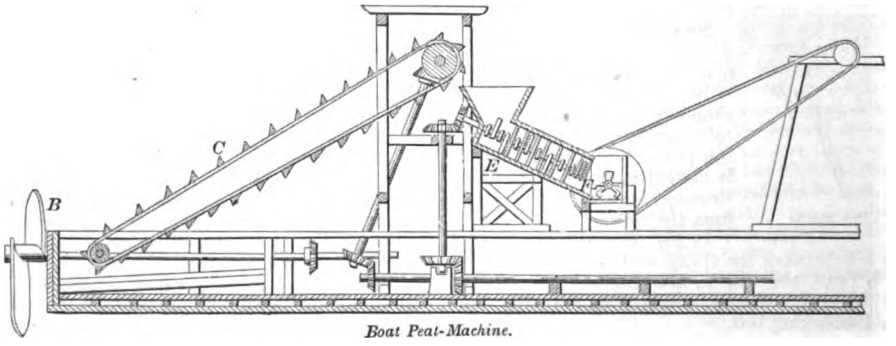
A large number of these machines has of late years been patented in the United States. These are more or less complicated, according to their special function, some being merely designed to cut the peat or to cut and break it, while others perform the whole series of operations by which it is delivered in the form of a densely pressed cake ready for drying and burning.

A few representative examples are shown.

Most of the peat-machines are merely grinders and pressers, which deliver the comparatively homogeneous and dry material in blocks. These machines are so like *brick-machines* that it would appear like duplication to repeat them here. See BRICK-MACHINE.

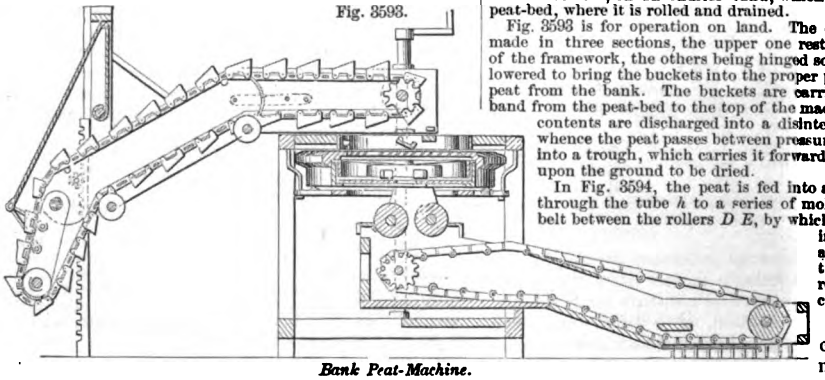
In Fig. 3592, the peat is cut by the screw-excavator *B* and delivered on to the endless belt *C*, by which it is carried to a hopper, where it is fed into the pulping-trough and separator *E F*. This is separated into communicating compartments, and has a shaft provided with radial arms by which the peat is comminuted, afterward passing into the pulping and distributing trough, which also contains a rotating shaft with radial arms, by which it is farther pulped, and deposited through an aperture at bottom, on an endless band, which conveys it to the peat-bed, where it is rolled and drained.

Fig. 3592.



Boat Peat-Machine.

Fig. 3593.

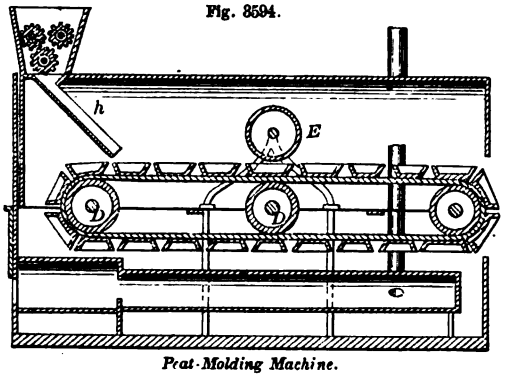


Bank Peat-Machine.

Fig. 3593 is for operation on land. The conveyor-frame is made in three sections, the upper one resting upon the top of the framework, the others being hinged so as to be raised or lowered to bring the buckets into the proper position to dig the peat from the bank. The buckets are carried by an endless band from the peat-bed to the top of the machine, where their contents are discharged into a disintegrating mill, from whence the peat passes between pressure-rollers, and falls into a trough, which carries it forward and distributes it upon the ground to be dried.

In Fig. 3594, the peat is fed into a hopper, passing through the tube *h* to a series of molds on an endless belt between the rollers *D E*, by which it is compressed into cakes; these are delivered from the molds at the rear end of the machine.

Fig. 3594.



Peat-Molding Machine.

Peb'ble. By custom, a lens made of rock-crystal.

Peb'ble-pav'ing. Pavement laid with pebbles from 3 to 4 inches deep. When larger stones are used, it is known as *bowlder*-paving, and is from 6 to 9 inches deep.

Peb'bling. (*Leather.*) An operation to bring out the grain of leather and give it a roughened or ribbed appearance. Formerly, the skin was doubled upon itself with the flesh side outward, and the contacting surfaces rubbed to and fro upon each other until the desired appearance was obtained; or a ball of suitable material, grooved or ridged, was passed over the hair side in various directions.

In the *pebbling-machine*, the skin is subjected to the action of a roller with a surface the reverse of the grain or pebble to be produced. This grain may be an imitation of some more costly piece, and skins with a peculiarly fine grain are sometimes electrotyped, to transfer the design with more fidelity to the roller. The machine has the roller

Digitized by Google

mounted on an oscillating arm, after the manner of the tool shown in LEATHER-POLISHING MACHINE (which see).

Peck'er. 1. (*Telegraphy.*) A *relay*. So called in England from the appearance of the earlier apparatus, which *pecked* like a bird.

2. (*Weaving.*) The *picker* of a loom. The shuttle-driver.

Peck'ings. *Place-bricks*, from the outside of the kiln and insufficiently burned. *Sandel* or *semel* bricks.

Ped'al. (*Music.*) A lever or key actuated by the foot. In the piano, the soft pedal shifts the *bank of keys*, so that the hammers do not strike all the keys of the *course of strings*. The other pedal raises the damper so as to allow a more sonorous vibration of the strings.

In the organ, the pedals open and close certain pipes. In the parlor-organ or melodeon, the pedal works the bellows.

When it is used in machinery, as in working a lathe or a sewing-machine, it is called a *treadle*.

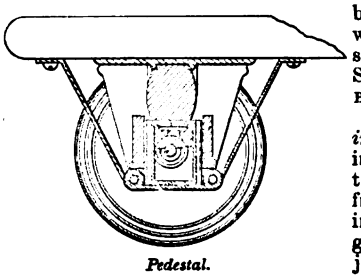
Pedals were first used on organs. (See ORGAN.) About the middle of the eighteenth century they were adopted as a means of working the *stops* of the harpsichord. These were known as the *forte*, *soft*, and *buff*. See STOP.

Ped'al-key. (*Music.*) The *pedal*-keys of an organ are worked by the feet, the *manual*-keys by the hand.

Ped'al-or'gan. (*Music.*) That part of a large organ which is played by foot-keys, enabling the larger pipes to be operated by the feet of the performer.

Ped'es-tal. 1. (*Machinery.*) The standards of a pillow-block, holding the brasses in which the shaft turns. See PILLOW-BLOCK.

Fig. 3595.



Pedestal.

2. (*Railroading.*) A casting secured to the truck-frame and having vertical guides for the journal-boxes of the axles, which rise and fall in the pedestals as the springs collapse and expand.

3. A pillar, post, or column.

4. A plinth, base, or foot for an object to be raised and displayed. When perfect in its parts, it consists of a *base*, *die* or *dado*, and *cornice*. A stylobate.

Ped'es-tal-cov'er. (*Machinery.*) The cap of a pillow-block, which is fastened down upon the pedestals and confines the *boxes*. See PILLOW-BLOCK.

Ped'i-ment. (*Architecture.*) A triangular structure at the termination of a roof, or over a portico, window, or doorway, differing from a mere gable in having a horizontal and two raking cornices, inclosing a tympanum.

Ped'i-ment-ba-rom'e-ter. A barometer whose case is surmounted by a pediment for the purpose of ornamentation.

Pe-dom'e-ter. A *pace-measurer*. An instrument to count the steps.

One form consists of a string with a piece of lead at the end, and knotted at distances of 44 feet apart. It is to be used in connection with a seconds watch. Forty-four feet bears the same relation to an English statute mile (= 5,280 feet) that $\frac{1}{2}$ minute does to an hour; that is, the knots are $\frac{1}{120}$ of a mile apart. Drop the lead and allow the string to pass through the hand, the number of knots slipping through the hand indicate the rate of walking in the number of miles per hour.

Small *pedometers*, to be worn on the person, consist of a train of wheels in a small case, and a dial which registers the number of impulses derived from a cord attached to the foot. In this form it becomes a register of the number of *paces*.

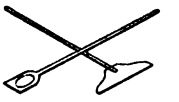
Payne's *pedometer* (English patent, 1831) was of the form and size of a common watch, having a pendulum which was swayed by the movement of the person in walking; the pulsations being registered in the usual way and shown on the dial. The patentee also attached his pedometers to an ordinary watch, in which case the train of wheels and other parts are placed under the dial-plate or face of the watch.

Pee. The point of an anchor-arm which penetrates the ground. The *fluke* or *palm* is the expanded portion which affords an area of holding surface. The *bill*.

Peek. (*Nautical.*) The upper end of a fore-and-aft sail, sprit-sail, etc.; or the outer end of a gaff. See PEAK.

Peel. 1. (*Bakery.*) A wooden shovel with a long handle, used by bakers in putting in and withdrawing loaves to and from the oven.

Fig. 3596.



Peels.

2. A similarly shaped implement for hanging wet sheets of paper on lines or lath to dry.

3. (*Nautical.*) The *wash* of an oar. The end inside the gunwale is the *loom*.

Peel'ing-i'ron. A shovel-shaped thrusting-instrument whereby bark is loosened and pried away from the wood. See BARKING-TOOL.

Peen. The sharp point of a mason's hammer. Sometimes incorrectly written *pane*.

Fig. 3597.

Hammer-Peens.

a, narrow peen for riveting.
b, broad peen for machinists.
c, cross peen for coopers.
d, cone peen for chasing
e, ball peen; upsetting hammer for engravers.

Peg. A wooden nail or pin.

1. (*Shoemaking.*) A small pin of wood (maple) for securing the *upper* and *counter* to the *sole* of a boot or shoe; and for securing the extra *sole* to the upper one, or the *lifts* of the *heel-tap* to each other in *building-up* the heel.

Copper-wire pins have been substituted; also small pins of leather; also screw-pegs.

The term gives rise to many compound words, — pegging-awl, peg-making machine, peg-driver, peg-float, peg-cutter, etc.

Fig. 3598 shows a number of different kinds: —

a has pegs glued to paper, so as to admit of being fed in a ribbon.

b shows a plain and a notched peg, which is designed to be saturated with shoemaker's wax.

c is a peg-strip in which a ribbon of wood is cut out with one sharp edge, the pegs being separated therefrom in the pegging-machine by a chisel and driven by a blow.

d d' d'' d''' are pegs of condensed leather, nearly separated but adhering sufficiently to be fed as a strip.

e is a barbed peg.

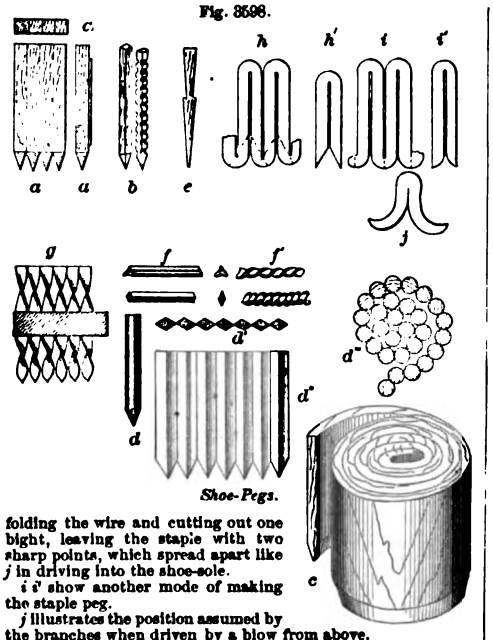
f f' are pegs made of wires of various angles and twisted.

g shows a row of cable-screw pegs soldered on to a metallic ribbon for feeding in a pegging-machine.

h h' are modes of making staple pegs for boots and shoes by

Digitized by Google

Fig. 3598.



Shoe-Pegs.

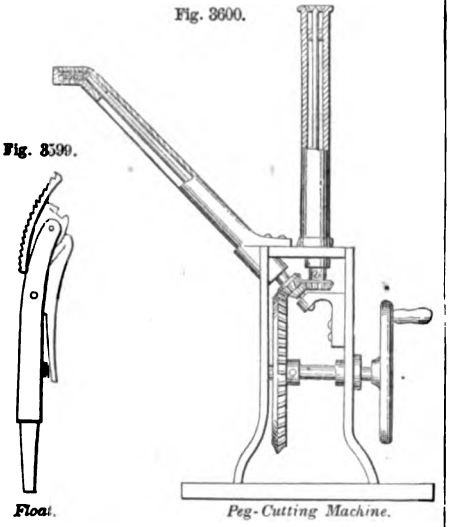
folding the wire and cutting out one bight, leaving the staple with two sharp points, which spread apart like *j* in driving into the shoe-sole.
i i' show another mode of making the staple peg.
j illustrates the position assumed by the branches when driven by a blow from above.

2. (*Music.*) A turn-pin on which a string of a musical instrument is stretched.

Peg-cut'ter. An instrument or machine for removing the ends of pegs from the insides of boots and shoes. A *float*. In the example this is pivoted in the stock and has a flange beneath, in one of whose notches the spring dog is engaged to main-

Fig. 3600.

Fig. 3599.



Float. *Peg-Cutting Machine.*

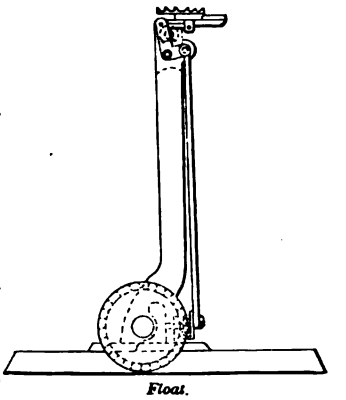
tain the *float* in the required angular position. The stock stands in a hole in a bench.

In Fig. 3600, the cutters at the ends of the shaft have a rotary motion, imparted by gearing and a hand-crank.

Peg-float. An implement for rasping pegs from boots and shoes. In the example, the cutter, instead of being worked directly by hand, is reciprocated by a crank-wheel, connecting-rod, and elbow-lever.

Peg'ging-awl. (*Shoemaking.*) A stiff awl with a four-sided blade, approximating the shape of the peg which is to occupy the hole. It is driven by a hammer.

Fig 3601.



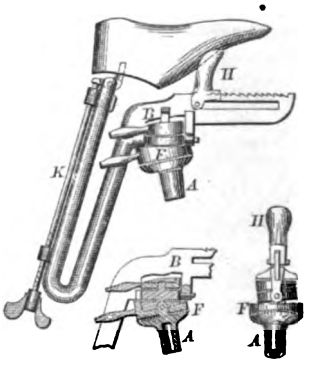
Float.

Peg'ging-jack. An implement for holding a boot or shoe and varying its position while being pegged.

In the example, the latter object is effected by varying the position of the curved arm on the standard *A* by means of cams with handles *B F*. The adjustable pad *H* supports the forepart of the last, while the heel may be tipped by means of the threaded rod *K*.

Peg'ging-ma-chine'. An apparatus for driving the pegs which unite the soles and uppers of boots and shoes. The pegs are usually cut from what is called a peg-strip, which is a ribbon of wood,

Fig. 3602.



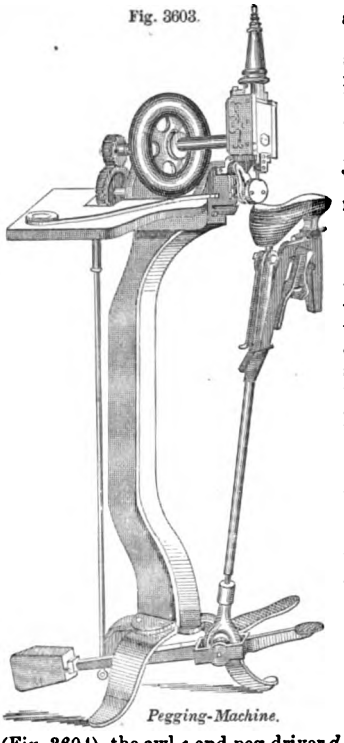
Pegging-Jack.

the grain running across the width of the strip, and fed to the parts which cut off a peg and then drive it.

In the illustration, the long jack-standard is hinged by a universal joint in the foot-lever, which is weighted at one end to hold the shoe in contact with the pegging and feeding devices, and at the other with a stirrup or foot-rest to disengage the finished shoe. The jack is capable of lateral and longitudinal motions upon the standard, to present the surface of the sole at the point of contact with the pegging-devices in a horizontal plane. The vertical plunger, carrying an awl and a driver, is operated by a cam and gearing. The rotary feed is immediately back of the peg-guide, and operated by a pawl and ratchet receiving motion from the main gearing in any suitable manner, ordinarily by a cam. The peg-strip is fed into the guide from a coil of practically indefinite length and from which a peg is cut

Digitized by Google

Fig. 3603.



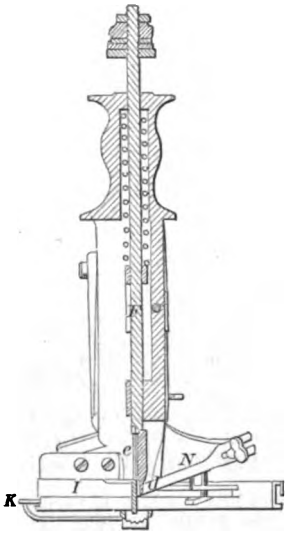
Pegging-Machine.

at each fall of the driver, by a lateral knife, immediately before being driven into the shoe. The long jack-standard brings the mechanism near the eye of the workman.

The two requisite conditions are that the point of contact of the shoe-sole with the pegging-devices must be the center of motion of the work for the time being; and, secondly, the surface of the sole at the point of contact with the pegging-machine must be kept in a horizontal plane.

In Goddu's (Fig. 3604), the awl *e* and peg-driver *d* are simultaneously operated by a spring actuating the plunger *F*, to which they are both attached. The strip of pegs, placed in a feed-trough *I*, is advanced by a follower *K*, and each peg is separated by a flexible knife *N*, which also holds it in position for being driven.

Fig. 3604.

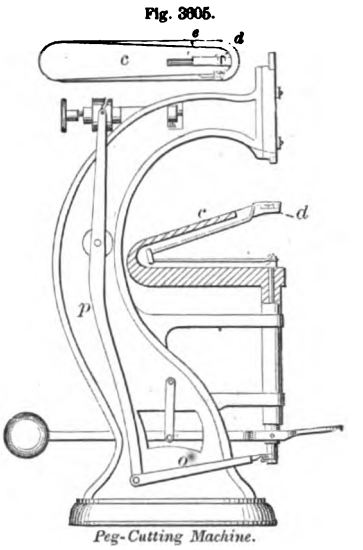


Pegging-Machine.

The device, Fig. 3605, is for cutting off the projecting ends of pegs within the shoe during the process of pegging. The shoe-supporting horn *c* has a slot *d* in which works a knife *e*, operated by a combination of levers *o p*, the upper member of which has a projecting pin working in a slotted cam-shaft.

Sargent's machine is particularly designed for shoes, of which the uppers and soles are united by screw-threaded wire cut to proper length during the operation of pegging. This is effected by a circular cutter connected with a rock-shaft. As the nails are cut off they descend through a peg tube, assuming a vertical position, and are driven home by a plunger actuated by a spring *a* and retracted by a pin on the wheel *b* engaging a shoulder on the plunger.

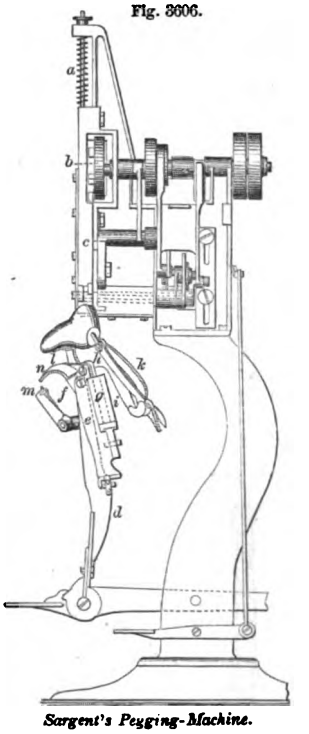
Fig. 3605.



Peg-Cutting Machine.

The shoe is advanced the proper distance to drive each nail, by a swing-plate *c*, whose foot is alternately lifted in and out of contact therewith, and is held at the moment of driving by the foot of the peg-tube.

Fig. 3606.



Sargent's Pegging-Machine.

The shoe is fixed on a jack mechanism consisting of: (1) a supporting upright *d* pivoted to the end of a weighted lever, and is so swiveled as to admit of movement both laterally and vertically; (2) jack-holder *e* joined to the upright by a pin *f*, its vibratory movement on the upright being restrained by stops so as to limit the tipping of the last. A spindle *g* projects from the holder on which the jack is mounted, and is supported on a socket piece, allowing free rotary movement of the jack on the spindle; (3) a last-holder *h*, supported directly over the spindle by a screw, and having a curved arm *i* to which the arm *k* carrying the heel-pin is jointed. It has a ratchet and pawl for forcing the last against the toe-piece *l*.

Digitized by Google

The arm *i* forms a handle by which the operator guides the shoe being pegged, and another handle operated by the other hand has connections which cause the pin *m* to engage a slot in the lip *n*, and serves to lock the shoe in stationary position relatively to the socket-piece, so that the efforts of the operator may be wholly directed to guiding the shoe without expenditure of strength to keep it in position.

Peg'ging-ram'mer. (*Founding.*) A pointed rammer for packing the sand in molding.

Peg-lad'der. A ladder with but one standard, into or through which cross-pieces are inserted. It is usually fixed.

Peg-strip. A ribbon of wood whose grain runs across the strip, and having one end sharpened, so that chisel-edged pegs may be split therefrom in the pegging-machine. The strip is coiled, placed in the machine, and the end fed into the guide. Invented by Sturtevant, 1858. See PEGGING-MACHINE.

Pein. The small end of a hammer. See PEEN.

Pei-ram'e-ter. An instrument invented by Macneil to indicate the amount of resistance offered by the surfaces of roads. It is a clumsy form of dynamometer, being dragged along on the ground. The power required to move it is indicated by a finger on a dial.

Pel'ham-bit. A bit having a flat, direct-acting joint and cheek-pieces, with bridle-rings at the mouth-piece, and a ring or loop upon the upper arm of the cheek and a loose ring on the lower one. It can be used as a curb or for a double cheek-bridle. This name is also given to bits having loose-jointed and port mouths with straight or crooked cheeks.

Pel'i-can. (*Ordnance.*) An old 6-pounder culverin.

Pel'le-tan-jet. An annular jet of steam used as a form of pump to induce a flow of liquid in an opening within or around the said issuing jet. It differs in principle in no substantial respect from the GIFFARD INJECTOR (which see). See also STEAM-JET; ASPIRATOR; EJECTOR.

Pe-lo'pi-um. Symbol, *Pe.* A rare metal.

Pelt. 1. The undressed skin of a beast with the hair on. They may be large or small, but are usually (not always) intended for furs or felting. *Peltry.*

Buffalo, wolf, gray fox, etc., are for robes.

Mink, otter, lynx, marten, sable, black fox, etc., are for wearing furs.

Musk-rat, coypu, beaver, musquash, hare, rabbit, and others, for the fine hair nearest the hide, for the purpose of felting.

Sheepskins with the wool on are also called pelts. When the hair is removed they become mere *skins.* As *tanned pelts* they form mats.

Fig 3607.

Pelvimeter.

2. The ball-leather used in making inking-pads.

Pel-vim'e-ter. (*Surgical.*) An instrument to measure the diameter of the pelvis, principally in the fore-and-aft direction.

The calipers of Bandelocque have blunt extremities, which are placed respectively on the symphysis pubis and the sacrum, about three inches being deducted for the thickness of the mons veneris, pubis, and the base of the sacrum.

Coutouly's instrument is like a shoemaker's foot-measurer, having a sliding lug. It is introduced into the vagina and then separated, so that one projection touches the promontory of the sacrum and the other comes behind the os pubis.

The cut represents King's pelvimeter with feelers half opened. It is introduced into the vagina with the piston drawn back. When in position it is pushed gently forward, which makes the feelers in front diverge, the extent of which is indicated on the piston-rod.

Pel'y-com'e-ter. A PELVIMETER (which see).

Pen. 1. Pens, if the term be held to include all writing instruments, are of two general kinds, those which scratch and those which use an ink. The former are the more ancient, and consisted of a stylus or bodkin made of bone or metal, and employed upon a leaf, a waxed tablet, a sheet of lead, a stone slab, etc.

The instrument by which an ink or pigment is applied consists of a pen or a brush. The pen was made forty centuries since of a reed (*calamus*), which held almost undisputed sway till the sixth century A. D., when the quill (*penna*) came into use. The materials on which the pen was used were bark, leaves (especially palm), linen, papyrus, skins, parchment, and eventually paper.

Job, chap. xix., seems to refer to the above-cited modes of writing. It is rendered in our version: —

"Printed [inscribed] in a book."
"Graven with an iron pen and lead."

Pliny remarks: "At first men wrote upon palm-leaves and afterward on the bark or rind of trees." The Latin words *volumen*, a scroll, *folio*, a leaf, *liber*, the inner bark, a book, are preserved in our language, indicating the form and the character of the material on which the writings of our distant predecessors were executed.

Writing on pieces of palm-leaves was a very ancient practice, and the Cingalese retain it to the present day. Oblong pieces are cut from the large leaf of the tree, and, being made of a uniform size, are neatly strung together with a cord. Many museums and libraries contain Hindoo, Burmese, and Cingalese books of this kind. The mode of writing upon these leaves was by a sharp instrument, a *stylus.* The point scratched through the external cellular matter, which shrank away from the incision, leaving a shallow groove which was made more plain by rubbing a black pigment into the lines so made.

We learn from Pausanias, a Greek topographical writer who flourished in the second century of our era, that the "Works and Days" of Hesiod, inscribed on *leaden plates*, were preserved at the fountain of Helicon in Bœotia down to his time, but were partly obliterated by the effects of wear and time. Hesiod lived about 900 B. C., but how long the plates had been engraved is another matter. Pliny mentions sheets of *lead* and *tablets*, and refers to their use in the remote past.

The Romans also used ivory tablets named *libri eborei* or *libri elephantini*, and Ulpian states that the transactions of the great were usually in a black color on ivory.

A number of engraved bronze tablets of Rome and Carthage are now in the British Museum. Eight bronze tablets were found in a subterraneous cabinet at Gubbio, Italy, in 1444. Seven of them bore inscriptions in Latin and one in Etruscan. The civil, criminal, and ceremonial laws of the Greeks were engraved on bronze tables. The speech of Claudius, on the same alloy, is preserved in the town hall of Lyons, France. The pacts between the Romans, Spartans, and Jews were written on brass. In many cabinets in Europe are discharges of Roman soldiers

Digitized by Google

written on copper plates. The laws of the twelve tables at Rome were inscribed on oaken boards; then transcribed on ivory tablets and hung up *pro rostris*, that they might be read by the whole people; after approval, they were permanently engraved on bronze and deposited in the Capitol, where a large collection was melted upon the occasion of the conflagration occasioned by that edifice being struck by lightning.

The Cretans also used bronze records.

Among the ancient inscriptions on bronze yet extant are the "Scriptum de Bacchanalibus," Imperial Library; Trajan's "Tabula Alimentaria"; the helmet found at Cannæ with Punic letters, in the museum at Florence, and various others in the Italian museums, containing inscriptions in Etruscan and Latin.

A deed for land, engraved on copper in Sanscrit characters and bearing date about 100 B. C., was dug up at Mongheer in Bengal. The grantor was a Bideram Gunt.

Pliny informs us that such documents were rolled up like a cylinder. Two letters are still preserved which passed between Pope Leo III. and Luitbrand, king of the Longobards. Montfaucon notices an ancient book composed of eight leaves of lead, the outside two forming the cover, and the whole held together by a leaden rod passing through rings at the back of the plates. The book contained mysterious figures of the Basilideans, together with words in the Greek and Etruscan characters.

The writing of the ancient Assyrians was impressed by knives or stamps upon cylinders or prisms of soft clay very carefully compounded and shaped. Some of these are rough, others polished or glazed. The writing is the cuneiform, the letters one eighth of an inch long.

The cylinders of carnelian, chalcedony, etc., were engraved seals by which the terra-cotta records were verified. See SEAL.

The use of wooden tablets covered with wax is closely allied to that of sheet-lead and a pointed stylus, but the product is of a more ephemeral character. The practice was very common in business and friendly correspondence, and also in official matters which did not require to be laid up for record. Such, for instance, is believed to have been the tablet presented by the Roman legate Popilius to Antiochus Epiphanes, ordering him to evacuate Egypt, which he did, as prophesied by Daniel 366 years previously (Daniel xi. 29, 30).

"Make it plain upon tables, that he may run who readeth it" (Habakkuk ii. 2). An allusion to the old system of relay couriers. Not "that he who runs may read," as often said.

The tables referred to by Isaiah and Habakkuk may have been of wood. The civil laws of Solon were recorded on wood, and placed in a machine constructed to turn easily, and called *axones;* such boards were called by the Greeks *schedæ* or *schedulæ;* when covered with wax, *pugillares cerei*. Pliny and other writers refer to the custom. When a number of such boards constituted a series of leaves, they were described as *cera prima, cera secunda, tertia*, etc. *Tabulæ* and *ceræ* are terms used by the ancient jurists as describing written statements and records. See also BOOK.

The reporters who wrote down the speeches in the forum preferred writing on waxed tablets, which required but a scratch of the stylus. No speed could have been effected with a brush and paint in following the Roman orators.

In the Abbott collection of Egyptian antiquities, now in the possession of the New York Historical Society, are a number of these tablets, made like our school slates and used for the same purpose. The middle portion was sunken to protect the writing, which was executed by a sharp bronze stylus upon a coating of black wax spread over the depressed surface. The latter was on both sides like our slates. The specimens were obtained from Abouseer, along with tee-to-tums, dolls, toys, and other evidences that the amusements of the children in the times of the Pharaohs were much like the modern.

Two ancient waxen tablets were discovered a few years since in gold-mines near and in Abrudbánya, in Transylvania. Each consisted of three tablets with raised margins (like a school slate) to protect the wax surface. The sections folded on each other; the middle one had two waxen surfaces; the outer ones but one each, on the inside. The Latin writing on one set of tablets was still visible, and was a copy of a document whose date determined it to be of A. D. 169. The inscription on the inner tablet was in Greek and nearly illegible.

For important purposes, such tablets were carefully inscribed and fastened consecutively by a cord; or for letters, the boards were covered with a linen cloth. In Hanover and Geneva schedules of this kind are yet preserved.

Leaves were also very generally employed in the early stages of society, and with some previous preparation are still in common use in the East.

In the University of Gottingen is still preserved a Bible containing 5,376 pieces of leaf, formed into 45 sheets. A large number of such books, principally Asiatic, are found in various museums.

The Syracusians and Athenians used olive-leaves for writing sentences of banishment upon, — a mode of punishment inflicted upon public men under a cloud in those turbulent republics.

The Balinese, the inhabitants of Bali, an island of the Malay Archipelago, write with a steel point on the *lanter*-leaf.

The sacred books of the Brahmins and Buddhists are written on leaves of the talipát palm (*talipoin*, a priest), which is a mammoth variety, growing as much as 200 feet high and 4 feet in diameter. The sacred fans of the Buddhists are made of its leaves. It lives to the age of a century and blossoms but once. The bloom is thirty feet in length, and at maturity explodes and scatters its seed.

Sir Hans Sloane's museum had more than 20 manuscripts of palm-leaves written in different Asiatic languages.

To leaves succeeded the *liber*, or inner bark of trees; this was united together so as to form a continuous roll, *volumen*, upon which the matter was written.

Skins of animals, parchment, fish-skins, and bones have been used, as existing specimens testify.

Puricelli mentions a grant by the Italian kings Hugo and Lotharis to the Ambrosian church of Milan written on the skin of a fish.

In the history of Mahomet it is recorded that his disciples wrote parts of the Koran on the shoulder-blades of sheep, which they strung together. Arab poetry was not unfrequently inscribed on these *scapulæ*, probably trimmed for the purpose.

The Alexandrian Library contained the works of Homer written in golden letters on the skins of animals; and the Iliad and Odyssey, written in golden letters on the entrails of animals, collectively 120 feet long, were extant at Constantinople in the reign of the Emperor Basileus. Other instances are known of the use of entrails for this purpose.

Before papyrus became common, the Ionians used instead the skins of sheep and goats, "on which material," says Herodotus, "the barbarians are even now wont to write." Ctesias says he obtained the matter for his Persian history "from the royal parchments" or skins. The invention of parchment is, however, ascribed to Eumenes, king of Pergamos, about 200 B. C.

For notices of papyrus and parchment, see PAPER.

Digitized by Google

The former instances particularly concern the use of the stylus. That of the *pen* proper will now claim our attention, after we have stated that the *brush* has been used for many centuries in Eastern Asia, and still holds its career of usefulness in forming the Chinese and Japanese letters. It has even been suggested that the brush preceded the pen, as the picture or ideographic writing preceded the phonographic; the language of symbols, that of arbitrary signs denoting sounds.

Fig 3608.

Japanese Scribe.

The characters of some written languages are well adapted for the brush, and the skill displayed by Chinese and Japanese gentlemen is curious and pleasing to us their neighbors, "upon whom the ends of the world are come," in a sense, for we meet directly by a reverse course the ultimate Orient of our predecessors, ourselves occupying the median line between the new civilizations of Greece, Rome, and their derivatives, and the far older and, to us, fantastic forms of Cathay and the lands thereto adjacent.

Fig. 3609 has two views from paintings at Thebes. The upper figure represents a scribe taking an account of the stock of an estate. It is a part of a much larger picture, in which the shepherds and groups of animals are shown. The scribe is writing upon a tablet; before him are two cases for carrying writing-materials. On his left is the inkstand with black and red ink.

Fig. 3609.

Egyptian Scribes (Thebes).

The lower figure shows a scribe with his inkstand upon the table. One pen is behind his ear, and he is writing with another.

The illustrative history of the Egyptians does not point to a time before the *reed* was used as a *pen*. The various paintings, palatial and sepulchral, show the scribes at work in their avocations, taking the tale of the hands and ears of slaughtered enemies, the numbers of the captives, the baskets of wheat, the numbers of the animals, the tribute, the treaties and public records.

The Egyptian pen of the time of Joseph was a reed, and the scribes used red and black inks, contained in different receptacles in a desk. When this Hebrew viceroy had a small army of clerks and store-keepers employed throughout Egypt in his extensive grain business, his scribes carried their writing-implements in boxes with pendent leather tops, and with handles at the sides. As the scribe had two colors of ink, he needed two pens, and we see him on the monuments of Thebes, busy with one pen at work, and the other placed in that most ancient pen-rack, behind the ear. Such is represented in a painting at Beni Hassan.

It is said that the best reeds for the purpose formerly grew near Memphis, on the Nile; near Cnidus of Caria, in Asia Minor; in Armenia and in Italy: those of the latter being of relatively poor quality. A place yet famous for them, and which may have supplied the ancient demand in part, is in the vicinity of the Persian Gulf, "in a large fen or tract of soggy land supplied with water by the river Helle, a place of Arabia formed by united arms of the Euphrates and Tigris. They are cut in March, tied in bundles, laid six months in a manure-heap, where they assume a beautiful color, mottled yellow and black." (CHARDIN.) Tournefort saw them growing in the neighborhood of Teflis in Georgia. Miller describes the cane as "growing no higher than a man, the stem three or four lines in thickness, and solid from one knot to another, excepting the central white pith." The incipient fermentation in the manure-heap dries up the pith and hardens the cane. The pens are about the size of the largest swan's quills. They are cut and slit like our pens, but have much longer nibs.

A little bundle of ancient pens from Egypt, with the stains of the ink yet upon them, may be seen in the museum of the Historical Society of New York, corner of Second Avenue and Eighth Street. Beside them is a bronze knife used in making the pens. In the East, the reed is yet the ordinary implement for writing.

"When he had finished, he dried the *bamboo-pen* on his hair, and replaced it behind his ear, saying, '*Yak posé*' (That is well). '*Témou èhu*' (Rest in peace), we replied; and, after politely putting out our tongues, withdrew." — *Abbé Huc at Lha-Ssa.*

The Christian monks of the land once known as Assyria still use a reed for writing the Chaldean character; the ink has a fine glossy character, the paper resembles parchment, and the scribes dispense with a table or desk, resting the paper on the knee.

Reeds are still used by the Arabs; their ink is thick and gummy. Reed pens are also found in Herculaneum. The ancient ink was of a viscid nature; some of it was found in a closed glass bottle in the examination of the city just mentioned.

The quills of birds came into use as pens in the sixth century A. D.; so we learn from Isidore (died A. D. 636) and others. Previous to this time, the writing-implement is spoken of as *calamus*, a reed; after this we read of *penna*, a feather: the reed, however, was a favorite in many quarters among the literati of Europe for five centuries after the first introduction of the quill. In an illuminated manuscript of the Gospels, executed in the ninth century, the evangelists are represented with quills in their hands. The quills of the swan, goose, eagle, owl, and hawk were used. The preference soon settled on those of the goose for obvious reasons, size and accessibility.

In the sixth century the quill-pen is also mentioned by Aldhelmus, a Saxon poet, who wrote a Latin poem entitled "De Penna Scriptoria."

But a century or so afterward paper was introduced into Europe by the Saracens; first as a curiosity, known as *Charta Damascena*, afterward manufactured in Spain and in Constantinople. See PAPER.

The list of devices by which characters were legibly portrayed by a scratching implement may be thus recapitulated: —

Digitized by Google

The *tabula* or wooden board smeared with wax, upon which a letter was written by a stylus.
The Athenian scratched his vote upon a shell, as did the lout when he voted to ostracize Aristides.
The records of Nineveh were inscribed upon tablets of clay, which were then baked.
The laws of Rome were engraved on brass and laid up in the Capitol.
The decalogue was *graven* upon the tables of stone.
The Egyptians used papyrus and granite.
The Burmese, tablets of ivory and leaves.
Pliny mentions sheets of lead, books of linen, and waxed tablets of wood.
The Hebrews used linen and skins.
The Persians, Mexicans, and North American Indians used skins.
The Greeks, prepared skins, called *membrana*.
The people of Pergamus, parchment and vellum.
The Hindoos, palm-leaves.

The first attempt at recording was probably what is termed picture-writing. This combines pantomime and numeration, and is found among many savage nations. Instances might be cited from Schoolcraft and from Catlin, and one remarkable example is given from the works of the latter author.

Fig. 3610 shows the robe of Mah-to-toh-pa, the head chief of the Mandans, which consisted of the skin of a young buffalo bull with the fur on one side and the battles of his life emblazoned on the other, by his own hand. It is shown in Catlin's

Fig. 3610.

Robe of Mah-to-toh-pa (Four Bears).

work on the "North American Indians," Vol I. p. 148, and is a good specimen of picture-writing.

It has twelve battle-scenes, showing various fights with Sioux, Riccarees, Cheyennes, and others.

The Egyptian temples and tombs abound with pictures too conventional to be artistic, but so admirably executed that they are bright and sharp even now. The peculiar atmosphere of the country has had something to do with their singularly perfect preservation. Three different forms of writing were used in that wonderful country, — the hieroglyphic, hieratic, and the demotic or enchorial. The first was probably the direct growth of picture-writing, but the characters had attained a certain arbitrary value at the time when the earliest yet existing records were made.

After what we may assume to have been the lapse of many ages, when the phonetic principle was introduced, an alphabet was framed, in which the sound of the first letter of the name of each object was represented by the object, as A by an eagle (*akkem*), M by an owl (*moulag*), etc. The Phœnician alphabet was similarly founded: A, *aleph* (a bull): B, *beth* (a house); G, *ghimel* (a camel), etc. These representations, in the earlier periods of their use, may have been executed with such skill as the artist had at command, and varied according to the talent and taste of the limner; but they afterward became conventional, variations were suppressed, and the portraits of the objects became simmered down to mere symbols.

In Fig. 3611, *a* is a view of a glass bead found by Captain Henvey, R. N., at Thebes. The drawing shows it about two thirds the real size; the inscription is developed on the right, and contains the name in hieroglyphics of a monarch who reigned about 1500 B. C.

b, Fig. 3611, is a remnant of the ages in the shape of a song. It was discovered by Champollion in a tomb at Eilethyas, and is interpreted by him as follows. It reads from right to left, and at the end of the first and third lines occurs the *dacapo* sign, to repeat the line: —

"Thrash for yourselves
Thrash for yourselves
O, oxen!
Thrash for yourselves
Thrash for yourselves
Measure for yourselves
Measure for your masters."

The most enduring of all records is the third in Job's recitation of the modes of writing which may be rendered: —

Written on leaves.
Marked with an iron pen on lead.
Cut into the rock forever.

For many centuries travelers have looked with amazement upon the sculptured buildings of Egypt, Nineveh, Phœnicia, and Persepolis, and upon the inscribed rocks of Behistan, on the frontiers of Media, and the precipice of Van, in Armenia. The solitary monument of Cyrus in the Murghâb, the records of Babylon and Nineveh, of the caves of India, the monuments of Lycia, the tombs of Etruria, the truncated pyramids and portals of Palenque and Uamal in Yucatan, and the broken tablets of Umbria and Samnium, all present riddles of more or less complexity to the students of language.

The setting up of memorial stones was the usual mode of celebrating an achievement or witnessing a pact. Two rival tribes or families set up an altar or build a pile of stones to determine the mutual boundaries of their pastures. A successful warrior made a memorial of his victory in the same manner. The warlike Osymandyas or Sesostris recorded the memory of his marches and exploits. The obelisks of Heliopolis rise to celebrate the return of manly vigor to the convalescent king. Phallic monoliths over the Nile land decently perpetuate the symbols of their religion, and are inscribed with the names and deeds of those who erected them.

Famous in olden times of these lithic monuments are the pillars erected by the children of Seth, as recorded by Josephus, and those erected by the Phœnician Hercules in the environs of Cadiz, monuments of his expedition into Spain. In the time of Demosthenes there was still remaining a column of stone on which the code of laws was engraved. The decalogue was carried in the ark for forty years, and thereafter remained for several centuries in various places, till it was placed in the temple of Solomon. The stones were thence carried as trophies to Babylon.

Engraved gems of the times of the Pharaohs are found among the ruins of the past, and the breastplate of Aaron had twelve stones engraved with the names of the tribes.

The mania for engraving on stones and setting up inscriptions in the wilderness is not dead yet. Missionaries start from the Lama monasteries, year after year, "chisel and hammer in hand, and traverse field, mountain, and desert, to engrave the sacred formula, *Om mané padmé houm*, on the stones and rocks they encounter in their path." They thus carve in Thibetan, Landza, or Tartar characters a prayer of the ages, the yearning of their great religious teacher, Sakya Muni, known as Buddha, the Enlightened, who raised his protest against Brahmanic intolerance on the plains of Nepal some twenty-four centuries since. The formula is from the Sanscrit, which had ceased to be a spoken language in the time of Alexander of Macedon. Its metaphor has been diligently resolved by Klaproth, and, being rendered into English, it means, *O that I may attain perfection and be absorbed in Buddha! Amen.*

The invading hosts of the Chaldeans left their pictured records on the rocks of Dog River, the ancient Lycus, in Palestine, which here impinges against one of the lofty and abrupt spurs of the mountains of Lebanon. These figures of men are ascribed to the time of Sesostris, and are associated with more recent inscriptions in Persian, Greek, Latin, and Arabic, indicating the presence of the various conquering races by which that country has been suc-

Ancient Writing.

d, Fig. 3611 (which is said by Du Halde to have developed into orderly characters by 2300 B. C., which is before the time of Abraham); and the most ancient Babylonian, *e*, which Sir Henry Rawlinson calls the Scythic or Accad alphabet. The other variant of the symbolic consisted of cursive expressions of the signs which stood for simple sounds, as stated above of the hieratic Egyptian.

The Scythic is among the earliest known of the *cuneiform*, so called from the resemblance of their

arrow-heads. It prevailed in the [illegible] watered by the Euphrates and Tigris, from the earliest historic period down to the conquest by Alexander.

The cuneiform evidently sprang from picture-writing, pictorial representations of objects being made to stand for certain words, eventually without regard to their original ideal signification. From this arbitrary but convenient arrangement came the still farther division by which characters were selected to form a syllabic system, a fixed sign being employed for each connection of a consonant with one of the vowels. There were many hundreds of these signs, representing the consonant and vowel combinations. A phrase is represented at *f*. The varieties of the cuneiform illustrate the progress of the ideographic to the syllabic; the Assyro-Babylonian is principally ideographic, as at *e*; fewer of these signs are in the cuneiform of the second period (*f*), and its derivative the Armenian; the Persian cuneiform is substantially syllabic. The Hebrew and other languages destitute of vowel indications, as they long were, were practically syllabic.

The cuneiform inscriptions of the Persian monarchs have been resolved by the skill and persistence of Grotefend, Burnouf, Rawlinson, and others. At first they seemed to modern eyes "a mere conglomerate of wedges, engraved or impressed." We have now several translations, editions, grammars, and dictionaries of these inscriptions.

The cuneiform writing runs from left to right.

g, Fig. 3611, shows the *hieroglyphic*, *hieratic*, and Phœnician characters representing the sounds D, R, L, N, SH, respectively. The reading is from the right to the left. Points of similarity and relationship are at once apparent. Some of them are fair illustrations of the statement that conventional elisions and modifications have taken place, until the mutilated figure is changed from a portrait to a symbol.

The *hieratic* writing is a short-hand pictorial script, in which the figures are somewhat disguised, and is the basis of true alphabetic writing, in which signs stand for vocal elements.

h, Fig. 3612, is a portion of the inscription on the Moabite stone. This is the oldest Semitic lapidary record of importance yet discovered.

In the summer of 1868, Mr. F. A. Klein, an agent of the Church Missionary Society, made a journey to Kerak, over a country seldom visited by Europeans. On his arrival at Dibân, the ancient Dibon, he was informed by Sheikh Zattam that, scarcely ten minutes from their tent, there was a black basalt stone with an inscription on it. This stone he soon found; it was 3 feet 5 inches high, 1 foot 9 inches wide, had thirty-four straight lines of writing about an inch and a quarter apart, and was rounded to nearly a semicircle at the top and bottom. Mr. Klein took a sketch of a few lines, and went his way, determined if possible to get it removed to the Berlin Museum.

M. Ganneau obtained a few squeezes of the face of the stone before it was broken up by the Arabs, who discovered that it had a market value; strange to say. They made a fire under it and then poured water on it, the villains.

Herr Nöldeke says: "It is *the most ancient memorial of pure alphabetical writing*, much older than any in the Greek. It is the only *original document on the history of Israel* before the time of the Maccabees, and throws light on the relations of Israel with a neighbor much spoken of in the Old Testament."

Until the discovery of this stone, the sarcophagus of Eshmunazar (about 600 B. C.) was considered the most ancient inscription of any length. Here we have a long specimen of the earliest Phœnician character, — the alphabet from which the Greek, the Roman, and all our European alphabets are derived. As Count de Vogué says, these are the very characters which, before 700 B. C., were common to all the races of Western Asia, from Egypt to the foot of the Taurus, and from the Mediterranean to Nineveh; which were used in Nineveh itself, in Phœnicia, Jerusalem, Samaria, the land of Moab, Cilicia, and Cyprus. It disproves the assertion of Aristotle and Pliny that Cadmus only brought 16 or 18 letters from the East into Greece, and that the Greeks invented the rest, for the whole of the 22 are found on this monumental stone.

The Rosetta stone is of 700 years later date. It was found in 1798 by a French engineer in digging the foundations for a fort near the Rosetta mouth of the Nile. It is a tablet of basalt, with an inscription of the year 196 B. C., during the reign of Ptolemy Epiphanes. The inscription is in hieroglyphic, demotic, and Greek.

It was deciphered by Dr. Young, and formed the

key to the reading of the hieroglyphic characters. It was captured by the English on the defeat of the French forces in Egypt, and is now in the British Museum.

The hatchet, mallet, chisel, square, and saw, all occur among the hieroglyphic characters. *i*, Fig. 3612, shows small portions of the hieroglyphic and demotic inscriptions, respectively.

The "Canopus" stone has since added to the fund of knowledge on the subject, and has afforded additional means and subjects for comparison.

"It was through the commercial intercourse of the Ionians with the Phœnicians that the Greeks received the characters of their alphabetical writing, which were long termed Phœnician signs. According to the views which, since Champollion's great discovery, have prevailed more and more respecting the early conditions of the development of alphabetical writing, the Phœnician and all the Semitic written characters, though they may have been originally formed from pictorial writing, are to be regarded as a *phonetic alphabet*, i. e. as an alphabet in which the ideal signification of the pictured signs is wholly disregarded, and these signs or characters are treated exclusively as signs of

sound. Such a phonetic alphabet, being in its nature and fundamental form a syllabic alphabet, was suited to satisfy all the requirements of a graphical representation of the phonetic system of a language." — HUMBOLDT.

"Phœnicia, mother of the arts,
Letters to learned men imparts."
CRITIAS, *quoted by* ATHENÆUS (A. D. 220).

The ancient Pelasgic, assumed to be the immediate parent of the Greek, was written from right to left, like the Phœnician, whence it came. *j*, Fig. 3613, is an inscription, [Τι]-*μων ἐγραφέ με.* The letters are Phœnician, as used in early times in Greece. It was found in the island of Thera.

Pelasgic and Boustrophedon Greek.

k, Fig. 3613, is an illustration of the writing *boustrophedon* (as oxen plow), right to left and left to right alternately, *χρήσιμος — σωμισήρχ*. It is from the temple of Bedesish, Egypt.

Plate XXXIX. represents the passage, "*God hath made of one blood all nations of men*," in one hundred and three languages.

Fig. 3614 shows the same passage in six Asiatic languages. The first of these is written from left to right, the other five from right to left.

Chinese and Japanese Writing.

The Hebrew Scriptures were written upon the skins of ceremonially clean animals or even birds. These were rolled upon sticks and fastened with a cord, the ends of which were sealed when security was an object. They were written in columns, and usually upon one side only. The writing was from right to left; the upper margin was three fingers broad, the lower one four fingers; a breadth of two fingers separated the columns. The columns ran across the width of the sheet, the rolled ends of which were held vertically in the respective hands. When one column was read, another was exposed to view by unrolling it from the end in the left hand, while the former was hidden from view by rolling up the end grasped by the right hand. The pen was a reed, the ink black, carried in a bottle suspended from the girdle.

The Samaritan Pentateuch is very ancient, as is proved by the criticisms of Talmudic writers. A copy of it was acquired in 1616 by Pietro della Valle, one of the first discoverers of the cuneiform inscriptions. It was thus introduced to the notice of Europe. It is claimed by the Samaritans of Nâblus that their copy was written by Abisha, the great-grandson of Aaron, in the thirteenth year of the settlement of the land of Canaan by the Children of Israel. The copies of it brought to Europe are all written in black ink on vellum or cotton paper, and vary from 12mo to folio. The scroll used by the Samaritans is written in gold letters. (See Smith's "Dictionary of the Bible." Vol. III. pp. 1106–1118.) Its claims to great antiquity are not admitted by scholars.

Previous to the tenth century, the manuscripts were written in capital letters, and without a space between the words. The three most important and valuable of them are the Sinaitic, the Vatican, and the Alexandrian, many of whose various readings are given by Tischendorf in his Leipsic edition of the English New Testament. The Sinaitic manuscript, critically marked *Aleph*, written on parchment, was discovered by Tischendorf, February 4, 1859, in the convent of St. Catharine, on Mount Sinai, in Arabia, and published by him in fac-simile in 1862, and in the common type in 1865. It contains the entire New Testament, and is deposited in the Imperial Library at St. Petersburg. It was printed in Leipsic for the Emperor of Russia, to be a memorial of the thousandth anniversary of his king-

dom. It is in uncial characters, apparently of the fourth century. The Vatican manuscript, marked B, also written about the middle of the fourth century, has been published only since 1857. It is in the Vatican Library at Rome. The Alexandrian manuscript, marked A, written about the middle of the fifth century, was first published in 1786. It is in the British Museum, at London. The Ephraim or Royal Paris manuscript, marked C, of the fifth century, and the Cambridge manuscript, marked D, of the sixth century, are next in value. These marks are agreed upon by scholars to designate certain manuscripts.

The enumeration of some of the modes of writing may be interesting: —

The *Mexican* writing is in vertical columns, beginning at the bottom.

The *Chinese* and *Japanese* write in vertical columns, beginning (Fig. 3615) at the top and passing from left to right.

The *Egyptian* hieroglyphics are written in vertical columns or horizontal lines according to the shape and position of the tablet. It is said that with the horizontal writing the direction is indifferent, but that the figures of men and animals face the beginning of the line. With figures, the units stand on the left.

The Egyptians also wrote from right to left in the hieratic and the demotic or enchorial styles. The Pelasgians did the same (*j*, Fig. 3613), and were followed by the Etruscans. In the demotic character, Dr. Brugsch remarks that, though the general direction of the writing was usually from right to left, yet the individual letters were formed from left to right, as is evident from the unfinished ends of horizontal letters when the ink failed in the pen.

In writing numbers in the hieratic and enchorial the units were placed to the left. The Arabs write from right to left, but received their numerals from India, whence they call them "Hindee," and there the arrangement of their numerals is like our own, units to the right.

The Ethiopic and cuneiform characters (*c e*, Fig. 3611) are written from left to right like our own, and this is true of most of the Indo-European languages, while those of Semitic origin are written from right to left. The Phœnician alphabet, the reputed parent of this family, is so written, and the branches include the Chaldaic, Hebrew, Syriac, Carthaginian, Samaritan, Arabic, and Persian characters.

The Pelasgic tribes spoke a language of the Aryan family, allied to the Sanscrit, but obtained their letters from the Phœnicians, and long wrote them from right to left (*j*, Fig. 3613) as in the land from whence they were adopted. The Greek was afterward written *boustrophedon* (as oxen plow), right to left and left to right alternately (*k*, Fig. 3613); in allusion to the usual mode of plowing, before mold-boards and plowing in lands were invented, when the oxen returned close alongside the last furrow made. The laws of Solon were written *boustrophedon*. The later Greek, long before the Christian era, came to be written from left to right like the Sanscrit and the other languages to which it — not its characters — was allied.

The number of letters in the following alphabets is thus given in Ballhorn's "Grammatography," Trubner & Co., 1861: —

Hebrew	22	Ethiopic	202
Chaldaic	22	Chinese	214
Syriac	22	Japanese	73
Samaritan	22	Dutch	26
Phœnician	22	Spanish	27
Armenian	38	Irish	18
Arabic	28	Anglo-Saxon	25
Persian	32	Danish	28
Turkish	33	Gothic	25
Georgian	38	French	28
Coptic	32	German	26
Greek	24	Welch	40
Latin	25	Russian	35
Sanscrit	323		

The letter "J" was introduced into the alphabets by Giles Beye, a printer of Paris, 1660.

Short-hand writing was known to the Greeks and Romans. Its invention was ascribed to Xenophon. It was introduced into Rome by Cicero. Pliny employed a short-hand amanuensis.

The Chinese dictionary shows 43,496 words: of these 13,000 are irrelevant, and consist of signs which are ill-formed and obsolete. For ordinary use 4,000 signs suffice. Kung-fu-tze can be read with a knowledge of 2,500. There are 214 root-signs, so to speak, which indicate the pronunciation, and form *keys* or *radicals*, called by the Chinese *tribunals*. Each character is a word, and the actual number is vastly increased by tones which give quite a different value and meaning.

Quills for pens are assorted into qualities determined by the character of the barrel. They are plunged into heated sand to make the exterior skin peel off and the interior membrane shrivel up. This may be performed, however, by alternate soaking in water and drying before a charcoal fire. They are hardened by soaking in a hot solution of alum.

The yellow color so much admired is conferred upon the quill by a dip into nitric acid.

Iron pens are mentioned by Chamberlayne in 1685.

The first metallic pens regularly introduced for sale were by Wise, about 1803. They were made in *barrel* form, being adapted to slip on a stick, and under the name of *perpetual pen* were industriously distributed throughout the stationers' shops of London. The prejudice was strong against them, and up to 1835 or thereabouts quills maintained their full sway, and much later among people of a conservative cast of mind and in the circumlocution offices here and abroad.

The writer recollects the tedious waiting for the patient usher who passed from desk to desk with his pen-knife, mending pens and paying very little attention to anything else; also the wonder felt and expressed at the first sight of steel nibs, and how they dug into the paper.

Bramah patented *quill-nibs;* made by splitting quills and cutting the semicylinders into sections which were shaped into pens and adapted to be placed in a holder. These were, perhaps, the first *nibs*, the progenitors of a host of steel, gold, and other pens. See PEN-MAKER.

Hawkins and Mordan, in 1823, made nibs of *horn* and *tortoise-shell*, instead of quill. The tortoise-shell being softened, *points of ruby* and *diamond* were imbedded. Metallic points were also cemented to the shell nibs.

Doughty, about 1825, made *gold pens* with *ruby points*. See GOLD PEN.

Gold pens with *rhodium points* were introduced soon afterward.

Gillott devoted much pains to the improvement of the material and manufacture. One of his patents was in 1831. See STEEL PEN.

Perry exercised considerable ingenuity in the application of new forms and in developing the elasticity. His patents were in 1830 and 1832.

Mordan's *oblique pen*, English patent, 1831, was designed to present the nibs in the right direction while preserving what most people appear to think the most convenient position of the pen and the hand.

Scheffer's *fountain-pen* was introduced about 1835 by Mordan. The pressure of the thumb on a stud in the holder caused a continuous supply of ink to flow from the reservoir to the pen. See FOUNTAIN PEN.

Parker's *hydraulic pen* (English) has a piston which works up and down in a tube by means of a screw stem and a revolving nut on the end of the holder.

Fig. 3616 shows several forms of pens.

a is a pen with a broad flat nib made for marking packages, for writing placards and show-bills. Ink is retained between the several superposed plates, and the breadth of the nib determines the width of the stroke, unless the pen is turned edgewise.

b is a reservoir pen having fluted sides to lead the ink from the reservoir to the nib.

c is the iridium-tipped gold-nib pen, mounted with gutta-percha or hard rubber.

d has wings to hold a globule of ink.

e has a flexible strap around the nibs for the same purpose.

f has a peculiarly bent body to give elasticity and also form a holder for ink.

g has wire below the nib, to hold ink.

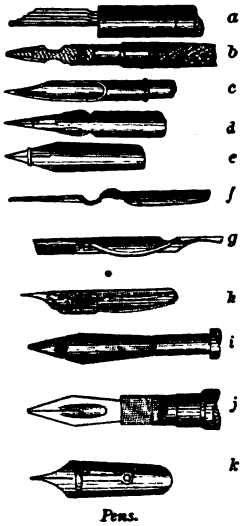
h has bent-over wings for the same purpose.

i has a wire likewise.

j, a depression in the body of the pen.

k, a cruciform piece riveted to the under side of the pen.

Fig. 3616.



Pens.

2. An ink-leg of a compass.

A draftsman's instrument for drawing lines of even thickness, or dotting lines. See DRAWING-PEN.

See GOLD PEN; STEEL PEN; FOUNTAIN-PEN; DRAWING-PEN; RULING-PEN; MUSIC-PEN; DOTTING-PEN, etc.

3. An inclosure of limited size for cattle or hogs.

Pen'chute. A trough conducting the water from the race to the water-wheel.

Pen'cil. 1. A cylinder or slip of marking material, usually graphite, but may be of colored crayon or French chalk. It is usually inclosed in a sheath of cedar, but is sometimes a cylinder or prism of sufficient size to be grasped by the fingers or by a porte-crayon.

The kind of pencils known as lead-pencils is made from *graphite*, otherwise known as *plumbago* or *black-lead*. The latter two names are misnomers, as no portion of lead enters into its composition. See GRAPHITE.

Graphite is a soft variety of carbon, sometimes containing a small proportion of iron. It is found in many parts of the world, but few localities yield it of sufficient purity for making pencils. For many years the best obtainable was from the mine of Borrowdale, Cumberland, England, discovered in 1564. It was locally known as *wad*. This mine gave England the monopoly of the finest quality of pencils, and the amount taken from the mines yearly was strictly limited in order to keep up the price. The annual product was valued at £40,000. This source of supply eventually failed, but the loss was scarcely felt, as a number of other mines had been discovered in various parts of the world.

The ancients drew lines and letters with leaden styles, and afterward an alloy of lead and tin was used. Pliny refers to the use of lead for ruling lines on papyrus. La Moine cites a document of 1387 ruled with graphite. Slips of graphite in wooden sticks (pencils) are mentioned by Gesner, Zurich, in 1565; he credits England with the production. They were doubtless the product of the Borrowdale mine, then lately discovered. In the early part of the seventeenth century, *black-lead* pencils are distinctly described by several writers. They are noticed by Ambrosinus, 1648; spoken of by Pettus, in 1683, as inclosed in fir or cedar.

Red and black chalk pencils were used in Germany in 1450; in fact, fragments of chalk, charcoal, and shaped sticks of colored minerals had been in use since times previous to all historic mention.

Painting of the body, face, and limbs is an accomplishment in all countries where clothing is scanty, and some tribes have ingeniously contrived to make it permanent by tattooing. This art is both ancient and modern, and has its professors in many countries. The name is Polynesian, and among these singular peoples the practice has been, perhaps, perfected. Vagabonds on the fringe of civilization emulate the rites of their ancestors, and naturally recur to the habit of tattooing; hence ships, hearts, true-lovers' knots, and mottoes pricked into the arms and breasts; and hence means of identification equal to the famous "strawberry-mark on the left arm" of the long-lost brother, or, equally famous now, the absence of the tattooed mark on the arm of the spurious Tichborne.

Hans Holbein drew portraits in crayon in 1540. Sir Thomas Lawrence excelled in crayon-drawing during the early part of the present century. Crayons and pencils are used by painters in designing and sketching-in on canvas. The imitation of the chalk-drawing has given rise to one style of plate-engraving, known as the *stipple* or *chalk* engraving.

When Cortez landed in Mexico in 1520, he found the Aztecs using graphite crayons, which were probably made from the mineral found in Sonora.

As has been said, the mounting of the small graphite bars in wood originated in England. The block of graphite was sawed into prisms of the required shape, and of such length as the lump admitted. Each slip of graphite was laid in a groove made in a slip of cedar, a little glue causing it to adhere; another slip of cedar was laid over it, and the pencil was shaped by a round-soled plane. Several lengths of graphite filling were required for the length of a pencil, as the lumps were usually small in size and the pieces very frangible.

To utilize the waste, Mr. Brockedon attempted to compress it into blocks in powerful hydraulic presses, but without much success. The plan of grinding up into a pigment, which was hardened into a block by baking, was afterward introduced with better result.

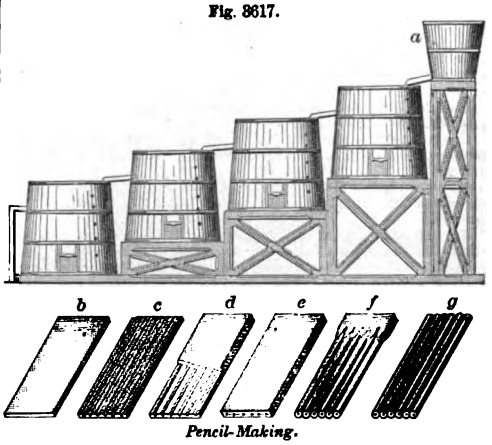
When the Borrowdale mine was giving out, Conté of Paris invented the method of producing the *leads* by making a mixture of graphite and clay, pressing it into the required shape from a mass like dough, and baking it to the requisite hardness for use. All the pencils now made in any part of the world are made by Conté's process.

The following is the method employed by Mr. Cleveland, of the Dixon Company, at Jersey City, in the production of "Dixon's American Graphite Pencils":—

The graphite is purified by various means, according to the nature of the foreign matter it may contain. Ticonderoga graphite ground fine in water is treated with sulphuric and nitric acids, and, after washing clean, heated to a bright red. See GRAPHITE.

It is then mixed with water until thin enough to run very freely, and the mixture turned slowly into the hopper (see *a*, Fig. 3617). The coarser or heavier particles will settle at the bottom of the

Fig. 3617.



Pencil-Making.

first tub, the next heavier in the next tub, and so on, till the water will run almost clear from the overflow of the last tub, as shown in the cut.

For the finest pencils the deposit in the last tub is used, but for the commoner sorts the deposit in the tub next to the last will answer very well, and for ordinary pencils the deposit in the one still before that is used. The stream should run into the first tub very slowly and gently, so that the contents of each tub will be but slightly disturbed.

When the operation has been going on for some time the inlet is stopped, and after leaving the tubs for half a day to settle, the clear water above the deposit is decanted by withdrawing a small pine plug, several of which are inserted in holes bored in the sides of the tubs, at convenient distances from the top, and by drawing out these one at a time as the water gets lower, all the water is decanted without disturbing the deposited graphite, which is very light and will rise with the least agitation, especially that which is deposited in the last tub.

Digitized by Google

The gates near the bottom of the tube, shown in the cut, are then raised and the contents removed and dried.

The graphite is now ready for the *clay*.

The clay this company employs is known in market as *pipe-clay*, of a bluish-gray color, has great strength, and is very unctuous and fatty when wet. It comes to this country from Rotterdam for the manufacture of crucibles. The clay is separated in water and floated through a series of tubs in the same manner as the graphite, only the finest part being fit for pencils.

Like the graphite, it is dried before mixing, in order that the mixture may be exact and reliable for the production of the different grades of *leads*. The larger the proportion of clay the harder the grade, and a less proportion of clay and more graphite produces a softer grade. For a medium grade the proper proportion is, 7 parts of clay to 10 parts of graphite, by weight.

Water is added to the clay and graphite, and the mass fairly mixed by the hands to the consistency of thick cream. In this state the mass is fed into the mills for final grinding. The mills are of stone, 24 inches in diameter, only the top stone running, and that at considerable speed. This operation is much like grinding paint, and the mass is passed through these mills many times; for the fine pencils it is ground over as many as twenty-four times before it is considered ready for use. It is now a pasty mass, and this is inclosed in a canvas bag and placed in a powerful steam-press, where the water is pressed out, much the same as oil is pressed out of ground linseed. This pressing is carried to that point that leaves the mixture a stiff dough, ready for the forming-press.

The forming-press is composed of a cast-iron well, 8 inches deep and 4 inches in diameter, inside measure, having a follower or plunger, like an old-fashioned sausage-stuffer. The material is molded into the shape of the inside of the well, by working it with the hands as the potter works his clay, placed in the well and driven snug down with a hammer and wooden plug; the iron follower then comes down slowly, driven by a powerful screw.

In the lower end of the well, which is upright, is an opening of the exact size and shape, square or round, desired for the leads; and as the follower presses upon the material, a thread spins out below and coils itself upon a board placed underneath to catch it. A sufficient quantity being spun out for convenient handling, the board is removed and another put in its place. From this coil the *lead* is drawn off and straightened out upon boards of suitable length for three pencils, the back edge of the board having a raised straight-edge against which the first length is placed, the next length laid snug against the first, and so on till the board is full, when it is placed carefully away for the leads to dry. When dry they are very brittle, and are cut into lengths for pencils, placed upright in crucibles of graphite, made for this use, with straight sides and fitted with covers.

When the crucible is full the leads are covered over with fine graphite to exclude the air, and as a farther precaution the cover of the crucible is well luted on. The crucibles are then heated to a red heat, taken out of the oven and cooled, and the leads removed ready for use.

The next step is the preparation of the wood. Only a soft, close-grained wood will answer, and the best is the Florida cedar.

The wood is sawed into pieces *b* of the right length for a pencil, of a width suitable for six, and of half the thickness for pencils.

These blocks run through a machine that planes and grooves them (*c*), the grooves being the depth of half the size of the leads. The leads are then laid into the grooves of one piece while the other piece of cedar exactly like it is coated with glue and laid on the first (*d*). These double pieces, or blocks, are then placed in a press, many of them together, till dry enough to proceed. Leaving the press they are solid blocks containing six leads equidistant from each other, ready to be shaped into six pencils, and these blocks (*e*, Fig. 3617) go through the first machine, that brings them to size, and then through the next machine, similar to a molding-cutter, coming out six pencils from each block. The cut *f* shows the block before it is quite through the machine; *g* shows six perfect pencils.

The machine which converts the block into pencils is of the nature of a planing-machine with a series of circular cutters above and below, like the molding-machines for wood-working. The effect of the upper and lower rows of cutters is, respectively, to cut a series of six beads, the joint effect being to make six cylinders from the block, the parts and positions of the cutters being so accurately gaged as to leave the *leads* in the exact center of each cylinder (or hexagon, as the case may be), and leave no fin or mark upon the edges of the pencils where the action of the upper and under series of cutters meets at the middle of each pencil, as shown in the cut.

The knives in these shaping-machines, in order to do the work well, should revolve at the rate of 4,500 revolutions per minute, and must run absolutely true, as any weakness or tremor will destroy the finish on the surface of the wood, and make it necessary to adopt the old process of sand-papering each pencil, as still practiced by other manufacturers. The finish obtained by the machine is such that sand-paper would roughen them. The round and hexagon or other shapes are produced in the same way. The pencils are now ready to receive the color and finish, according to taste, and are then stamped and packed for market. Great care must be taken to have the wood dry, and it is better air-dried than kiln-dried.

The machine for shaping turns out the pencils from the blocks at the rate of 72 per minute, or over 43,000 per day. The varnishing and coloring of the surface is done by a machine at the rate of 120 per minute, or 72,000 per day, and they are polished by a machine at the rate of 106 per minute, or over 63,000 per day. All of these machines are attended by girls about twelve years of age, one to each, no skilled labor being required.

The granular formation of graphite is more easily prepared than the foliated. The Dixon Company has extensive mines at Ticonderoga and a large mill at the outlet of Lake George into Lake Champlain, where the pure foliated graphite is manipulated very cheaply.

Colored pencils are made in the same way as black, except that the little bars cannot be baked like the black *leads*. Heating destroys the color.

In making them, coloring-matter of the kind desired is used with the clay, instead of graphite, and they are boiled in wax before being placed in the wood.

The Florida cedar is used by all of the principal pencil-makers in the world, on account of its fine grain, softness, and strength combined.

Dixon's American graphite pencils are in different styles, as *black*, *maroon*, *cedar-finish*, the latter being in the natural color of the cedar of which they are all made; *satin-finish*, a new style, is made of the same cedar, but finished to resemble French walnut in color, showing the grain of the wood. There are ten distinct grades of hardness in the leads, shown by the grade stamps, as follows: VVS, *very, very soft*, for the deepest heavy shading. VS, *very soft*, for very deep shading. S, *soft*, for rapid shading in sketching, the softest grade for office use. SM, *soft medium*, for general sketching, the popular grade for office or pocket. MB, *medium black*, for drawing or general use. M, *medium*, for office and stenographic, professional, or desk use. MH, *medium hard*, for finer desk use or fine lines in drawing. H, *hard*, for bank use, or finer lines in drawing. VH, *very hard*, for architects, engineers, draftsmen, etc. VVH, *very, very hard*, for the finest lines.

The S, SM, M, H, and VH are the five regular office grades. The whole ten grades are for artists. The SM and M only are made in the round black pencils with the gold stamp, and in the maroon finish both round and hexagon shapes. But the five regular office grades of leads are made in round and hexagon shapes, in both the *cedar finish* and the new *satin finish*, and the whole ten distinct grades of leads, for artists and technical uses, made of the hexagon shape only, both of these styles of finish.

The old method of sawing them out of solid blocks of graphite produced leads of rectangular shape, and the Dixon Company continued in that shape to the present day; but making a decided improvement. The round leads are more easily sharpened, are stronger than the flat shape, and more harmony with the exterior of the finished pencils.

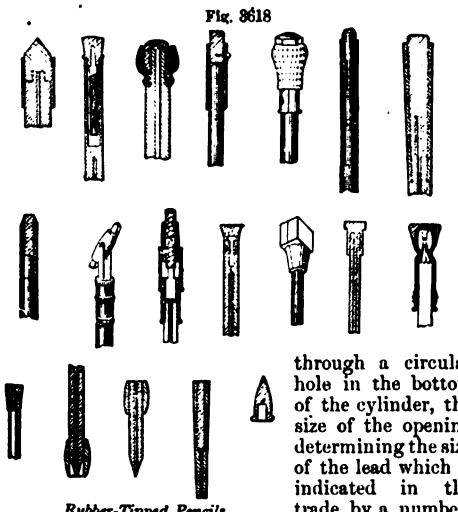
Fig. 3618 shows a number of modes of attaching rubber to lead-pencils.

Various convenient additions to pencils have been made, such as attaching calendars thereto, sheaths to cover the leads, thimbles and sockets to attach the pencil to the lappel of the coat or vest, a pencils in a pair of sheaths jointed together convenient pair of compasses for many purposes.

The *pencil-leads* as sold by stationers and used for pencil-cases and ever-point pencils are little cylinders made of graphite and clay kneaded with water until it assumes the consistency of putty. This is placed in a cylinder and forced by heavy pressure

Digitized by Google

Fig. 3618



Rubber-Tipped Pencils.

through a circular hole in the bottom of the cylinder, the size of the opening determining the size of the lead which is indicated in the trade by a number. The material issues in long flexible threads, which are received on sheets of metal and placed in an oven. The length of time occupied in the baking determines the hardness. The threads are then broken up into short pieces and boxed according to their sizes, Nos. 1 to 9.

2. A small brush or *tool* employed by painters. Pencils are made of camel, badger, squirrel, fitch, or sable hairs.

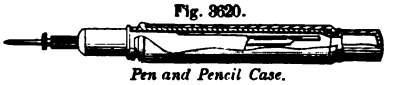
3. To draw a line of white paint along a mortar-joint in a brick wall, to render the joint more conspicuous and contrast with the color of the bricks. This is termed *penciling*.

Fig. 3619.

Pencil-Case.

Pen'cil-case. A holder for a pencil, usually with a slide by which the pencil is

Fig. 3620.



Pen and Pencil Case.

retracted into its sheath to reduce the length of the instrument and preserve the lead from breakage when carried in the pocket.

Fig. 3621.

Ever-point Pencil.

The usual form has a hollow holder from which the tube holding the pencil-lead is projected by twisting or by simply sliding out.

In Fig. 3620, the case consists of a single tube with a screw cap, and a reversible penholder and pencil-point. The tube has also a section extensible telescopically.

In Fig. 3619, the pen is on a sliding piece at one end, while the pencil-holder is socketed in the other end, either projecting for use or inclosed for compactness in carrying-ing.

The ever-point pencil was patented in England in 1823 by Hawkins and Mordan.

The small cylinder of black-lead is pushed forward by a driver, so as to project through the end of the nozzle. On the outside of the driver is a screw, and on the end of the lead-cylinder is a nut, so that when the nozzle is held in one hand while the case is turned by the other, the driver is worked in or out for the reception of another lead or for the driving out of the contained lead, respectively.

Pen'cil-clasp. A device to hold a pencil to the lappel or breast of the coat. Used by import clerks and others.

Pen'cil-com'pass. One having a pencil-end at one leg; or a compass to which an ordinary pencil may be attached, as in the example.

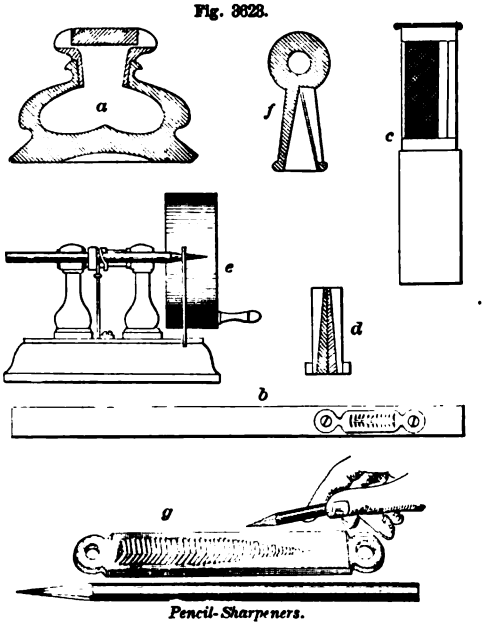
Fig. 3622.

Pencil-Compass.

Pen'cil-sharp'en-er. A device against which a lead or a slate pencil is drawn or rotated in order to sharpen the point.

For slate-pencils it may consist of a file on a stake, in a cup *a* or on the edge of a slate-frame *b*. The same may answer for lead-pencils if the wood be previously cut away. *c* is a pocket-file which slips into a sheath. *d* is a serrated socket in which the pencil-point is rotated. *e* is a form in which the pencil is held against a rotating wheel. *f* has a blade which will cut wood and lead impartially. *g* is of hardened steel, the groove being serrated.

Fig. 3623.



Pencil-Sharpeners.

Pen'dant. 1. (*Nautical.*) *a.* A strap or short rope depending from a mast-head, and having thimbles for bearing the blocks, which transmit the effects of tackles to distant points. Their names indicate their specific duty; as, *fish*-pendant, *brace*-pendant, *stay-tackle* pendant, etc. Used especially in setting up masts and rigging.

b. (Or *Pennant.*) A long, narrow strip of bunting worn at the mast-head of vessels of war. Playfully called a *coach-whip*, in contradistinction to a *broad pennant*. See PENNANT.

2. (*Architecture.*) *a.* An ornament suspended from the roof of a Gothic or Tudor building; the hanging ornament from the crown of a vaulted ceiling.

b. A hanging keystone, the lower face projecting beyond the intrados of the arch.

3. An ear-ring or bob.

4. The part of a watch by which it is suspended. Usually consisting of a guard-ring and pusher-pin.

5. A suspended chandelier.

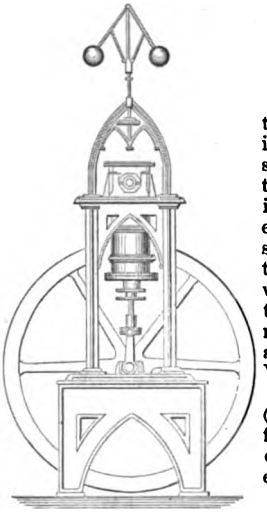
Pendant-Winding Watch.

pendant brought into gear with wheels connecting to the spring-arbor. In the example, the spring is wound and the hands set through the stem of the pendant; a single inflexible rod operates each mechanism. For setting, the stem is partially retracted, and the watch is wound by rotating the stem at its normal projection. See also STEM-WINDING WATCH.

Fig. 3627.



Pendulous-Cylinder Steam-Engine.

Pen-dent'ive. (*Architecture.*) *a.* The filling in of the spandrels between the arches of a vault.

b. Also between the arches under a dome.

c. The portion of a groined ceiling supported and bounded by the apex of the longitudinal and transverse vaults. In Gothic ceilings of this kind the ribs of the vaults descend from the apex to the impost of each pendentive, where they become united.

Pen'du-lous-cyl'in-der Steam-en'gine. A form of oscillating-cylinder steam-engine in which the cylinder is suspended so as to oscillate below its trunnions, as seen in the illustration. The valve may be a disk-valve in the trunnion or a slide-valve on the side.

Pen'du-lum. *a.* A heavy body so suspended as to vibrate about a fixed point by the action of gravity.

Pendulums in chronometry are known by structure or function; as, —

Compensation pendulum, having isochronous means within itself for adjustment, compensating the effects of heat and cold.

Conical pendulum, having a circular path, the rod of suspension describing a cone.

Cycloidal pendulum, vibrating in the arc of a cycloid instead of a circular arc.

Gridiron pendulum, having parallel bars of brass and steel, whose diverse expansion under heat is made to preserve uniformity of the center of oscillation of the bob.

The *mercurial* pendulum, having for a bob a vessel of mercury, whose upward expansion by heat so compensates the lengthening of the rod that the center of oscillation remains the same.

The *seconds* pendulum, vibrating 3,600 times in an hour.

b. A wheel oscillating on an axis, known as a *verge*, and determining by its isochronal pulsations the movement of the train.

c. Besides these are devices not chronometric, as the *hygrometric pendulum*, *ballistic pendulum*, etc.

Previous to the application of the pendulum, a fly-wheel was used, the vanes meeting the resistance of the air, forming a limit to the speed, as in the musical boxes of the present day.

Such was probably the regulator in the clocks of the Saracens, which were moved by weights as early as the eleventh century; the clock which struck the hours, referred to by Dante (1265–1321); the clock in the old Palace Yard, London, put up about 1288 and remaining till the time of Elizabeth; the clock made by William of Wallingford in the reign of Richard II. (1377–85).

Ebn Junis, of the University of Cordova, invented the time-measuring pendulum, and his friend and fellow-philosopher, Gerbert, invented the escapement, as it is believed. Gerbert became, successively, schoolmaster at Rheims (where he had a clock), Archbishop of Ravenna, and Pope Sylvester II. He died by poison in 1002. So did his patron, Otho III., about the same time.

An oscillating arm was substituted for the fly, probably in the fourteenth century.

The clock of Henry de Wyck, erected in 1364, for Charles V. of France, was regulated by an alternating balance (*a*, Fig 3628) which was formed by suspending two heavy weights from a horizontal bar fixed at right angles to an upright arbor, and the movement was accelerated or retarded by diminishing or increasing the distance of the weights from the arbor.

The clocks erected at Strasburg, 1370, Courtray, 1370, and Spire, 1395, were probably of this character, as were also the astronomical clocks of Tycho Brahe and other less celebrated astronomers of his period.

b shows the Harris pendulum as contrived by him in the clock put up in the turret of the Church of St. Paul, Covent Garden, London, in 1641. It will be seen that it may have occurred as a modification of the De Wyck vibrating arm, one of the weights being taken off and the arm hung vertically.

Galileo, about 1581, observed the syringing of a suspended lamp and the regularity of the vibrations recommended a pendulous weight as a time-measurer. He applied it as such successfully, at first employing persons to count the oscillations, but soon effected it by machinery.

Dr. Thomas Young in his lectures on Natural Philosophy and the Mechanic Arts, 1807, Vol. I., p. 19, ascribes the first com-

Digitized by Google

bination of the pendulum with wheel-work to Sanctorius, in 1612.

The *conical* or *spherical* pendulum is one which moves in a circle under the influence of gravitation, it and its suspending cord describing a cone, of which the point of suspension is the apex. The theory of such a pendulum is of a complicated nature, and the instrument, not being used in practical horology, possesses little interest to the non-scientific reader. It is, however, employed in controlling the rotating mechanism of the equatorial telescope. The theory of the ordinary pendulum, which vibrates in a vertical plane, was first clearly elucidated by Huyghens.

The simple pendulum is theoretically an imaginary gravitating point attached by a rigid rod devoid of weight to its point of suspension. As these conditions are impossible in practice, the actual pendulum is a compound pendulum, the weight and shape of the bob and rod serving as elements for determining a point, called the *center of oscillation*, within the pendulum, whose vibrations are performed in the same time as those of the whole mass would be were it concentrated at that point. This being done, the mathematical investigation of the vibrations of this point, oscillating freely under the influence of gravity, is identical with that of the imaginary simple pendulum.

The result of the investigation develops the following laws:

1. At equal distances from the earth's center the times of oscillation of two pendulums are directly proportional to the square roots of their lengths.

2. At different distances from the earth's center the times of vibration are inversely proportional to the square roots of the distances, i. e. to the force of gravitation.

3. The length of a pendulum vibrating seconds is directly proportional to the force of gravity at the place.

From the latter law the force of gravity, that is, the velocity with which a falling body is drawn toward the earth's center at any particular place, is readily deduced. Thus the length of the seconds pendulum at London being, according to Captain Kater's experiments, 3.2616 feet, a body will fall 16.1 nearly, at that place, during the first second of time.

The length of a pendulum beating seconds at the level of the sea in the latitude of London is 39.1393 inches.

Huyghens first observed the difference in the beats of the pendulum at different hights; and extended experiments to ascertain the density of the earth have been made with the pendulum by Professor Airy in the years 1826–28, in deep mines in Cornwall, and later in other places at great depths and hights.

From the first of the foregoing laws it follows that as the length of the pendulum varies in consequence of changes of temperature, the number of its oscillations in a given period, as the sidereal day, will also vary.

Various contrivances have been devised to remedy this defect by keeping the center of suspension and that of oscillation at a uniform distance apart. Such are known as *compensation* pendulums.

Huyghens, about 1656, designed mechanism whereby the small isochronous vibrations of a moving body could be *sustained* and *measured*. He may therefore be considered the inventor of the complete contrivance. This invention is regarded as the most important ever made in reference to practical astronomy. He soon found that the oscillations in circular arcs of different amplitudes are not equal, the wider requiring a rather longer time than the narrower, and that when oscillating in a cycloidal curve the pendulum was free from this defect. As a means of compelling the pendulum into this path, he placed cycloidal checks (*c*, Fig. 3628), whose effect upon the elastic pendulum-rod was such as to cause the center of oscillation of the *bob* to describe the arc of a cycloid, and to make oscillations in equal times whatever might be the extent of the arc described. Mechanical difficulties prevented this beautiful contrivance from being practically useful. See Huyghens's "Horologium Oscillatorium" and other works on horology.

It has been found that pendulums vibrating in very small arcs do not, however, sensibly vary their times of oscillation in consequence of a small proportional increase or decrease in the extent of that arc, and, accordingly, where extreme accuracy is required, the *amplitude* or extent of the oscillation on either side of a vertical line passing through the point of suspension is restricted within narrow limits, and provision is made for preventing, as far as possible, any change in the amplitude.

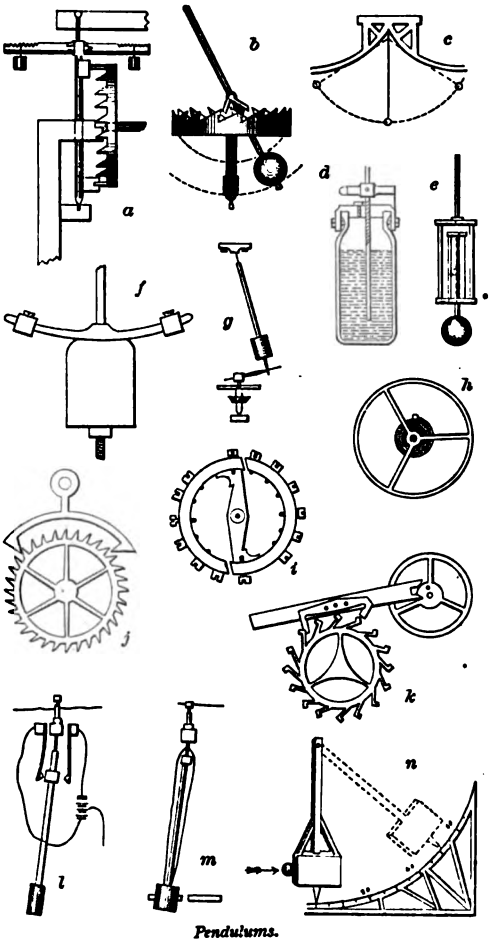
The thin, flat spring by which a clock pendulum is suspended assists in maintaining the uniformity of its oscillations.

The forms of the clock-escapements before Clement of London (1676) invented the *anchor*-escapement are not perfectly known, but were probably on the verge principle, two pallets on the axis of oscillation of the pendulum alternately escaping from the teeth of a crown-wheel propelled by the train.

Clement also devised, about the same time, the mode of suspending the pendulum from a stud by a small piece of watch-spring.

Graham, of London, invented the mercurial compensation pendulum (*d*) about 1700. In it a jar of

Fig. 3628.



Pendulums.

mercury is used for the *bob* or weight. As the pendulum-rod is expanded longitudinally by increased temperature, the expansion of the mercury in the jar carries it to a greater hight therein, and so raises its center of gravity relatively to the rod as to compensate for downward expansion of the latter.

Digitized by Google

Contraction of the rod by cold has the reverse effect, and thus the center of gravity is always kept at the same distance from the point of suspension, the effective length of the pendulum remaining the same, and the beats isochronous.

The gridiron pendulum (*e*) was invented by Harrison, and takes its name from its form, which consisted of a frame of parallel bars of steel and of brass or zinc, while the center bar of steel is fixed at top to the cross-bar connecting the middle brass bars, sliding freely through the lower bars, and bearing the pendulum-bob. The remaining bars are fastened to the cross-piece at both ends, and the uppermost cross-piece is attached to the axis of suspension. It is easy, therefore, to see that the expansion of the steel bars tends to lengthen the pendulum, while that of the brass ones tends to shorten it; and, consequently, if the two expansions exactly counteract each other, the length of the pendulum will remain unchanged. The relative lengths of the brass and steel bars are determined by the expansions of the two metals, which are found by experiments to be generally nearly as 100 to 61.

A compensation pendulum (*f*) has been contrived, in which, by means of a compound bar of metal, a certain portion of the weight of the bob is lifted when heat extends the pendulum-rod. The bent bar is a compound of brass and steel, brazed together brass downward. As brass expands more than steel with a given increment of heat, it carries the weights up with it, raising the center of gravity of the aggregate weight to compensate for the extension of the rod.

The conical pendulum (*g*) is hung by a piece of small round wire. The lower end is connected with and driven in a circle by an arm attached to a vertical, rotating spindle. The pendulum-rod describes a cone in its revolution.

A *rolling pendulum*, consisting of a cylinder oscillating in small spaces on a horizontal plane, has been suggested, but has not evinced any qualities superior to the suspended pendulum describing an arc.

In Reid's *compensation pendulum* (1818) the bob rests in a hollow cylinder of zinc, through which the rounded end of the steel pendulum is passed, the zinc itself being supported by the nut at the end of the rod. As the rod lengthens by heat, carrying the bob downward, the upward expansion of the zinc lengthens the rod and raises the bob to an equal degree.

The pendulum of the watch is an oscillating wheel termed the balance (*h*); this is impelled by the mainspring and train in one direction, and is returned by the force of the hair-spring on the arbor of the balance. It is probably the invention of Dr. Hooke. Jewels were added by Facio of Geneva about 1700. The compensation balance (*i*) was made by Harrison. (See CHRONOMETER.) The circumference is divided into two sections, the ends of which are free. The outer rim, or tire, is of brass, and the inner rim and cross-bar of steel, — these being soldered together so that one expansion counteracts the other. Cold, contracting the inner steel rim, would reduce the circumference; but, as it contracts the outer brass rim still more, an opposite effect is produced, the circumference being enlarged. The effect of expansion is checked in a similar way.

j is Dr. Hooke's anchor-escapement. *k* is the escapement known as the "lever," or "detached lever." The bar to which the pallets are attached turns upon a center-pin, so that the ends of the lever move backward and forward through small arcs, as the pallets are alternately released from the scape-wheel. One end of the lever has a little nick in it, which, as it passes backward and forward, catches a pin upon the balance, and throws it right and left. As the lever, for example, moves to the left, one of the pallets catches a tooth of the scape-wheel, and stops the train; at the same time the balance is thrown round, so that the pin passes out of the nick, and the balance swings free to the extent of the impulse, that is, it is *detached* from the lever. As it swings back under pressure of the hair-spring, the pin catches in the nick again, and, moving the lever back, unlocks the pallet, when instantly the other pallet is caught by another tooth, and the lever throws the balance the other way. The balance is therefore the pendulum of the watch, determining by its isochronal swing the rate of movement of the train.

In electric clocks the pendulum completes a circuit at each vibration. See ELECTRIC CLOCK.

Fig. 3628. *l* represents the controlling pendulum in a series of two or more clocks designed to beat isochronously. It alternately comes into contact with one of two weak springs connected with the poles of a battery having one of its middle plates connected with the earth. The bob of the controlled pendulum (*m*) is a hollow cylinder of soft iron encircled by a coil whose ends are connected through two suspending springs with a wire and the earth respectively, so that during the passage of a current the bob becomes an electro-magnet. Two magnets having their poles turned opposite ways are so fixed that the hollow bob of the pendulum always surrounds one or both of them. Thus the controlled pendulum is either checked or accelerated according as it tends to go faster or slower than the other.

2. The *ballistic pendulum* (*n*) is used for measuring the velocity of projectiles by impact. It was invented by Robins. It consists of a large mass of wood banded with iron, or of a box filled with sandbags, and suspended by iron bars from an axis. The cannon-ball whose velocity is to be determined is fired against the solid block of this pendulum, and the hight to which it is made to oscillate by the blow is shown by an index on a wooden arc, and determines the velocity with which the mass first began to move, when its quantity of motion was equal to that with which the ball struck it.

The velocity at starting is proportional to the square root of the vertical hight ascended, whatever may be the curve; when that curve is circular, as in this instance, the velocities are as the *chords* of the arcs described; so that, if the arc be so graduated that the numbers are proportional to their distances in a straight line from 0, they will correctly express the relative velocities at starting from 0.

3. Foucault's pendulum renders visible the diurnal rotation of the earth. An account of it was presented by M. Foucault to the Academy of Sciences in Paris, September, 1852, and the apparatus was thus arranged: —

At the center of the dome of the Pantheon, a fine wire is attached from which a sphere of metal, 5 inches in diameter, is suspended so as to hang near the floor of the building. The apparatus is put in motion after the manner of a pendulum. Under and concentrical with it is placed a circular table some 20 feet in diameter, the circumference of which is divided into degrees, minutes, etc., and the divisions numbered. Now, supposing the earth to have the diurnal motion imparted to it, which explains the phenomena of day and night, the plane in which this pendulum vibrates will not be affected by this motion, but the table over which the pendulum is suspended will continually change its position by virtue of the diurnal motion, so as to make a complete revolution around its center in 24 hours. Since, then, the table thus revolves, and the pendulum which vibrates over it does not revolve, the consequence is that a line traced upon the table by a point projecting from the bottom of the ball will change its direction relatively to the table from minute to minute and from hour to hour, describing

Digitized by Google

a system of lines radiating from the center of the table. A practiced eye will actually observe that the point on the bottom of the ball does not return to the same point on the table after two successive vibrations. Thus is rendered visible the motion which the table has in common with the earth.

Foucault's experiment was soon afterward tried in the rotunda of the Capitol at Washington, which, though the dome had not then attained its present magnificent proportions, was yet sufficiently high (93 feet in the interior) to insure ample success and afford the many spectators who witnessed the slow apparent change in the plane of vibration of the pendulum relative to the fixed lines described on the pavement, convincing proof of a fact which few perhaps had previously so fully realised.

The experiment has since been repeated at many other places where there were apartments of sufficient hight to exhibit it to advantage.

Foucault afterward made an application of Bohnenberger's gyroscope, which demonstrated the same laws of motion. See GYROSCOPE.

Without tracing the demonstration all through, the result may be stated: over either pole, disturbing causes removed, such as friction, rigidity, or from the air, the pendulum would make a complete (apparent) revolution in 24 hours. The time required would increase as the plane of experiment approached the equator, varying with the sine of the latitude; at the equator no revolution would occur.

The motion is in the direction of the hands of a watch in the northern hemisphere, and in the other direction south of the equator.

4. (*Nautical.*) An instrument for measuring the *heel* or inclination of a ship, so as to assist in the laying of her guns.

5. The *hydrometric* pendulum is a *current-gage*.

Pen'du-lum-hausse. (*Ordnance.*) A species of breech-sight, having a brass bulb at the lower end which keeps it in a vertical position when the carriage is on uneven ground.

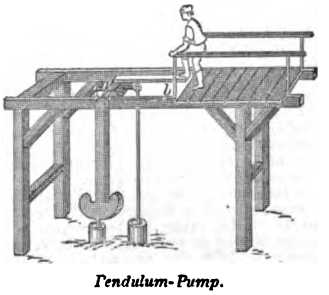
It is made of sheet-brass, and has a slit down its center in which works a slider. It is graduated to degrees and quarters, and for giving the desired elevation a notch in the slider is brought into line with the top of the front sight by lowering or raising the breech of the gun. The hausse has two side branches or trunnions, which rest in the hausse-seat. The seat is made of steel, and is permanently attached to the piece by means of screws.

Pen'du-lum-lev'el. One determining the horizontality of a surface by the verticality of a plumb bob. A mason's or bricklayer's level. See LEVEL.

The plumb or pendulum level, as a geodetic instrument, which shows the horizontal line by means of a line cutting the plummet-line perpendicularly. It consists of two legs, joined together at right angles, with a telescopic sight, and other apparatus; the whole is fixed on a stand by means of a ball and socket. Invented by Picard.

Pen'du-lum-pump. A pump in which a pendulum is employed to govern the reciprocating motion of the piston. In that illustrated, the pendulum is attached to the axis of a beam *a* connected by a transverse bar to the ends of the two piston-rods, and caused to oscillate by depressing a treadle *b*.

Fig 3629.



Pendulum-Pump.

Pen'du-lum-wheel. The balance-wheel of a watch which governs the rate of the motion. See BALANCE.

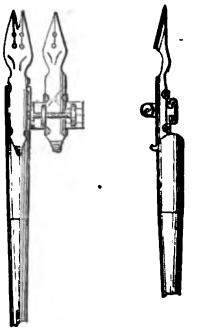
Pen'du-lum-wire. (*Horology.*) Flattened wire, by which the bob of a clock is suspended.

Pen-hold'er. A staff for a writing nib. It is usually a stick with a tubular piece having a pair of bent-in ears which form a socket into which the butt of the nib is slipped.

A more pretentious article, carried in the pocket, has a slipping piece for the pen which may be thus retracted into the handle on occasion.

The stems of pen-holders are of wood, gutta-percha, cork, vulcanite; coiled ribbons of metal or of vulcanite make holders having the pliability of the quill. Sometimes they are of a more costly material around a core of metal or wood. Some varieties may be cited.

Fig. 3630.



Holland's Double Pen.

A pen-holder having an attachment to the shaft, to make a seat for the fingers and thumb, giving a better grip than the simple round barrel.

Toof (1868) has an attachment to secure oblique presentation of the pen.

Holland (1868) has a pair of pens stocked together for ruling parallel lines.

A pen-holder formed of a sheath, to place like a thimble on the end of the finger. A brush may be substituted for the pen.

A tubular sheath to prevent ink from running back on the hand when the holder is inverted.

A pen-holder having marks on which it may be poised, and with the ends so graduated in weight as to form a weighing-balance for letters of different grades of weight.

Holtzapffel's pen-holder for enfeebled hands (English, 1846) has a vertical post which is grasped by the hand and rests on the paper. The pen is held by an arm jointed to the post at an angle of 45°, and is pressed upon the paper by a feeble spring. See also PEN and PENCIL-CASE.

Pen-i-cil'lus. (*Surgical.*) A tent. *Peniculus.*

Pe'nis-syr'inge. (*Surgical.*) A small syringe from 1 to 4 ounces capacity, with a short nozzle, for introduction into the meatus urinarius. Used for injecting the urethra in venereal diseases. It is made of tin, silver, ivory, or hard rubber.

Pen'knife. A pocket-knife with a small blade or blades; so called from its former use in making quill-pens.

The blade is forged from the end of a rod of cast-steel with a light hammer upon a small anvil, and is then cut off. The joint is then finished and a temporary tang drawn out, to be driven into a handle for grinding. The nick called the *nail-hole*, in which the thumb-nail is inserted to open the blade, is stamped by a chisel while the blade is hot.

In hardening, the blades are heated in a coke or charcoal fire, and dipped in the water obliquely: pure water at 40° Fah. The blades are tempered, twelve or more at a time, on a plate of iron or copper. They are arranged close together on their backs, and lean at an angle against each other. As they come down to the temper, they are picked out with small pliers and thrown into the water, if necessary. Other blades are then thrust forward from the cooler parts of the plate to take their places. They are then finished on the glazer and polishing-wheel.

Pen-mak'er. A tool formed like a pair of pinchers for making quill-pens.

The jaws of the tool are convex and concave to receive the point of a quill which has one half cut away; and, by closing, a set of small dies form the outline of the pen, while a little blade in the middle makes the slit.

Digitized by Google

A machine on this principle was invented by Bramah, and by it six double-pointed pens were made from each quill. A very large number of pens were made in this way before the introduction of steel-pens.

Pen'nant. 1. A rope to which a purchase is hooked. See PENDANT.

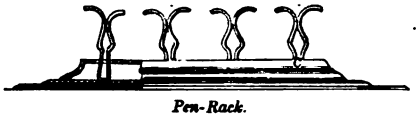
2. A long, narrow streamer borne at the mast-head by vessels of war. A *penon*.

The head is 6.24 inches to a length of 70 feet; 5.76 to 55 feet; 5.24 inches to 40 feet; 4.8 inches to 30 feet; 4.2 inches to 25 feet.

Pen'nis-tone. (*Fabric.*) A coarse woolen frieze.

Pen-rack. A piece of desk-furniture to hold an idle pen. It may consist of a row of hooks on

Fig. 3681.

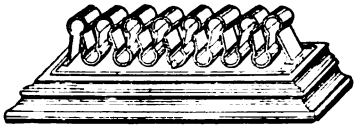


Pen-Rack.

branches rising from the base of the inkstand, or, as in the example, spring clips which embrace the pen-holder with sufficient strength to retain it and yet yield it to the writer.

A coil of wire slightly extended answers the same purpose.

Fig. 3682.



Spring Pen-Rack.

Pen-stock. 1. A conduit for water, usually of boards, and notably a trough of planks, which conducts the water to a water-wheel. It begins at the end of the *race*, of which it forms a continuation, and ends at the *gate*, which is lifted to discharge the water on to the wheel. A *shuttle* or *pen-trough*.

2. A sluice or flood gate restraining the waters of a mill pond or race.

3. A flood-gate used in inundating certain parts of fortified works.

Pen'ta-graph. See PANTOGRAPH.

Pent'house. 1. (*Carpentry.*) A projection over a door, entrance, window, or a flight of steps, etc., for protection from weather.

2. (*Ordnance.*) A small house, made of boards united by hooks and staples, for protecting a gun and its carriages mounted *en barbette* from the weather.

Pent-roof. (*Carpentry.*) A roof with *two* equal sloping sides. A compass-roof. A shed or lean-to roof.

Pep'per-box. A small box or caster for dredging pepper on to meat or other food.

Black-pepper is a vine with a knotty stem, which unpruned will reach the hight of 30 feet, but on Singapore Island, and probably elsewhere, is trained on poles of about 12 feet high, which are grasped by the tendrils of the vine. The branches are brittle; the leaves deep green, heart-shaped, and abundant; the blossom a cluster of small, white, almost odorless flowers. The fruit hangs in clusters of 40 or 50 grains in a bunch. At full size it is green, red at maturity, black after being picked, and then shriveled by drying on mats in the sun.

White-pepper is macerated in water until the black cuticle can be rubbed off and the grains again dried in the sun.

Pliny says that pepper was brought from India; "and what was he, gladly would I know, that ventured first to bite of pepper and use it in his meats? Who might he be that, to provoke his appetite and find himself a good stomach, could not make a shift with fasting and hunger only?"

Capsicum (red-pepper) appears to have been unknown to the ancients. It is probably a West India production.

Per-am'bu-la'tor. 1. A machine for measuring a distance traveled. It usually consists of a wheel of known circumference, say 99 inches or half a rod, with a register to record the number of revolutions.

It may be driven by hand or attached to the wheel of a carriage, as in those described by Vitruvius and those among the effects of the deceased Emperor Commodus. The latter not only measured the distance traveled, but also pointed out the hours. A *pedometer*, *odometer*, or *surveying-wheel*. See ODOMETER.

In one form of this instrument, the wheel, 8¼ feet in circumference, is journaled in the end of a stock, so that it may be lifted out of contact with the ground; on the axis of the wheel is a pinion which works another pinion on the end of a rod having at its upper part an endless screw which moves a train of gearing that gives motion to two hands on an index registering the distance to miles, furlongs, rods, and yards. The instrument is furnished with a stop, so that after measuring a certain distance it may be carried on without altering the position of the hands.

2. A child's carriage propelled from behind.

Per'bend. (*Masonry.*) A *header*-stone which passes through the whole thickness of a wall.

Per-cale'. (*Fabric.*) A cotton goods, printed or plain, and with a linen finish.

Per-ca-line'. (*Fabric.*) Fine French printed cotton goods.

Perch. 1. (*Vehicle.*) *a.* A pole connecting the fore and hind gears of a spring carriage. It has lateral strengthening-bars, called *hind-hounds*, in a wagon.

It is strengthened on the under side by the *perch-plate*.

The *strap* passes from the perch to the foot of the *kingbolt*.

b. An elevated seat for the driver.

2. A console. A bracket.

Per'co-la-tor. A filter. The term is specifically applied to the filter of the pharmacist; and to the French coffee-pot, in which the boiling water is filtered through the ground coffee.

The coffee-percolator was invented by Benjamin Thompson, Count Rumford. It consists of an upper cylindrical vessel with a perforated bottom, in which the ground coffee is placed and covered with a perforated disk having a stem by which it may be pressed down so as to compact the coffee and allow boiling water poured thereon to percolate the mass and pass into the coffee-pot below.

In Jones's percolator the lower vessel is heated by a spirit-lamp, and the generated steam forces the water up through a pipe at the side and filters through the coffee placed in a vessel with a perforated bottom above. See COFFEE-POT.

Per-cus'sion-cap. A small cylinder of copper adapted to fit on the nipple of a gun and having a flake of fulminating powder inside, which is exploded by the fall of the hammer upon the nipple, communicating fire through the latter to the charge in the gun.

Detonating powder or pellets were used in 1807, having been patented in England by Rev. Mr. Forsyth for use with artillery; but the charging of caps therewith was a later invention. The percussion principle had a hard struggle with the old flint-lock in the armies of Europe and America until long after it was universally adopted for sporting purposes.

It was not introduced into the United States service until 1842. Caps were invented in England in 1814 by Joshua Shaw. He came to the United States for the purpose of procuring a patent, but was refused as an alien. In 1822, he patented a percussion-lock; in 1828, the percussion-wafer primer. He subsequently received $17,000 from the United States government for his improvements, and died in 1860. Caps for small-arms are made of thin sheet-copper, those for sporting-guns, etc., usually having longitudinal striations.

The composition used in the United States service is fulminate of mercury mixed with half its weight of niter. This renders the fulminate less explosive, and gives body to its flame; it is protected by a drop of copal varnish, which soon dries in a thin film, preventing access of decomposing agents. Tin-foil is also employed for the same purpose.
